*Design Considerations.* An acceptable radiative temperature increase ( $T_{\text{rad}} - T_i$ ) of 20 to 25°F is often adopted for normal clothed occupants using infrared heating. The corresponding required watt density

for infrared heaters is 30 to 37 W/ft<sup>2</sup>. At a mounting height of 11 ft, two heaters having a spacing of 6.5 ft can provide a watt density of 33 W/ft<sup>2</sup> and cover an area of 12 × 13 ft. The mounting height of the infrared heaters should not be lower than 10 ft. Otherwise the occupants may feel discomfort from the overhead radiant beam. Refer to Grimm and Rosaler (1990), *Handbook of HVAC Design*, for details.

Gas and electric infrared heaters should not be used in places where there is danger of ignitable gas or materials that may decompose into toxic gases.

## 9.11 Refrigeration Systems

---

### Classifications of Refrigeration Systems

Most of the refrigeration systems used for air-conditioning are vapor compression systems. Because of the increase in the energy cost of natural gas in the 1980s, the application of absorption refrigeration systems has dropped sharply. According to Commercial Buildings Characteristics 1992, absorption refrigeration systems have a weight of less than 3% of the total amount of refrigeration used in commercial buildings in the United States. Air expansion refrigeration systems are used mainly in aircraft and cryogenics.

Refrigeration systems used for air-conditioning can be classified mainly in the following categories:

- Direct expansion (DX) systems and heat pumps
- Centrifugal chillers
- Screw chillers
- Absorption systems

Each can be either a single-stage or a multistage system.

### Direct Expansion Refrigeration Systems

A *direct expansion refrigeration (DX) system*, or simply *DX system*, is part of the packaged air-conditioning system. The DX coil in the packaged unit is used to cool and dehumidify the air directly as shown in [Figure 9.11.1\(a\)](#). According to EIA Commercial Buildings Characteristics 1992, about 74% of the floor space of commercial buildings in the United States was cooled by DX refrigeration systems.

Refrigerants R-22 and R-134a are widely used. Azeotropics and near azeotropics are the refrigerants often used for low-evaporating-temperature systems like those in supermarkets. Because of the limitation of the size of the air system, the refrigeration capacity of DX systems is usually 3 to 100 tons.

*Components and Accessories.* In addition to the DX coil, a DX refrigeration system has the following components and accessories:

- *Compressor(s)* — Both reciprocating and scroll compressors are widely used in DX systems. Scroll compressors are gradually replacing reciprocating compressors because they have fewer parts and comparatively higher efficiency. For large DX systems, multiple compressors are adopted.
- *Condensers* — Most DX systems in rooftop packaged units are air cooled. Water-cooled condensers are adopted mainly for DX systems in indoor packaged units due to their compact volume. Evaporative-cooled condensers are also available.
- *Refrigeration feed* — Thermostatic expansion valves are widely used as the throttling and refrigerant flow control devices in medium and large DX systems, whereas capillary tubes are used in small and medium-sized systems.
- *Oil lubrication* — R-22 is partly miscible with mineral oil. Since R-134a is not miscible with mineral oil, synthetic polyolester oil should be used. For medium and large reciprocating compressors, an oil pump of vane, gear, or centrifugal type is used to force the lubricating oil to the bearings and moving surfaces via grooves. For small reciprocating compressors, splash lubrication using the rotation of the crankshaft and the connecting rod to splash oil onto the bearing surface and the cylinder walls is used.

A scroll compressor is often equipped with a centrifugal oil pump to force the oil to lubricate the orbiting scroll journal bearing and motor bearing. For the scroll contact surfaces, lubrication is provided by the small amount of oil entrained in the suction vapor.

**FIGURE 9.11.1** A DX refrigeration system: (a) schematic diagram; (b) four-way reversing valve, cooling mode; and (c) four-way reversing valve, heating mode.

- *Refrigerant piping* — Refrigerant piping transports refrigerant through the compressor, condenser, expansion valve, and DX coil to provide the required refrigeration effect. As shown in Figure 9.11.1(a), from the exit of the DX coil to the inlet of the compressor(s) is the *suction line*. From the outlet of the compressor to the inlet of the air-cooled condenser is the *discharge line*. From the exit of the condenser to the inlet of the expansion valve is the *liquid line*.

Halocarbon refrigerant pipes are mainly made of copper tubes of L type. In a packaged unit, refrigerant pipes are usually sized and connected in the factory. However, the refrigerant pipes in field-built and split DX systems for R-22 are sized on the basis of a pressure drop of 2.91 psi corresponding to a change of saturated temperature  $\Delta T_{\text{suc}}$  of 2°F at 40°F for the suction line and a pressure drop of 3.05 psi corresponding to 1°F at 105°F for the discharge and liquid line. The pressure drop includes pressure losses of pipe and fittings. Refrigerant pipes should also be sized to bring back the entrained oil from the DX coil and condenser through the discharge and suction lines.

Accessories include a filter dryer to remove moisture from the refrigerant, strainer to remove foreign matter, and sight glass to observe the condition of refrigerant flow (whether bubbles are seen because of the presence of flash gas in the liquid line).

*Capacity Controls.* In DX systems, control of the mass flow rate of refrigerant through the compressor(s) is often used as the primary refrigeration capacity control. Row or intertwined face control at the DX coil is also used in conjunction with the capacity control of the compressor(s).

Three methods of capacity controls are widely used for reciprocating and scroll compressors in DX systems:

- *On-off control* — Starting or stopping the compressor is a kind of step control of the refrigerant flow to the compressor. It is simple and inexpensive, but there is a 100% variation in capacity for DX systems installed with only a single compressor. On-off control is widely used for small systems or DX systems with multiple compressors.
- *Cylinder unloader* — For a reciprocating compressor having multiple cylinders, a cylinder unloader mechanism bypasses the compressed gas from one, two, or three cylinders to the suction chamber to reduce the refrigeration capacity and compressing energy.
- *Speed modulation* — A two-speed motor is often used to drive scroll or reciprocating compressors so that the capacity can be reduced 50% at lower speed.

*Safety Controls.* In *low- and high-pressure control*, the compressor is stopped when suction pressure drops below a preset value, the cut-in pressure, or the discharge pressure of the hot gas approaches a dangerous level, the cut-out pressure.

In *low-temperature control*, a sensor is mounted on the outer pipe surface of the DX coil. When the surface temperature drops below 32°F, the controller stops the compressor to prevent frosting.

If the pressure of the oil discharged from the pump does not reach a predetermined level within a certain period, a mechanism in *oil pressure failure control* opens the circuit contact and stops the compressor.

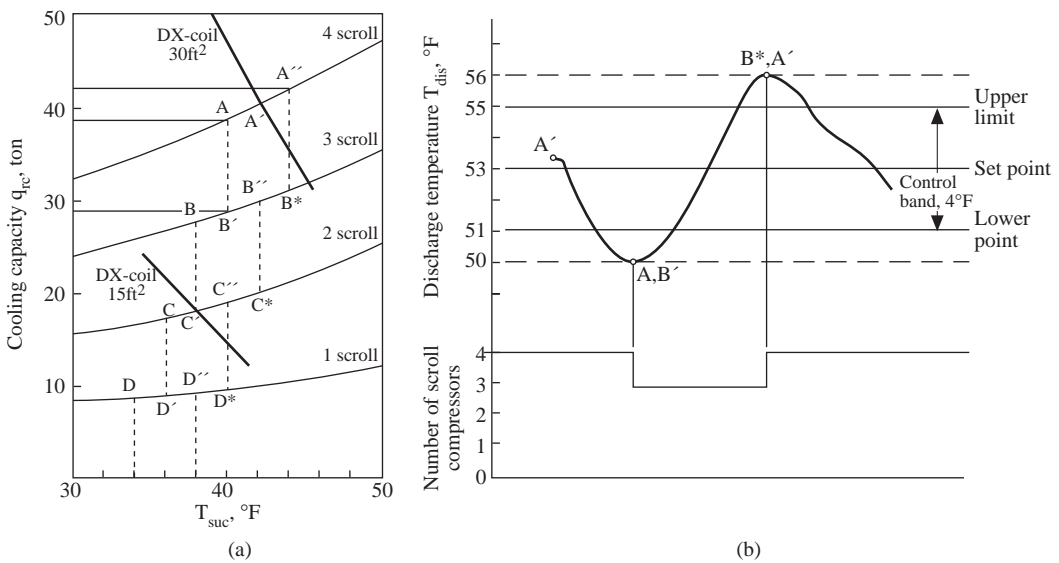

In *motor overload control*, a sensor is used to measure the temperature of the electric winding or the electric current to protect the motor from overheating and overloading.

*Pump-down control* is an effective means of preventing the migration of the refrigerant from the DX coil (evaporator) to the crankcase of the reciprocating compressor. This prevents mixing of refrigerant and oil to form slugs, which may damage the compressor.

When a rise of suction pressure is sensed by a sensor, a DDC controller opens a solenoid valve and the liquid refrigerant enters the DX coil. As the buildup of vapor pressure exceeds the cut-in pressure, the compressor starts. When the DX system needs to shut down, the solenoid valve is closed first; the compressor still pumps the gaseous refrigerant to the condenser. As the suction pressure drops below the cut-in pressure, the compressor stops.

*Full- and Part-Load Operations.* Consider a DX system in a rooftop packaged unit using four scroll compressors, each with a refrigeration capacity of 10 tons at full load. Performance curves of the condensing unit and the DX coil of this DX system are shown in Figure 9.11.2(a). A DDC controller actuates on–off for these scroll compressors based on the signal from a discharge air temperature  $T_{dis}$  sensor.

On a hot summer day, when the rooftop packaged unit starts with a DX coil load or refrigeration capacity,  $q_{rc} \approx 40$  tons, all four scroll compressors are operating. The operating point is at A' with a suction temperature  $T_{suc}$  of about 42°F, and the discharge air temperature  $T_{dis}$  is maintained around 53°F. As the space cooling load  $q_{ri}$  as well as  $T_{dis}$  decreases, the required DX coil load  $q_{rl}$  drops to 35 tons. Less evaporation in the DX coil causes a decrease of  $T_{suc}$  to about 40°F, and the operating point may move downward to point A with a DX coil refrigeration capacity of 39 tons. Since  $q_{rc} > q_{rl}$ ,  $T_{dis}$  drops continually until it reaches 50°F, point A in Figure 9.11.2(b), and the DDC controller shuts down one of the scroll compressors. The operating point immediately shifts to B' on the three-compressor curve.

**FIGURE 9.11.2** Capacity control of a DX refrigeration system: (a) performance curves and operating points and (b) locus of control point.

Because the refrigeration capacity at point B'  $q_{rc}$  is 29 tons, which is less than the required  $q_{rl} = 35$  tons, both  $T_{dis}$  and  $T_{suc}$  rise. When the operating point moves up to B\* and  $T_{dis}$  reaches 56°F, the DDC controller starts all four scroll compressors at operating point A'' with a refrigeration capacity of 42 tons. Since  $q_{rc} > q_{rl}$ , the operating point again moves downward along the four-compressor curve and forms an operating cycle A''AB' and B\*. The timing of the operating period on four- or three-compressor performance curves balances any required  $q_{rl}$  between 29 and 42 tons. Less evaporation at part load in the DX coil results in a greater superheating region and therefore less refrigeration capacity to balance the reduction of refrigeration capacity of the compressor(s) as well as the condensing unit. The condition will be similar when  $q_{rl} < 30$  tons, only three- or two-compressor, or two- or one-compressor, or even on–off of one compressor forms an operating cycle.

*Main Problems in DX Systems*

- *Liquid slugging* is formed by a mixture of liquid refrigerant and oil. It is formed because of the flooding back of liquid refrigerant from the DX coil to the crankcase of the reciprocating compressor due to insufficient superheating. It also may be caused by migration of liquid refrig-

erant from the warmer indoor DX coil to the colder outdoor compressor during the shut-down period in a split packaged unit. Liquid slugging dilutes the lubricating oil and causes serious loss of oil in the crankcase of the reciprocating compressor. Liquid slugging is incompressible. When it enters the compression chamber of a reciprocating compressor, it may damage the valve, piston, and other components. Pump-down control and installation of a crankcase heater are effective means of preventing liquid refrigerant migration and flooding back.

- *Compressor short cycling* — For on–off control, too short a cycle, such as less than 3 min, may pump oil away from the compressor or damage system components. It is due mainly to a too close low-pressure control differential or to reduced air flow.
- *Defrosting* — If the surface of a DX coil is 32°F or lower, frost accumulates on it. Frost blocks the air passage and reduces the rate of heat transfer. It should be removed periodically. The process of removing frost is called defrosting.

Air at a temperature above 36°F, hot gas inside the refrigerant tubes and an installed electric heating element can be used for defrosting. The defrosting cycle is often controlled by sensing the temperature or pressure difference of air entering the DX coil during a fixed time interval.

- *Refrigerant charge* — Insufficient refrigerant charge causes lower refrigeration capacity, lower suction temperature, and short on–off cycles. Overcharging refrigerant may cause a higher condensing pressure because part of the condensing surface becomes flooded with liquid refrigerant.

## Heat Pumps

A *heat pump* in the form of a packaged unit is also a *heat pump system*. A heat pump can either extract heat from a heat source and reject heat to air and water at a higher temperature for heating, or provide refrigeration at a lower temperature and reject condensing heat at a higher temperature for cooling. During summer, the heat extraction, or refrigeration effect, is the useful effect for cooling in a heat pump. In winter, the rejected heat and the heat from a supplementary heater provide heating in a heat pump.

There are three types of heat pumps: air-source, water-source, and ground-coupled heat pumps. Ground-coupled heat pumps have limited applications. Water-source heat pump systems are covered in detail in a later section.

*Air-Source Heat Pump.* An *air-source heat pump*, or *air-to-air heat pump*, is a DX system with an additional four-way reversing valve to change the refrigerant flow from cooling mode in summer to heating mode in winter and vice versa. The variation in connections between four means of refrigerant flow — compressor suction, compressor discharge, DX coil exit, and condenser inlet — causes the function of the indoor and outdoor coils to reverse. In an air-source heat pump, the coil used to cool or to heat the recirculating/outdoor air is called the *indoor coil*. The coil used to reject heat to or absorb heat from the outside atmosphere is called the *outdoor coil*. A short capillary or restrict tube is often used instead of a thermostatic expansion valve. Both reciprocating and scroll compressors are used in air-source heat pumps. R-22 is the refrigerant widely used. Currently available air-source heat pumps usually have a cooling capacity of 1½ to 40 tons.

*Cooling and Heating Mode Operation.* In *cooling mode operation*, as shown in Figure 9.11.1(b), the solenoid valve is deenergized and drops downward. The high-pressure hot gas pushes the sliding connector to the left end. The compressor discharge connects to the outdoor coil, and the indoor coil connects to the compressor inlet.

In *heating mode operation*, as shown in Figure 9.11.1(c), the solenoid plunger moves upward and pushes the slide connector to the right-hand side. The compressor discharge connects to the indoor coil, and the outdoor coil exit connects to the compressor suction.

*System Performance.* The performance of an air-source heat pump depends on the outdoor air temperature  $T_o$ , in °F as well as the required space heating load  $q_{th}$ . During cooling mode operation, both the refrigeration capacity  $q_{rc}$ , in Btu/hr, and EER for the heat pump  $EER_{hp}$ , in Btu/hr.W, increase as  $T_o$  drops.

During heating mode operation, the heating capacity  $q_{hp}$ , in Btu/hr, and  $COP_{hp}$  decrease, and  $q_{rh}$  increases as the  $T_o$  drops. When  $q_{rh} > q_{hp}$ , supplementary heating is required. If  $COP_{hp}$  drops below 1, electric heating may be more economical than a heat pump.

If on–off is used for compressor capacity control for an air-source heat pump in a split packaged unit, refrigerant tends to migrate from the warmer outdoor coil to the cooler indoor coil in summer and from the warmer indoor coil to the cooler outdoor coil in winter during the off period. When the compressor starts again, 2 to 5 min of reduced capacity is experienced before the heat pump can be operated at full capacity. Such a loss is called a *cycling loss*.

In winter, most air-source heat pumps switch from the heating mode to cooling mode operation and force the hot gas to the outdoor coil to melt frost. After the frost is melted, the heat pump is switched back to heating mode operation. During defrosting, supplementary electric heating is often necessary to prevent a cold air supply from the air-source heat pump.

**Minimum Performance.** ASHRAE/IES Standard 90.1-1989 specifies a minimum performance for air-cooled DX systems in packaged units as covered in Section 9.7. For air-cooled, electrically operated rooftop heat pumps (air-source heat pumps), minimum performance characteristics are:

Cooling EER	8.9
Heating, COP (at $T_oF = 47°F$ )	3.0
Heating, COP (at $T_oF = 17°F$ )	2.0

### Centrifugal Chillers

A *chiller* is a refrigeration machine using a liquid cooler as an evaporator to produce chilled water as the cooling medium in a central air-conditioning system. A *centrifugal chiller*, as shown in Figure 9.11.3(a), is a refrigeration machine using a centrifugal compressor to produce chilled water. It is often a factory-assembled unit with an integrated DDC control system and sometimes may separate into pieces for transportation. A centrifugal chiller is also a *centrifugal vapor compression refrigeration system*.

**Refrigerants.** According to Hummel et al. (1991), in 1988 there were about 73,000 centrifugal chillers in the United States. Of these, 80% use R-11, 10% use R-12, and the remaining 10% use R-22 and others. As mentioned in Section 9.4, production of CFCs, including R-11 and R-12, ceased at the end of 1995 with limited exception for service. R-123 (HCFC) will replace R-11. The chiller's efficiency may drop 2 to 4%, and a capacity reduction of 5% is possible. R-123 has low toxicity. Its allowable exposure limit was raised to 50 ppm in 1997 from 30 ppm in 1993 by its manufacturers. A monitor and alarm device to detect R-123 in air should be installed in plant rooms and places where there may be refrigerant leaks.

R-134a (HFC) will replace R-12. According to Lowe and Ares (1995), as a result of the changeout from R-12 to R-134a for a 5000-hp centrifugal chiller in Sears Tower, Chicago, its speed increased from 4878 to 5300 rpm, its cooling capacity is 12 to 24% less, and its efficiency is 12 to 16% worse.

**System Components.** A centrifugal chiller consists of a centrifugal compressor, an evaporator or liquid cooler, a condenser, a flash cooler, throttling devices, piping connections, and controls. A purge unit is optional.

- Centrifugal compressor — According to the number of internally connected impellers, the centrifugal compressor could have a single, two, or more than two stages. A two-stage impeller with a flash cooler is most widely used because of its higher system performance and comparatively simple construction. Centrifugal compressors having a refrigeration capacity less than 1200 tons are often hermetic. Very large centrifugal compressors are of open type. A gear train is often required to raise the speed of the impeller except for very large impellers using direct drive.
- Evaporator — Usually a liquid cooler of flooded shell-and-tube type evaporator is adopted because of its compact size and high rate of heat transfer.
- Condenser — Water-cooled, horizontal shell-and-tube condensers are widely used.

**FIGURE 9.11.3** A two-stage water-cooled centrifugal chiller: (a) schematic diagram and (b) centrifugal compressor performance map at constant speed.

- Flash cooler — For a two-stage centrifugal compressor, a single-stage flash cooler is used. For a three-stage compressor, a two-stage flash cooler is used.
- Orifice plates and float valves — Both multiple-orifice plates such as that shown in Figure 9.11.3(a) and float valves are used as throttling devices in centrifugal chillers.
- Purge unit — R-123 has an evaporating pressure  $p_{ev} = 5.8$  psia at 40°F, which is lower than atmospheric pressure. Air and other noncondensable gases may leak into the evaporator through cracks and gaps and usually accumulate in the upper part of the condenser. These noncondensable gases raise the condensing pressure, reduce the refrigerant flow, and lower the rate of heat transfer. A purge unit uses a cooling coil to separate the refrigerant and water from the noncondensable gases and purge the gases by using a vacuum pump.

*Performance Ratings.* The refrigeration cycle of a typical water-cooled, two-stage centrifugal chiller with a flash cooler was covered in Section 9.4. Centrifugal chillers have the same refrigeration capacity as centrifugal compressors, 100 to 10,000 tons. According to ARI Standard 550-88, the refrigeration capacity of a centrifugal chiller is rated as follows:

Chilled water temperature leaving evaporator $T_{el}$ :	100% load 44°F 0% load 44°F
Chilled water flow rate:	2.4 gpm/ton
Condenser water temperature entering condenser $T_{ce}$ :	100% load 85°F 0% load 60°F
Condenser water flow rate:	3.0 gpm/ton
Fouling factor in evaporator and condenser:	0.00025 hr.ft <sup>2</sup> .°F/Btu

The integrated part-load value (IPLV) of a centrifugal chiller or other chillers at standard rating conditions can be calculated as:

$$\text{IPLV} = 0.1(A + B)/2 + 0.5(B + C)/2 + 0.3(C + D)/2 + 0.1D \quad (9.11.1)$$

where  $A$ ,  $B$ ,  $C$ , and  $D$  = kW/ton or COP at 100, 75, 50, and 25% load, respectively. If the operating conditions are different from the standard rating conditions, when  $T_{el}$  is 40 to 50°F, for each °F increase or decrease of  $T_{el}$ , there is roughly a 1.5% difference in refrigeration capacity and energy use; when  $T_{ce}$  is between 80 to 90°F, for each °F of increase or decrease of  $T_{ce}$ , there is roughly a 1% increase or decrease in refrigeration capacity and 0.6% in energy use.

ASHRAE/IES Standard 90.1-1989 and ARI Standard 550-88 specify the minimum performance for water-cooled water chillers from January 1, 1992:

	COP	IPLV
≥300 tons	5.2	5.3
≥150 tons < 300 tons	4.2	4.5
<150 tons	3.8	3.9

COP = 5.0 is equivalent to about 0.70 kW/ton. New, installed centrifugal chillers often have an energy consumption of 0.50 kW/ton.

Air-cooled centrifugal chillers have COPs from 2.5 to 2.8. Their energy performance is far poorer than that of water-cooled chillers. Their application is limited to locations where city water is not allowed to be used as makeup water for cooling towers.

*Capacity Control.* The refrigeration capacity of a centrifugal chiller is controlled by modulating the refrigerant flow at the centrifugal compressor. There are mainly two types of capacity controls: varying the opening and angle of the inlet vanes, and using an adjustable-frequency AC inverter to vary the rotating speed of the centrifugal compressor.

When the opening of the inlet vanes has been reduced, the refrigerant flow is throttled and imparted with a rotation. The result is a new performance curve at lower head and flow. If the rotating speed of a centrifugal compressor is reduced, it also has a new performance curve at lower volume flow and head. Inlet vanes are inexpensive, whereas the AC inverter speed modulation is more energy efficient at part-load operation.

*Centrifugal Compressor Performance Map.* Figure 9.11.3(b) shows a single-stage, water-cooled centrifugal compressor performance map for constant speed using inlet vanes for capacity modulation. A performance map consists of the compressor's performance curves at various operating conditions. The performance curve of a centrifugal compressor shows the relationship of volume flow of refrigerant  $\dot{V}_r$

and its head lift  $\Delta p$  or compression efficiency  $\eta_{cp}$  at that volume flow. It is assumed that  $\eta_{cp}$  for a two-stage compressor is equal to the average of the two single-stage impellers having a head of their sum.

On the map, the required *system head curve* indicates the required system head lift at that volume flow of refrigerant. The intersection of the performance curve and the required system head curve is called the *operating point* O, P, Q, R, ... as shown in Figure 9.11.3(b). One of the important operating characteristics of a centrifugal chiller (a centrifugal vapor compression refrigeration system as well) is that the required system head lift is mainly determined according to the difference in condensing and evaporating pressure  $\Delta p_{c-e} = (p_{con} - p_{ev})$ . The pressure losses due to the refrigerant piping, fittings, and components are minor.

In Figure 9.11.3(b), the abscissa is the percentage of design volume flow of refrigerant, %  $\dot{V}_r$ , or load ratio; the ordinate is the percentage of design system head  $\Delta H_{s,d}$ , or percentage of design temperature lift  $(T_{con} - T_{ev})$ . Here load ratio LR is defined as the ratio of the refrigeration load to the design refrigeration load  $q_r/q_{r,d}$ . There are three schemes of required system head curves:

- Scheme A —  $T_{ce} = \text{constant}$  and  $T_{el} = \text{constant}$
- Scheme B —  $T_{el} = \text{constant}$  and a drop of 2.5°F of  $T_{ce}$  for each 0.1 reduction of load ratio
- Scheme C — A reset of  $T_{el}$  of 1°F increase and a drop of 2.5°F of  $T_{ce}$  for each 0.1 reduction of load ratio

At design  $\dot{V}_r$  and system head  $H_{s,d}$ ,  $\eta_{cp} = 0.87$ . As  $\dot{V}_r$ , load ratio, and required system head  $\Delta p$  decrease,  $\eta_{cp}$  drops accordingly.

Surge is a unstable operation of a centrifugal compressor or fan resulting in vibration and noise. In a centrifugal chiller, surge occurs when the centrifugal compressor is unable to develop a discharge pressure that satisfies the requirement at the condenser. A centrifugal compressor should never be operated in the surge region.

*Part-Load Operation.* During part-load operation, if  $T_{el}$  and  $T_{ce}$  remain constant, the evaporating temperature  $T_{ev}$  tends to increase from the design load value because there is a greater evaporating surface and a smaller temperature difference  $(T_{el} - T_{ev})$ . Similarly,  $T_{con}$  tends to decrease.

The ratio of actual compressor power input at part load to the power input at design load may be slightly higher or lower than the load ratios, depending on whether the outdoor wet bulb is constant or varying at part load or whether there is a  $T_{el}$  reset; it also depends on the degree of drop of  $\eta_{cp}$  at part load.

*Specific Controls.* In addition to generic controls, specific controls for a centrifugal chiller include:

- Chilled water leaving temperature  $T_{el}$  and reset
- Condenser water temperature  $T_{ce}$  control
- On and off of multiple chillers based on actual measured coil load
- Air purge control
- Safety controls like oil pressure, low-temperature freezing protection, high condensing pressure control, motor overheating, and time delaying

*Centrifugal Chillers Incorporating Heat Recovery.* A HVAC&R heat recovery system converts waste heat or waste cooling from any HVAC&R process into useful heat and cooling. A heat recovery system is often subordinate to a parent system, such as a heat recovery system to a centrifugal chiller.

A centrifugal chiller incorporating a heat recovery system often uses a double-bundle condenser in which water tubes are classified as tower bundles and heating bundles. Heat rejected in the condenser may be either discharged to the atmosphere through the tower bundle and cooling tower or used for heating through the heating bundle. A temperature sensor is installed to sense the temperature of return hot water from the heating coils in the perimeter zone. A DDC controller is used to modulate a bypass three-way valve which determines the amount of condenser water supplied to the heating bundle. The tower and heating bundles may be enclosed in the same shell, but baffle sheets are required to guide the water flows.

A centrifugal chiller incorporating a heat recovery system provides cooling for the interior zone and heating for the perimeter zone simultaneously in winter with a higher  $COP_{hr}$ . However, it needs a higher condenser water-leaving temperature  $T_{ci}$  of 105 to 110°F, compared with 95°F or even lower in a cooling-only centrifugal chiller. An increase of 10 to 12°F of the difference ( $T_{con} - T_{ev}$ ) requires an additional 10 to 15% power input to the compressor. For a refrigeration plant equipped with multiple chillers, it is more energy efficient and lower in first cost to have only part of them equipped with double-bundle condensers.

### Screw Chillers

A *screw chiller* or a *helical rotary chiller* is a refrigeration machine using a screw compressor to produce chilled water. A factory-fabricated and assembled screw chiller itself is also a screw vapor compression refrigeration system.

Twin-screw chillers are more widely used than single-screw chillers. A twin-screw chiller consists of mainly a twin-screw compressor, a flooded shell-and-tube liquid cooler as evaporator, a water-cooled condenser, throttling devices, an oil separator, an oil cooler, piping, and controls as shown in Figure 9.11.4(a). The construction of twin-screw compressors has already been covered. For evaporator, condenser, and throttling devices, they are similar to those in centrifugal chillers. Most twin-screw chillers have a refrigeration capacity of 100 to 1000 tons.

Following are the systems characteristics of screw chillers.

**Variable Volume Ratio.** The ratio of vapor refrigerant trapped within the interlobe space during the intake process  $V_{in}$  to the volume of trapped hot gas discharged  $V_{dis}$  is called the *built-in volume ratio* of the twin-screw compressor  $V_1 = V_{in}/V_{dis}$ , or simply *volume ratio*, all in  $ft^3$ .

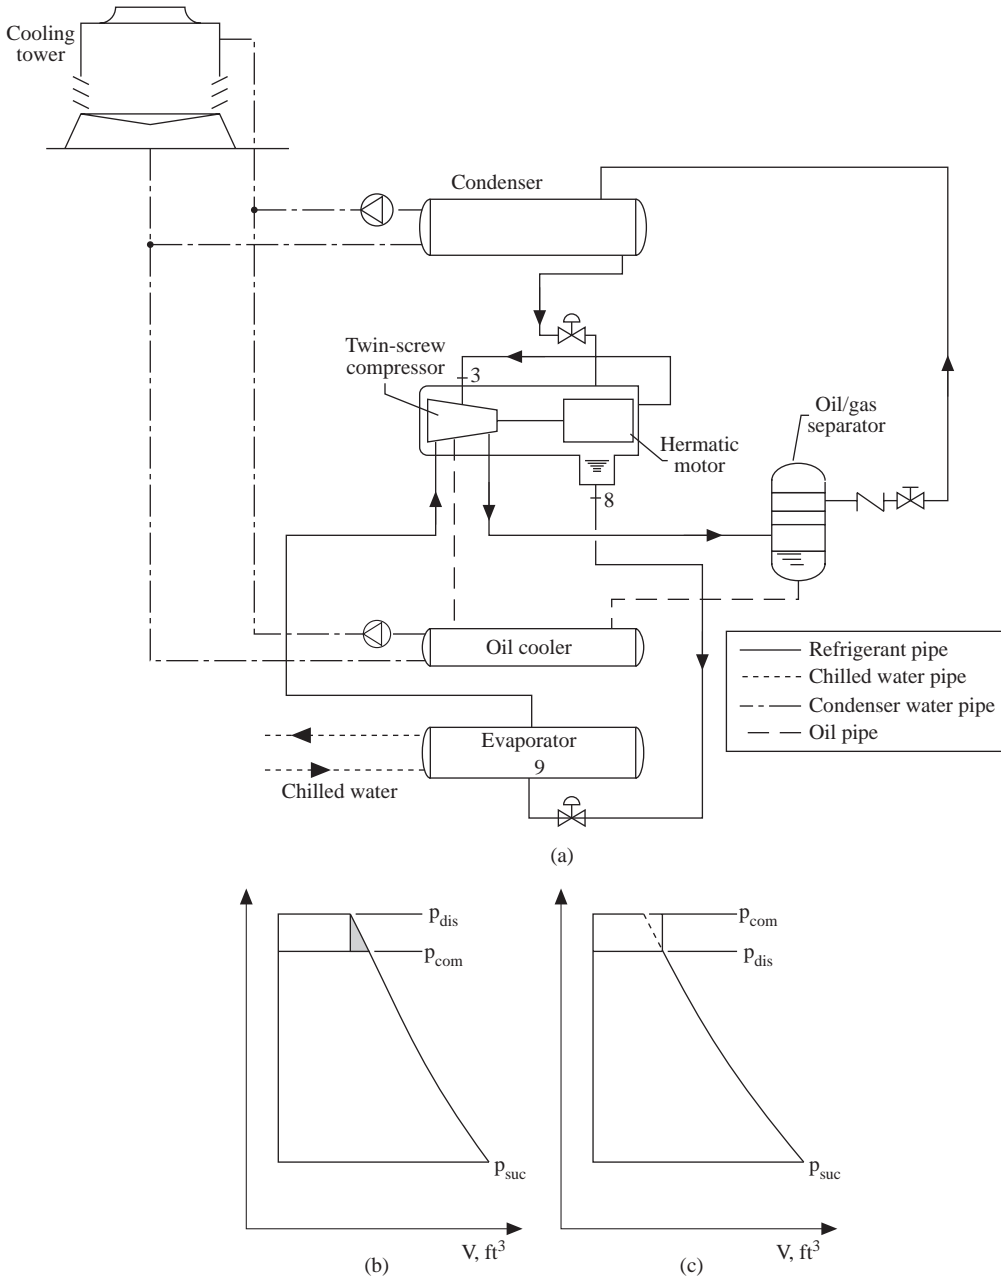

There are two types of twin-screw chiller: fixed and variable volume ratio. For a twin-screw chiller of *fixed volume ratio*, the isentropic efficiency  $\eta_{isen}$  becomes maximum when the system required compression ratio  $R_{s,com} \approx V_1$ . Here  $R_{s,com} = p_{con}/p_{ev}$ . If  $p_{dis} > p_{con}$ , overcompression occurs, as shown in Figure 9.11.4(b). The discharged hot gas reexpands to match the condensing pressure. If  $p_{dis} < p_{con}$ , undercompression occurs (Figure 9.11.4[c]). A volume of gas at condensing pressure reenters the trapped volume at the beginning of the discharge process. Both over- and undercompression cause a reduction of  $\eta_{isen}$ .

For a twin-screw chiller of *variable volume ratio*, there are two slides: a sliding valve is used for capacity control and a second slide. By moving the second slide back and forth, the radial discharge port can be relocated. This allows variation of suction and discharge pressure levels and still maintains maximum efficiency.

**Economizer.** The hermetic motor shell is connected to an intermediate point of the compression process and maintains an intermediate pressure  $p_i$  between  $p_{con}$  and  $p_{ev}$ . Liquid refrigerant at condensing pressure  $p_{con}$  is throttled to  $p_i$ , and a portion of the liquid is flashed into vapor. This causes a drop in the temperature of the remaining liquid refrigerant down to the saturated temperature corresponding to  $p_i$ . Although the compression in a twin-screw compressor is in continuous progression, the mixing of flashed gas with the compressed gas at the intermediate point actually divides the compression process into two stages. The resulting economizing effect is similar to that of a two-stage compound refrigeration system with a flash cooler: an increase of the refrigeration effect and a saving of the compression power from  $(p_{con} - p_{ev})$  to  $(p_{con} - p_i)$ .

**Oil Separation, Oil Cooling, and Oil Injection.** Oil entrained in the discharged hot gas enters an oil separator. In the separator, oil impinges on an internal perforated surface and is collected because of its inertia. Oil drops to an oil sump through perforation. It is then cooled by condenser water in a heat exchanger. A heater is often used to vaporize the liquid refrigerant in the oil sump to prevent dilution of the oil. Since the oil sump is on the high-pressure side of the refrigeration system, oil is forced to the rotor bearings and injected to the rotors for lubrication.

**FIGURE 9.11.4** A typical twin-screw chiller: (a) schematic diagram, (b) over-compression, and (c) under-compression.

Oil slugging is not a problem for twin-screw compressors. When suction vapor contains a small amount of liquid refrigerant that carries over from the oil separator, often called *wet suction*, it often has the benefit of scavenging the oil from the evaporator.

Twin-screw compressors are positive displacement compressors. They are critical in oil lubrication, sealing, and cooling. They are also more energy efficient than reciprocating compressors. Twin-screw chillers are gaining more applications, especially for ice-storage systems with cold air distribution.

## 9.12 Thermal Storage Systems

---

### Thermal Storage Systems and Off-Peak Air-Conditioning Systems

Many electric utilities in the United States have their *on-peak hours* between noon and 8 p.m. during summer weekdays, which include the peak-load hours of air-conditioning. Because the capital cost of a new power plant is so high, from \$1200 to \$4000 per kW, electric utilities tend to increase their power output by using customers' thermal energy storage (TES) systems, or simply thermal storage systems, which are much less expensive.

A *thermal storage system* as shown in Figure 9.12.1(a) may have the same refrigeration equipment, like chillers, additional storage tank(s), additional piping, pumps, and controls. The electric-driven compressors are operated during off-peak, partial-peak, and on-peak hours. *Off-peak hours* are often nighttime hours. *Partial-peak hours* are hours between on-peak and off-peak hours in a weekday's 24-hr day-and-night cycle. Chilled water or ice is stored in tanks to provide cooling for buildings during on-peak hours when higher electric demand and electric rates are effective. Although thermal storage systems operate during nighttime when outdoor dry and wet bulbs are lower, they are not necessarily energy saving due to lower evaporating temperature, additional pump power, and energy losses. Thermal storage systems significantly reduce the electric energy cost.

Utilities in the United States often use higher electric demand and rates as well as incentive bonus to encourage the shift of electric load from on-peak to off-peak hours by using thermal storage systems and others. Such a shift not only saves expensive capital cost, but also increases the use of base-load high-efficiency coal and nuclear plants instead of inefficient diesel and gas turbine plants.

The air-conditioning systems that operate during off-peak and partial-peak hours for thermal storage, or those that use mainly natural gas to provide cooling to avoid higher electric demand and rates during on-peak hours, are called *off-peak air-conditioning systems*. These systems include ice-storage and chilled-water storage systems, desiccant cooling systems, absorption systems, and gas engine chillers.

Absorption chillers and desiccant cooling systems are covered in other sections. Gas engine-driven reciprocating chillers are often a cogeneration plant with heat recovery from engine jacket and exhaust gas, and will not be covered here.

#### Full Storage and Partial Storage

Ice and chilled-water storage systems are the two most common thermal energy storage systems today. Knebel (1995) estimated that more than 4000 cool storage systems are operated in various commercial buildings.

The unit of stored thermal energy for cooling is ton-hour, or ton.hr. One *ton.hr* is the refrigeration capacity of one refrigeration ton during a 1-hr period, or 12,000 Btu.

In order to achieve minimum life-cycle cost, thermal storage systems could be either full storage or partial storage. For a *full-storage*, or *load shift*, thermal storage system, all refrigeration compressors cease to operate during on-peak hours. Building refrigeration loads are entirely offset by the chilled water or brine from the thermal storage system within an on-peak period. In a *partial storage*, or *load-leveling*, thermal storage system as shown in Figure 9.12.1(b) all or some refrigeration compressor(s) are operated during on-peak hours.

*Direct cooling* is the process in which refrigeration compressors produce refrigeration to cool the building directly. During a specific time interval, if the cost of direct cooling is lower than the stored energy, the operation of a thermal storage system is said to be in *chiller priority*. On the contrary, if the cost of direct cooling is higher than the cost of stored energy, the operation is said to be at *storage priority*.

The optimum size of a thermal storage system is mainly determined according to the utility's electric rate structure, especially a time-of-day structure whose electric rates are different between on-peak, partial-peak, and off-peak hours. Not only the design day's instantaneous building peak cooling load is important, but also an hour-by-hour cooling load profile of the design day is required for thermal storage design. A simple payback or a life-cycle cost analysis is usually necessary.

**FIGURE 9.12.1** A brine-coil ice-storage system: (a) schematic diagram, (b) partial-storage time schedule, (c) ice making, and (d) ice burning.

## Ice-Storage Systems

### System Characteristics

In an *ice-thermal-storage* system, or simply an *ice-storage* system, ice is stored in a tank or other containers to provide cooling for buildings in on-peak hours or on- and partial-peak hours. One pound of ice can store  $[(1 \times 144) + (55 - 35)] = 164$  Btu instead of  $(60 - 44) = 16$  Btu for chilled water storage. For the same cooling capacity, the storage volume of ice is only about 12% of chilled water. In addition,

an air-conditioning system using ice storage often adopts cold air distribution to supply conditioned air at a temperature typically at 44°F. Cold air distribution reduces the size of air-side equipment, ducts, and investment as well as fan energy use. It also improves the indoor air quality of the conditioned space. Since the late 1980s, ice storage has gained more applications than chilled water storage.

*Brine* is a coolant without freezing and flashing during normal operation. The freezing point of brine, which has a mass fraction of ethylene glycol of 25%, drops to 10°F, and a mass fraction of propylene glycol of 25% drops to 15°F. Glycol-water, when glycol is dissolved in water, is another coolant widely used in ice-storage systems. Ice crystals are formed in glycol-water when its temperature drops below its freezing point during normal operation.

In an ice-storage system, *ice making* or *charging* is a process in which compressors are operated to produce ice. *Ice burning*, or *discharging*, is a process in which ice is melted to cool the brine or glycol-water to offset refrigeration load.

*Brine-Coil Ice-Storage Systems.* Currently used ice-storage systems include brine-coil, ice-harvester, and ice-on-coil systems. According to Knebel (1995), the brine-coil ice-storage system is most widely used today because of its simplicity, flexibility, and reliability as well as using modular ice-storage tanks.

In a typical brine-coil ice-storage system, ice is charged in multiple modular factory-fabricated storage tanks as shown in [Figure 9.12.1\(a\)](#). In each storage tank, closely spaced polyethylene or plastic tubes are surrounded by water. Brine, a mixture of 25 to 30% of ethylene glycol by mass and 70 to 75% water, circulates inside the tubes at an entering temperature of 24°F during the ice-making process. The water surrounding the tubes freezes into ice up to a thickness of about 1/2 in. as shown in [Figure 9.12.1\(c\)](#). Brine leaves the storage tank at about 30°F. Water usually at atmospheric pressure is separated from brine by a plastic tube wall. Plastic tubes occupy about one tenth of the tank volume, and another one tenth remains empty for the expansion of ice. Multiple modular storage tanks are always connected in parallel.

During the ice-melting or -burning process, brine returns from the cooling coils in the air-handling units (AHUs) at a temperature of 46°F or higher. It melts the ice on the outer surface of the tubes and is thus cooled to a temperature of 34 to 36°F, as shown in [Figure 9.12.1\(d\)](#). Brine is then pumped to the AHUs to cool and dehumidify the air again.

*Case Study of a Brine-Coil Ice-Storage System.* In Tackett (1989), a brine-coil ice-storage system cools a 550,000-ft<sup>2</sup> office building near Dallas, TX, as shown in [Figure 9.12.1\(a\)](#). Ethylene glycol water is used as the brine. There are two centrifugal chillers, each of them having a refrigeration capacity of 568 tons when 34°F brine is produced with a power consumption of 0.77 kW/ton for direct cooling. The refrigeration capacity drops to 425 tons if 24°F brine leaves the chiller with a power consumption of 0.85 kW/ton. A demand-limited partial storage is used, as shown in [Figure 9.12.1\(b\)](#). During on-peak hours, ice is melted; at the same time one chiller is also operating. The system uses 90 brine-coil modular storage tanks with a full-charged ice-stored capacity of 7500 ton.hr.

For summer cooling, the weekdays' 24-hr day-and-night cycle is divided into three periods:

- Off peak lasts from 8 p.m. to AHU's start the next morning. Ice is charged at a maximum capacity of 650 tons. The chillers also provide 200 tons of direct cooling for refrigeration loads that operate 24 hr continuously.
- Direct cooling lasts from AHU's start until noon on weekdays. Chillers are operated for direct cooling. If required refrigeration load exceeds the chillers' capacity, some ice storage will be melted to supplement the direct cooling.
- On peak lasts from noon to 8 p.m. Ice is burning with one chiller in operation. During ice burning, water separates the tube and ice. Water has a much lower thermal conductivity (0.35 Btu/hr.ft.°F) than ice (1.3 Btu/hr.ft.°F). Therefore, the capacity of a brine-coil ice-storage system is dominated by the ice burning.

*Ice-Harvester Ice-Storage Systems.* In an *ice-harvester* system, glycol-water flows on the outside surface of the evaporator and forms ice sheets with a thickness of 0.25 to 0.40 in. within 20 to 30 min. Ice is harvested in the form of flakes when hot gas is flowing inside the tubes of the evaporator during a time interval of 20 to 30 sec. Ice flakes fall to the glycol-water in the storage tank below. The glycol-water at a temperature of 34°F is then supplied to the cooling coils in AHUs for conditioning. After cooling and dehumidifying the air, glycol-water returns to the storage tank at a temperature of 50 to 60°F and is again cooled to 34°F again.

Ice harvesting is an intermittent process. It has a cycle loss due to harvesting of about 15%. In addition, because of its operating complexity and maintenance, its applications are more suitable for large ice-storage systems.

*Ice-on-Coil Ice-Storage Systems.* In an *ice-on-coil* system, refrigerant is evaporated in the coils submerged in water in a storage tank. Ice of a thickness not exceeding 0.25 in. builds up on the outer surface of the coils. The remaining water in the storage tank is used for cooling in AHUs. Ice-on-coil systems need large amounts of refrigerant charge and are less flexible in operation. They are usually used in industrial applications.

*Ice-in-Containers Ice-Storage Systems.* Ice-in-containers ice-storage systems store ice in enclosed containers. Brine circulating over the containers produces the ice inside containers. Complexity in control of the ice inventory inside the containers limits the application of the ice-in-containers systems.

## Chilled-Water Storage Systems

### Basics

*Chilled-water storage* uses the same water chiller and a similar coolant distribution system, except for additional water storage tanks and corresponding piping, additional storage pumps, and controls. The larger the chilled-water storage system, the lower the installation cost per ton.hr storage capacity.

Various types of storage tanks had been used in chilled-water storage systems during the 1970s. A diaphragm tank uses a rubber diaphragm to separate the colder and warmer water. Baffles divide the tank into cells and compartments. Today, stratified tanks have become the most widely used chilled-water storage systems because of their simplicity, low cost, and negligible difference in loss of cooling capacity between stratified tanks and other types of storage tanks.

During the storage of chilled water, the loss in cooling capacity includes direct mixing, heat transfer between warmer return chilled water and colder stored chilled water, and also heat transfer between warmer ambient air and colder water inside the tank. An enthalpy-based easily measured index called *figure of merit (FOM)* is often used to indicate the loss in cooling capacity during chilled-water storage. FOM is defined as:

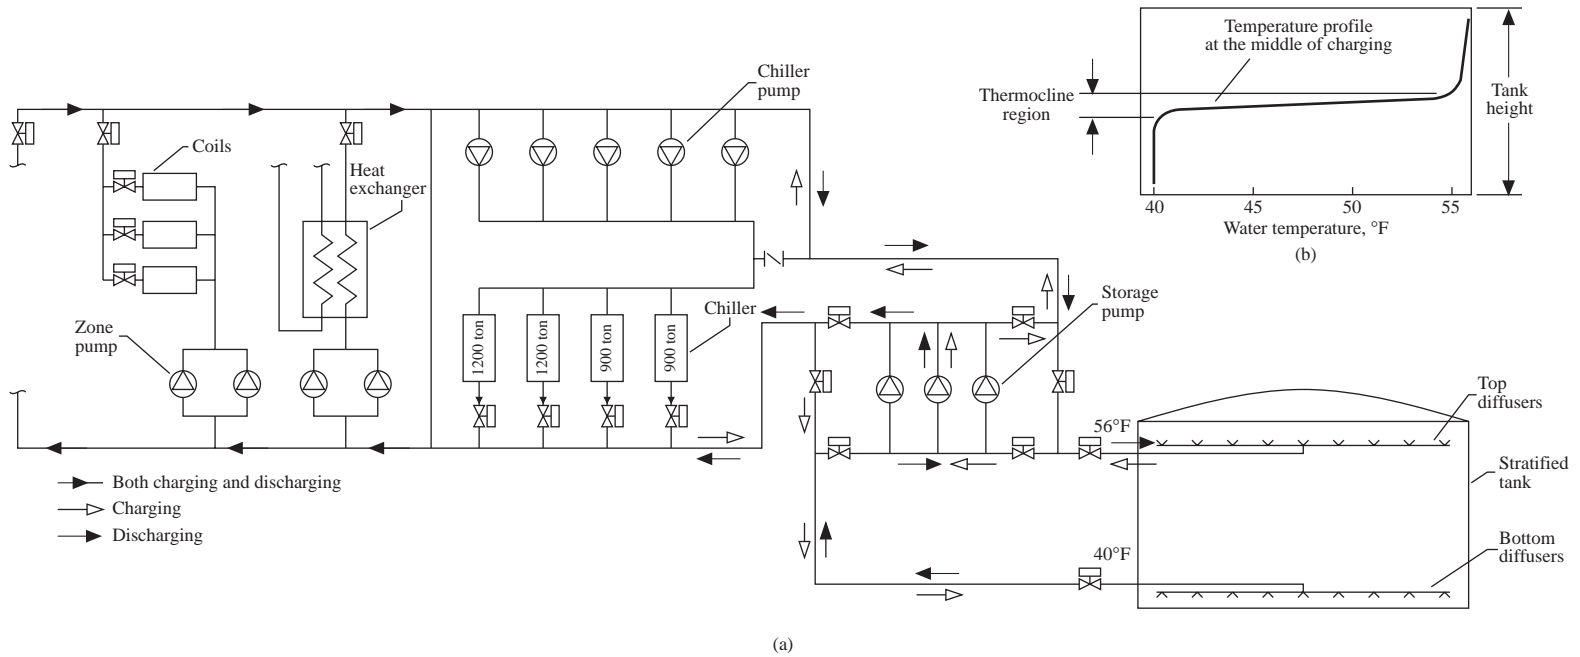

$$\text{FOM} = q_{\text{dis}}/q_{\text{ch}} \quad (9.12.1)$$

where  $q_{\text{dis}}$  = cooling capacity available in the discharge process, Btu/hr  
 $q_{\text{ch}}$  = theoretical cooling capacity available during charging process, Btu/hr

*Charging* is the process of filling the storage tank with colder chilled water from the chiller. At the same time, warmer return chilled water is extracted from the storage tank and pumped to the chiller for cooling.

*Discharging* is the process of discharging the colder stored chilled water from the storage tank to AHUs and terminals. Meanwhile, the warmer return chilled water from the AHUs and terminals fills the tank.

*Stratified Tanks.* *Stratified tanks* utilize the buoyancy of warmer return chilled water to separate it from the colder stored chilled water during charging and discharging, as shown in [Figure 9.12.2\(a\)](#). Colder stored chilled water is always charged and discharged from bottom diffusers, and the warmer return chilled water is introduced to and withdrawn from the top diffusers.

**FIGURE 9.12.2** A chilled-water storage system using stratified tanks: (a) schematic diagram of a chilled-water storage system and (b) thermocline at the middle of charging process.

Chilled-water storage tanks are usually vertical cylinders and often have a height-to-diameter ratio of 0.25:0.35. Steel is the most commonly used material for above-grade tanks, with a 2-in.-thick spray-on polyurethane foam, a vapor barrier, and a highly reflective coating. Concrete, sometimes precast, prestressed tanks are widely used for underground tanks.

A key factor to reduce loss in cooling capacity during chilled water storage is to reduce mixing of colder and warmer water streams at the inlet. If the velocity pressure of the inlet stream is less than the buoyancy pressure, the entering colder stored chilled water at the bottom of tank will stratify. Refer to Wang's handbook (1993) and Knebel (1995) for details.

A *thermocline* is a stratified region in a chilled-water storage tank of which there is a steep temperature gradient as shown in [Figure 9.12.2\(b\)](#). Water temperature often varies from 42°F to about 60°F. Thermocline separates the bottom colder stored chilled water from the top warmer return chilled water. The thinner the thermocline, the lower the mixing loss.

Diffusers and symmetrical connected piping are used to evenly distribute the incoming water streams with sufficient low velocity, usually lower than 0.9 ft/sec. Inlet stream from bottom diffusers should be downward and from the top diffusers should be upward or horizontal.

Field measurements indicate that stratified tanks have a FOM between 0.85 to 0.9.

## 9.13 Air System Basics

### Fan-Duct Systems

#### Flow Resistance

*Flow resistance* is a property of fluid flow which measures the characteristics of a flow passage resisting the fluid flow with a corresponding total pressure loss  $\Delta p$ , in in. WG, at a specific volume flow rate  $\dot{V}$ , in cfm:

$$\Delta p = R \dot{V}^2 \quad (9.13.1)$$

where  $R$  = flow resistance (in. WG/(cfm)<sup>2</sup>).

For a duct system that consists of several duct sections connected in series, its flow resistance  $R_s$ , in in. WG/(cfm)<sup>2</sup>, can be calculated as

$$R_s = R_1 + R_2 + \dots + R_n \quad (9.13.2)$$

where  $R_1, R_2, \dots, R_n$  = flow resistance of duct section 1, 2, ... n in the duct system (in. WG/(cfm)<sup>2</sup>).

For a duct system that consists of several duct sections connected in parallel, its flow resistance  $R_p$ , in in. WG/(cfm)<sup>2</sup>, is:

$$1/\sqrt{R_p} = 1/\sqrt{R_1} + 1/\sqrt{R_2} + \dots + 1/\sqrt{R_n} \quad (9.13.3)$$

#### Fan-Duct System

In a *fan-duct system*, a fan or several fans are connected to ductwork or ductwork and equipment. The volume flow and pressure loss characteristics of a duct system can be described by its performance curve, called *system curve*, and is described by  $\Delta p = R \dot{V}^2$ .

An *air system* or an air handling system is a kind of fan-duct system. In addition, an outdoor ventilation air system to supply outdoor ventilation air, an exhaust system to exhaust contaminated air, and a smoke control system to provide fire protection are all air systems, that is, fan-duct systems.

#### Primary, Secondary, and Transfer Air

Primary air is the conditioned air or makeup air. Secondary air is often the induced space air, plenum air, or recirculating air. Transfer air is the indoor air that moves to a conditioned space from an adjacent area.

#### System-Operating Point

A *system-operating point* indicates the operating condition of an air system or fan-duct system. Since the operating point of a fan must lie on the fan performance curve, and the operating point of a duct system on the system curve, the system operating point of an air system must be the intersection point  $P_s$  of the fan performance curve and system curve as shown in [Figure 9.13.1\(a\)](#).

#### Fan-Laws

For the same air system operated at speeds  $n_1$  and  $n_2$ , both in rpm, their relationship of  $\dot{V}$  volume flow rate, in cfm, system total pressure loss, in in. WG, and fan power input, in hp, can be expressed as

$$\begin{aligned} \dot{V}_2/\dot{V}_1 &= n_2/n_1 \\ \Delta p_{t2}/\Delta p_{t1} &= (n_2/n_1)^2 (\rho_2/\rho_1) \\ P_2/P_1 &= (n_2/n_1)^3 (\rho_2/\rho_1) \end{aligned} \quad (9.13.4)$$

where  $\rho$  = air density (lb/ft<sup>3</sup>). Subscripts 1 and 2 indicate the original and the changed operating conditions. For air systems that are geometrically and dynamically similar:

$$\begin{aligned}\dot{V}_2/\dot{V}_1 &= (D_2/D_1)^3 (n_2/n_1) \\ \Delta p_{t2}/\Delta p_{t1} &= (D_2/D_1)^2 (n_2/n_1)^2 (\rho_2/\rho_1) \\ P_2/P_1 &= (D_2/D_1)^5 (n_2/n_1)^3 (\rho_2/\rho_1)\end{aligned}\quad (9.13.5)$$

where  $D$  = diameter of the impeller (ft).

Geometrically similar means that two systems are similar in shape and construction. For two systems that are dynamically similar, they must be geometrically similar, and in addition, their velocity distribution or profile of fluid flow should also be similar. When fluid flows in the air systems are at high Reynolds number, such as  $Re > 10,000$ , their velocity profiles can be considered similar to each other.

## System Effect

The system effect  $\Delta p_{se}$ , in in. WG, of an air system is its additional total pressure loss caused by uneven or nonuniform velocity profile at the fan inlet, or at duct fittings after fan outlet, due to the actual inlet and outlet connections as compared with the total pressure loss of the fan test unit during laboratory ratings. The selected fan total pressure which includes the system effect  $\Delta p_{ts}$ , in in. WG, as shown in Figure 9.13.1(a), can be calculated as

$$\begin{aligned}\Delta p_{ts} &= \Delta p_{sy} + \Delta p_{se} = \Delta p_{sy} + \Delta p_{s,i} + \Delta p_{s,o} \\ &= \Delta p_{sy} + C_{s,i} (v_{fi}/4005)^2 + C_{s,o} (v_{fo}/4005)^2\end{aligned}\quad (9.13.6)$$

where  $\Delta p_{sy}$  = calculated total pressure loss of the air system, in WG

$\Delta p_{s,i}$ ,  $\Delta p_{s,o}$  = fan inlet and outlet system effect loss, in WG

$C_{s,i}$ ,  $C_{s,o}$  = local loss coefficient of inlet and outlet system effect, in WG

$v_{fi}$ ,  $v_{fo}$  = velocity at fan inlet (fan collar) and fan outlet, fpm

Both  $C_{s,i}$  and  $C_{s,o}$  are mainly affected by the length of connected duct between the duct fitting and fan inlet or outlet, by the configuration of the duct fitting, and by the air velocity at the inlet or outlet. Because  $v_{fi}$  and  $v_{fo}$  are often the maximum velocity of the air system, system effect should not be overlooked. According to AMCA Fan and Systems (1973), a square elbow (height to turning radius ratio  $R/H = 0.75$ ) connected to a fan inlet with a connected duct length of  $2 D_e$  (equivalent diameter) and  $v_{fi} = 3000$  fpm may have a 0.67 in. WG  $\Delta p_{i,o}$  loss. Refer to AMCA Fan and Systems (1973) or Wang's handbook (1993) for details.

## Modulation of Air Systems

Air systems can be classified into two categories according to their operating volume flow: constant volume and variable-air-volume systems. The volume flow rate of a *constant volume system* remains constant during all the operating time. Its supply temperature is raised during part load. For a *variable-air-volume (VAV) system*, its volume flow rate is reduced to match the reduction of space load at part-load operation. The system pressure loss of a VAV system can be divided into two parts: variable part  $\Delta p_{var}$  and fixed part  $\Delta p_{fix}$ , which is the set point of the duct static pressure control as shown in Figure 9.13.1(b) and (c). The *modulation curve* of a VAV air system its its operating curve, or the locus of system operating points when its volume flow rate is modulated at full- and part-load operation.

**FIGURE 9.13.1** Air system  $\dot{V}$ - $\Delta p_t$  performance: (a) system operating point and system effect, (b) modulation curve, and (c) damper, inlet vanes, and fan speed modulation.

The volume flow and system pressure loss of an air system can be modulated either by changing its fan characteristics or by varying its flow resistance of the duct system. Currently used types of modulation of volume flow rate of VAV air systems are

1. *Damper modulation* uses an air damper to vary the opening of the air flow passage and therefore its flow resistance.
2. *Inlet vanes modulation* varies the opening and the angle of inlet vanes at the centrifugal fan inlet and then gives different fan performance curves.
3. *Inlet cone modulation* varies the peripheral area of the fan impeller and therefore its performance curve.
4. *Blade pitch modulation* varies the blade angle of the axial fan and its performance curve.
5. *Fan speed modulation* using *adjustable frequency AC drives* varies the fan speed by supplying a variable-frequency and variable-voltage power source. There are three types of AC drives: adjustable voltage, adjustable current, and pulse width modulation (PWM). The PWM is universally applicable.

Damper modulation wastes energy. Inlet vanes are low in cost and are not so energy efficient compared with AC drives and inlet cones. Inlet cone is not expensive and is suitable for backward curved centrifugal fans. Blade pitch modulation is energy efficient and is mainly used for vane and tubular axial fans. AC drive is the most energy-efficient type of modulation; however, it is expensive and often considered cost effective for air systems using large centrifugal fans.

### Example 9.13.1

A multizone VAV system equipped with a centrifugal fan has the following characteristics:

$\dot{V}$ (cfm)	5,000	10,000	15,000	20,000	25,000
$\Delta p_t$ , in. WG	4.75	4.85	4.83	4.60	4.20
P, hp		17.0	18.6	20.5	21.2

At design condition, it has a volume flow rate of 22,500 cfm and a fan total pressure of 4.45 in. WG. The set point of duct static pressure control is 1.20 in. WG.

When this VAV system is modulated by inlet vanes to 50% of design flow, its fan performance curves show the following characteristics:

$\dot{V}$ (cfm)	5,000	10,000	11,250
$\Delta p_t$ , in. WG	3.6	2.5	2.1
P, hp		7.5	7.8

Determine the fan power input when damper, inlet vanes, or AC drive fan speed modulation is used. Assume that the fan total efficiency remains the same at design condition when the fan speed is reduced.

#### Solutions

- At 50% design flow, the volume flow of this VAV system is  $0.5 \times 22,500 = 11,250$  cfm. The flow resistance of the variable part of this VAV system is

$$R_{\text{var}} = \Delta p_{\text{va}} = R \dot{V}^2 = (4.45 - 1.20) / (22,500)^2 = 6.42 \times 10^{-9} \text{ in. WG}/(\text{cfm})^2$$

When damper modulation is used, the system operating point Q must be the intersection of the fan curve and the system curve that has a higher flow resistance and a  $\dot{V} = 11,250$  cfm. From Figure 9.13.1(c), at point Q, the fan power input is 17.0 hp.

- From the given information, when inlet vane modulation is used, the fan power input is 7.8 hp.
- The total pressure loss of the variable part of the VAV system at 50% volume flow is

$$\Delta p_{\text{var}} = R_{\text{var}} \dot{V}^2 = 6.42 \times 10^{-9} (11,250)^2 = 0.81 \text{ in. WG}$$

From Figure 9.13.1(c), since the fan power input at design condition is 21.2 hp, then its fan total efficiency is:

$$\eta_f = \dot{V} \Delta p_{\text{tf}} / (6356 P_f) = 22,500 \times 4.45 / (6356 \times 21.2) = 74.3\%$$

The fan power input at 50% design volume flow is:

$$P = \dot{V} \Delta p_{\text{tf}} / (6356 \eta_f) = 11,250(0.81 + 1.20) / (6356 \times 0.743) = 4.8 \text{ hp}$$

Damper modulation has a energy waste of  $(17 - 4.8) = 12.2$  hp

### Fan Combinations in Air-Handling Units and Packaged Units

Currently used fan combinations in air-handling units (AHUs) and packaged units (PUs) (except dual-duct VAV systems) are shown in Figure 9.13.2(a), (b), and (c):

**FIGURE 9.13.2** Fan combinations: (a) supply and exhaust fan, (b) supply and relief fan, and (c) supply and return fan.

### Supply and Exhaust Fan/Barometric Damper Combination

An air system equipped with a single supply fan and a constant-volume exhaust fan, or a supply fan and a barometric damper combination as shown in Figure 9.13.2(a), is often used in buildings where there is no return duct or the pressure loss of the return duct is low. An all-outdoor air economizer cycle is usually not adopted due to the extremely high space pressure. A barometric relief damper is often installed in or connected to the conditioned space to prevent excessively high space pressure. When the space-positive pressure exerted on the barometric damper is greater than the weight of its damper and/or a spring, the damper is opened and the excessive space pressure is relieved.

Consider a VAV rooftop packaged system using a supply fan and a constant-volume exhaust system to serve a typical floor in an office building. This air system has the following design parameters:

During minimum outdoor ventilation air *recirculating mode* at summer design volume flow and at 50% of design volume flow, the outdoor damper is at its minimum opening. The recirculating damper is fully opened. The outdoor air intake at the PU must be approximately equal to the exfiltration at the conditioned space due to the positive space pressure  $p_r$ , in in. WG. By using the iteration method, the calculated pressure characteristics and the corresponding volume flow rates are shown below:

Supply volume flow rate:		20,000 cfm
Total pressure loss:	Across the recirculating damper	0.1 in. WG
	Filter and coils	2.5 in. WG
	Supply main duct	0.85 in. WG
	Return system between point r and ru	0.2 in. WG
Effective leakage area on the building shell		3.35 ft <sup>2</sup>
Minimum outdoor ventilation air		3000 cfm
Space pressure at design flow		+0.05 in. WG

Point	o	m	r	ru
Design flow:				
$p_s$ in. WG	0	-0.20	+0.05	-0.15
$V$ , cfm	3,000	20,000	20,000	17,000
50% design:				
$p_s$ in. WG	0	-0.092	+0.0225	-0.052
$V$ , cfm	2,025	10,000	10,000	7,975

Here, o represents outdoor, m the mixing box, r the space, and ru the recirculating air inlet to the PU.

When the supply volume flow is reduced from the design volume flow to 50% of design flow during the recirculating mode, the total pressure in the mixing box increases from  $-0.20$  to  $-0.092$  in. WG and the outdoor air intake reduces from 3000 to 2025 cfm. Refer to Wang's (1993) *Handbook of Air Conditioning and Refrigeration* for details.

### Supply and Relief Fan Combination

Figure 9.13.2(b) shows the schematic diagrams of an air system of supply fan and relief fan combination. A relief fan is used to relieve undesirable high positive space pressure by extracting space air and relieving it to the outside atmosphere. A relief fan is always installed in the relief flow passage after the junction of return flow, relief flow, and recirculating flow passage, point ru. It is usually energized only when the air system is operated in air economizer mode. A relief fan is often an axial fan. Since the relief fan is not energized during recirculating mode operation, the volume flow and pressure characteristics of a supply fan and relief fan combination are the same as that in a single supply fan and barometric damper combination when they have the same design parameters.

During air economizer mode, the outdoor air damper(s) are fully opened and the recirculating damper closed. The space pressure  $p_r = +0.05$  in. WG is maintained by modulating the relief fan speed or relief damper opening. The pressure and volume flow characteristics of a supply and relief fan combination at design volume flow and 50% of design flow are as follows:

Point	o	m	r	ru
Design flow:				
$p_s$ in. WG	0	-0.20	+0.05	-0.15
$V$ , cfm	20,000	20,000	20,000	17,000
50% design:				
$p_s$ in. WG	0	-0.057	+0.05	+0.007
$V$ , cfm	10,000	10,000	10,000	7,000

### Supply Fan and Return Fan Combination

A return fan is always installed at the upstream of the junction of return, recirculating, and exhaust flow passage, point ru as shown in Figure 9.13.2(c). A supply and return fan combination has similar pressure and volume flow characteristics as that of a supply and relief fan combination, except a higher total

pressure at point ru. If the return fan is improperly selected and has an excessive fan total pressure, total pressure at point m may be positive. There will be no outdoor intake at the PU or AHU, and at the same time there will also be a negative space pressure and an infiltration to the space.

### Comparison of These Three Fan Combination Systems

A supply fan and barometric damper combination is simpler and less expensive. It is suitable for an air system which does not operate at air economizer mode and has a low pressure drop in the return system.

For those air systems whose pressure drop of return system is not exceeding 0.3 in. WG, or there is a considerable pressure drop in relief or exhaust flow passage, a supply and relief fan combination is recommended. For air systems whose return system has a pressure drop exceeding 0.6 in. WG, or those requiring a negative space pressure, a supply and return fan combination seems more appropriate.

### Year-Round Operation and Economizers

Consider a typical single-duct VAV reheat system to serve a typical floor whose indoor temperature is 75°F with a relative humidity of 50%, as shown in Figure 9.13.3(a). During summer, the off-coil temperature is 55°F. The year-round operation of this air system can be divided into four regions on the psychrometric chart, as shown in Figure 9.13.3(b):

- *Region I — Refrigeration/evaporative cooling.* In this region, the enthalpy of the outdoor air  $h_o$  is higher than the enthalpy of the recirculating air  $h_{ru}$ ,  $h_o > h_{ru}$ . It is more energy efficient to condition the mixture of recirculating air and minimum outdoor air.
- *Region II — Free cooling and refrigeration.* In this region,  $h_o \leq h_{ru}$ . It is more energy efficient and also provides better indoor air quality to extract 100% outdoor air.
- *Region III — Free cooling evaporative cooling, and refrigeration.* In this region, extract 100% outdoor air for free cooling because  $h_o \leq h_{ru}$ . Use evaporative cooling and refrigeration to cool and humidify if necessary.
- *Region IV — Winter heating.* Maintain a 55°F supply temperature by mixing the recirculating air with the outdoor air until the outdoor air is reduced to a minimum value. Provide heating if necessary.

An economizer is a device consisting of dampers and control that uses the free cooling capacity of either outdoor air or evaporatively cooled water from the cooling tower instead of mechanical refrigeration. An air economizer uses outdoor air for free cooling. There are two kinds of air economizers: enthalpy-based, in which the enthalpy of outdoor and recirculating air is compared, and temperature-based, in which temperature is compared. A water economizer uses evaporatively cooled water.

### Fan Energy Use

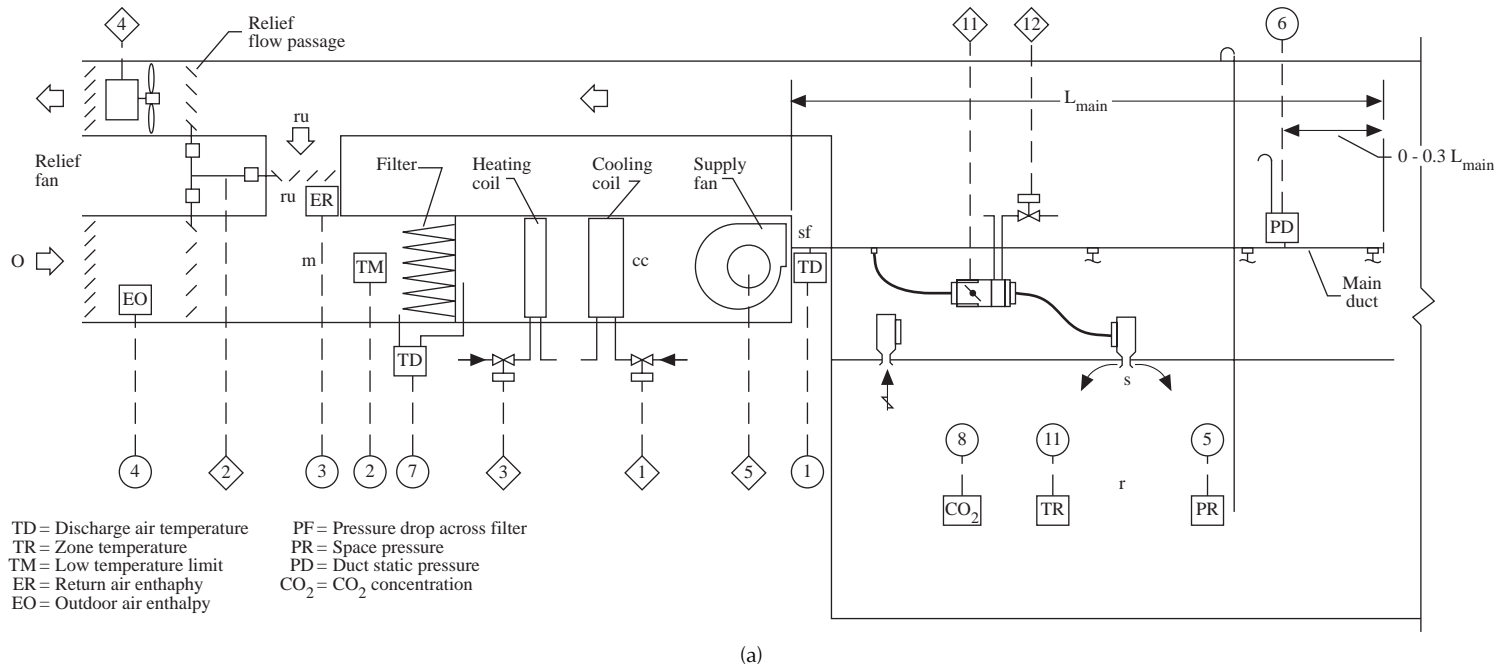

For an air system, fan energy use for each cfm of conditioned air supplied from the AHUs and PUs to the conditioned space within a certain time period, in W/cfm, can be calculated as

$$W/cfm = 0.1175\Delta p_{sy} / (\eta_f \eta_m) \quad (9.13.7)$$

where  $\Delta p_{sy}$  = mean system total pressure loss during a certain time period, in. WG  
 $\eta_f$  = fan total efficiency  
 $\eta_m$  = combined motor and drive (direct drive or belt drive) efficiency

For an air system using a separate outdoor ventilation system, its fan energy use, in W/cfm, is then calculated as

$$W/cfm = (1 + R_{o,s}) [0.1175\Delta p_{sy} / (\eta_f \eta_m)] \quad (9.13.8)$$

**FIGURE 9.13.3** Year-round operation, discharge air temperature, and duct static pressure control for a VAV reheat system: (a) control diagram, (b) year-round operation, and (c) discharge air temperature control output diagram.

FIGURE 9.13.3bc

where  $R_{o,s}$  = ratio of outdoor air volume flow rate to supply volume flow rate.

## Outdoor Ventilation Air Supply

### Basics

- An adequate amount of outdoor ventilation air supply is the key factor to provide acceptable indoor air quality (IAQ) for a conditioned space. Although an inadequate amount of outdoor ventilation air supply causes poor IAQ, an oversupply of outdoor ventilation air other than in an air economizer cycle is often a waste of energy.
- According to local codes and ANSI/ASHRAE Standard 62-1989, the minimum outdoor ventilation rate for each person must be provided at the outdoor air intake of AHU or PU, or by an outdoor air ventilation system. If the minimum outdoor ventilation air rate is reduced by using higher efficiency filters to remove air contaminants in the recirculating air, then indoor air contaminant concentration must be lower than the specified level in ANSI/ASHRAE Standard 62-1989.
- For a multizone air system, although the ratio of outdoor ventilation air rate to supply air volume flow rate required may be varied from zone to zone, the excessive outdoor air supply to a specified zone will increase the content of unused outdoor air in the recirculating air in AHU or PU. This helps to solve the problem in any zone that needs more outdoor air.
- Since the occupancy in many buildings is often variable and intermittent, a demand-based variable amount of outdoor ventilation air control should be used instead of time-based constant volume outdoor ventilation air control, except during the air economizer cycle.

- Carbon dioxide (CO<sub>2</sub>) is a gaseous body effluent. CO<sub>2</sub> is an indicator of representative odor and an indicator of adequate outdoor ventilation rate at specific outdoor and indoor air concentration in a control zone at steady state. For most of the comfort air-conditioning systems, it is suitable to use CO<sub>2</sub> as a key parameter to control the intake volume flow rate of outdoor ventilation air to maintain an indoor CO<sub>2</sub> concentration not exceeding 800 to 1000 ppm in a critical or representative zone. As mentioned in Section 9.5, Persily (1993) showed that the actual measured indoor daily maximum CO<sub>2</sub> concentration levels in five buildings were all within 400 to 820 ppm.

If a field survey finds that a specific indoor air contaminant exceeds a specified indoor concentration, then a gas sensor for this specific contaminant or a mixed gas sensor should be used to control this specific indoor concentration level.

*Types of Minimum Outdoor Ventilation Air Control.* There are four types of minimum outdoor ventilation air control that are currently used:

- Type I uses a CO<sub>2</sub> sensor or a mixed gas sensor and a DDC controller to control the volume flow rate of outdoor ventilation air for a separate outdoor ventilation air system on the demand-based principle.
- Type II uses a CO<sub>2</sub> or mixed gas sensor and a DDC controller to control the ratio of the openings between outdoor and recirculating dampers and, therefore, the volume flow rates of outdoor air and recirculating air in AHUs or PUs on the demand-based principle.
- Type III uses a flow sensor or a pressure sensor and a DDC controller to control the openings of outdoor and recirculating dampers to provide a nearly constant volume outdoor air intake in VAV AHUs or VAV PUs.
- Type IV adjusts the opening of the outdoor damper manually to provide a constant volume of outdoor air in constant-volume AHUs and PUs. If the outdoor intake is mounted on the external wall without a windshield, the volume flow of outdoor ventilation air intake will be affected by wind force and direction.

Type I is the best minimum outdoor ventilation air control for the air system. For a VAV system, it is expensive. Type II is a better choice. Type III is more complicated and may cause energy waste. Type IV has the same result as Type III and is mainly used in constant-volume systems.

Outdoor intake must be located in a position away from the influence of exhaust outlets. Fans, control dampers, and filters should be properly operated and maintained in order to provide a proper amount of outdoor ventilation air as well as an acceptable IAQ.

## 9.14 Absorption System

Absorption systems use heat energy to produce refrigeration as well as heating if it is required. Water is the refrigerant and aqueous lithium bromide (LiBr) is widely used as the carrier to absorb the refrigerant and provide a higher coefficient of performance.

The mixture of water and anhydrous LiBr is called *solution*. The composition of a solution is usually expressed by its mass fraction, or percentage of LiBr, often called *concentration*. When the water vapor has boiled off from the solution, it is called *concentration solution*. If the solution has absorbed the water vapor, it is called *diluted solution*.

Absorption systems can be divided into the following categories:

- *Absorption chillers* use heat energy to produce refrigeration.
- *Absorption chiller/heaters* use direct-fired heat input to provide cooling or heating separately.
- *Absorption heat pumps* extract heat energy from the evaporator, add to the heat input, and release them both to the hot water for heating.
- *Absorption heat transformers* raise the temperature of the waste heat source to a required level.

Most recently installed absorption chillers use direct-fired natural gas as the heat source in many locations in the United States where there are high electric demand and electric rate at on-peak hours. Absorption chillers also are free from CFC and HCFC. An energy cost analysis should be done to determine whether an electric chiller or a gas-fired absorption chiller is the suitable choice.

Absorption heat pumps have only limited applications in district heating. Most absorption heat transformers need industrial waste heat. Both of them will not be covered here.

### Double-Effect Direct-Fired Absorption Chillers

Figure 9.14.1(a) shows a double-effect direct-fired absorption chiller. *Double effect* means that there are two generators. *Direct fired* means that gas is directly fired at the generator instead of using steam or hot water. A single-effect absorption chiller using steam as the heat input to its single generator has a COP only from 0.7 to 0.8, whereas a double-effect direct-fired absorption chiller has a COP approximately equal to 1 and therefore is the most widely used absorption chiller in the United States for new and retrofit projects today. The refrigeration capacity of double-effect direct-fired absorption chillers varies from 100 to 1500 tons.

A double-effect direct-fired absorption chiller mainly consists of the following components and controls:

- **Evaporator** — An *evaporator* is comprised of a tube bundle, spray nozzles, a water trough, a refrigerant pump, and an outer shell. Chilled water flows inside the tubes. A refrigerant pump sprays the liquid refrigerant over the outer surface of the tube bundle for a higher rate of evaporation. A water trough is located at the bottom to maintain a water level for recirculation.
- **Absorber** — In an *absorber*, there are tube bundles in which cooling water flows inside the tubes. Solution is sprayed over the outer surface of the tube bundle to absorb the water vapor. A solution pump is used to pump the diluted solution to the heat exchanger and low-temperature generator.
- **Heat exchangers** — There are two heat exchangers: *low-temperature heat exchanger* in which the temperature of hot concentrated solution is lower, and *high-temperature heat exchanger* in which the temperature of hot concentrated solution is higher. In both heat exchangers, heat is transferred from the hot concentrated solution to the cold diluted solution. Shell-and-tube or plate-and-frame heat exchangers are most widely used for their higher effectiveness.
- **Generators** — *Generators* are also called *desorbers*. In the *direct-fired generator*, there are the fire tube, flue tube, vapor/liquid separator, and flue-gas economizer. Heat is supplied from the gas burner or other waste heat source. The *low-temperature generator* is often of the shell-and-tube type. The water vapor vaporized in the direct-fired generator is condensed inside the tubes. The

(a)

(b)

**FIGURE 9.14.1** A double-effect direct-fired reverse-parallel-flow absorption chiller: (a) schematic diagram (reprinted by permission from the Trane catalog) and (b) absorption cycle.

latent heat of condensation thus released is used to vaporize the dilute solution in the low-temperature generator.

- Condenser — A condenser is usually also of the shell-and-tube type. Cooling water from the absorber flows inside the tubes.
- Throttling devices — Orifices and valves are often used as throttling devices to reduce the pressure of refrigerant and solution to the required values.
- Air purge unit — Since the pressure inside the absorption chiller is below atmospheric pressure, air and other noncondensable gases will leak into it from the ambient air. An *air purge unit* is used to remove these noncondensable gases from the chiller. A typical air purge unit is comprised of a pickup tube, a purge chamber, a solution spray, cooling water tubes, a vacuum pump, a solenoid valve, and a manual shut-off valve.

When noncondensable gases leak into the system, they tend to migrate to the absorber where pressure is lowest. Noncondensable gases and water vapor are picked from the absorber through the pickup tube. Water vapor is absorbed by the solution spray and returned to the absorber through a liquid trap at the bottom of the purge chamber. Heat of absorption is removed by the cooling water inside the tubes. Noncondensable gases are then evacuated from the chamber periodically by a vacuum pump to the outdoor atmosphere.

Palladium cells are used to continuously remove a small amount of hydrogen that is produced due to corrosion. Corrosion inhibitors like lithium chromate are needed to protect the machine parts from the corrosive effect of the absorbent when air is present.

## Absorption Cycles, Parallel-, Series-, and Reverse-Parallel Flow

An *absorption cycle* shows the properties of the solution and its variation in concentrations, temperature, and pressure during absorbing, heat exchanging, and concentration processes on an equilibrium chart as shown in [Figure 9.14.1\(b\)](#). The ordinate of the equilibrium chart is the saturated temperature and pressure of water vapor, in °F and mm Hg abs. The abscissa is the temperature of the solution, in °F. Concentration lines are incline lines. At the bottom of the concentration lines, there is a *crystallization line* or *saturation line*. If the mass of fraction of LiBr in a solution which remains at constant temperature is higher than the saturated condition, that part of LiBr exceeding the saturation condition tends to form solid crystals.

Because there are two generators, the flow of solution from the absorber to generators can be in series flow, parallel flow, or reverse-parallel flow. In a series-flow system, the diluted solution from the absorber is first pumped to the direct-fired generator and then to the low-temperature generator. In a parallel-flow system, diluted solution is pumped to both direct-fired and low-temperature generators in parallel. In a reverse-parallel-flow system as shown in [Figure 9.14.1\(a\)](#), diluted solution is first pumped to the low-temperature generator. After that, the partly concentrated solution is then sent to the direct-fired generator as well as to the intermediate point 4 between high- and low-temperature heat exchangers in parallel. At point 4, partly concentrated solution mixes with concentrated solution from a direct-fired generator. A reverse-parallel-flow system is more energy efficient.

## Solution and Refrigerant Flow

In a typical double-effect direct-fired reverse-parallel-flow absorption chiller operated at design full load, water is usually evaporated at a temperature of 42°F and a saturated pressure of 6.8 mm Hg abs in the evaporator. Chilled water returns from the AHUs or fan coils at a temperature typically 54°F, cools, and leaves the evaporator at 44°F. A refrigeration effect is produced due to the vaporization of water vapor and the removal of latent heat of vaporization from the chilled water.

Water vapor in the evaporator is then extracted to the absorber due to its lower vapor pressure. It is absorbed by the concentrated LiBr solution at a pressure of about 5 mm Hg abs. After absorption, the solution is diluted to a concentration of 58.6% and its temperature increases to 95°F (point 1). Most of the heat of absorption and the sensible heat of the solution is removed by the cooling water inside the

tube bundle. Diluted solution is then pumped by a solution pump to the low-temperature generator through a low-temperature heat exchanger.

In the low-temperature generator, the dilute solution is partly concentrated to 60.3% at a solution temperature of 180°F (point 3). It then divides into two streams: one of them is pumped to the direct-fired generator through a high-temperature heat exchanger, and the other stream having a slightly greater mass flow rate is sent to the intermediate point 4. In the direct-fired generator, the concentrated solution leaves at a concentration of 66% and a solution temperature of 306°F (point 7).

The mixture of concentrated and partly concentrated solution at point 4 has a concentration of 63% and a temperature of 192°F. It enters the low-temperature heat exchanger. Its temperature drops to 121°F before entering the absorber (point 5).

In the direct-fired generator, water is boiled off at a pressure of about 390 mm Hg abs. The boiled-off water vapor flows through the submerged tube in the low-temperature generator. The release of latent heat of condensation causes the evaporation of water from the dilution solution at a vapor pressure of about 50 mm Hg abs. The boiled-off water vapor in the low-temperature generator flows to the condenser through the top passage and is condensed into liquid water at a temperature of about 99°F and a vapor pressure of 47.7 mm Hg abs. This condensed liquid water is combined with the condensed water from the submerged tube at the trough. Both of them return to the evaporator after its pressure is throttled by an orifice plate.

### Part-Load Operation and Capacity Control

During part-load operation, a double-effect direct-fired reverse-parallel-flow absorption chiller adjusts its capacity by reducing the heat input to the direct-fired generator through the burner. Lower heat input results at less water vapor boiled off from the solution in the generators. This causes the drop in solution concentration, the amount of water vapor extracted, the rate of evaporation, and the refrigeration capacity. Due to less water vapor being extracted, both evaporating pressure and temperature will rise. Since the amount of water vapor to be condensed is greater than that boiled off from the generators, both the condensing pressure and condensing temperature decrease.

### Coefficient of Performance (COP)

The COP of an absorption chiller can be calculated as

$$\text{COP} = 12,000/q_{1g} \quad (9.14.1)$$

where  $q_{1g}$  = heat input to the direct-fired generator per ton of refrigeration output (Btu/hr.ton).

### Safety Controls

Safety controls in an absorption chiller include the following:

- Crystallization controls are devices available to prevent crystallization and dissolve crystals. Absorption chillers are now designed to operate in a region away from the crystallization line. It is no longer a serious problem in newly developed absorption systems. One such device uses a bypass valve to permit refrigerant to flow to the concentration solution line when crystallization is detected. Condenser water temperature is controlled by using a three-way bypass valve to mix the recirculating water with the evaporated cooled water from the tower to avoid the sudden drop of the temperature of concentrated solution in the absorber.
- Low-temperature cut-out control shuts down the absorption chiller if the temperature of the refrigerant in the evaporator falls below a preset limit to protect the evaporator from freezing.
- Chilled and cooling water flow switches stop the absorption chiller when the mass flow rate of chilled water or the supply of cooling water falls below a preset value.
- A high-pressure relief valve is often installed on the shell of the direct-fired generator to prevent its pressure from exceeding a predetermined value.

- Monitoring of low and high pressure of gas supply and flame ignition are required for direct-fired burner(s).
- Interlocked controls between absorption chiller and chilled water pumps, cooling water pumps, and cooling tower fans are used to guarantee that they are in normal operation before the absorption chiller starts.

### **Absorption Chiller/Heater**

A double-effect direct-fired reverse-parallel-flow absorption chiller/heater has approximately the same system components, construction, and flow process as the absorption chiller. The cooling mode operation is the same as in an absorption chiller. During the heating mode of an absorption chiller/heater, its evaporator becomes the condenser and is used to condense the water vapor that has been boiled off from the direct-fired generator. At design condition, hot water is supplied at a temperature of 130 to 140°F. The condenser and the low-temperature generator are not in operation. (See [Figure 9.14.1](#).)

In order to increase the coefficient of performance of the absorption chiller, a triple-effect cycle with three condensers and three desorbers has been proposed and is under development. A triple-effect absorption chiller is predicted to have a coefficient of performance of around 1.5. Its initial cost is also considerably increased due to a greater number of condensers and desorbers.

## 9.15 Air-Conditioning Systems and Selection

---

### Basics in Classification

The purpose of classifying air-conditioning or HVAC&R systems is to distinguish one type from another so that an optimum air-conditioning system can be selected according to the requirements. Proper classification of air-conditioning systems also will provide a background for using knowledge-based expert systems to help the designer to select an air-conditioning system and its subsystems.

Since air system characteristics directly affect the space indoor environmental parameters and the indoor air quality, the characteristics of an air system should be clearly designated in the classification.

The system and equipment should be compatible with each other. Each system has its own characteristics which are significantly different from others.

### Individual Systems

As described in Section 9.1, air conditioning or HVAC&R systems can be classified as individual, space, packaged, and central systems.

Individual systems usually have no duct and are installed only in rooms that have external walls and external windows. Individual systems can again be subdivided into the following.

#### Room Air-Conditioner Systems

A room air conditioner is the sole factory-fabricated self-contained equipment used in the room air-conditioning system. It is often mounted on or under the window sill or on a window frame as shown in [Figure 9.1.1](#). A room air-conditioner consists mainly of an indoor coil, a small forward-curved centrifugal fan for indoor coil, a capillary tube, a low-efficiency dry and reusable filter, grilles, a thermostat or other controls located in the indoor compartment, and a rotary, scroll, or reciprocating compressor, an outdoor coil, and a propeller fan for the outdoor coil located in the outdoor compartment. There is an outdoor ventilation air intake opening and a manually operated damper on the casing that divides the indoor and outdoor compartments. Room air-conditioners have a cooling capacity between 1/2 to 2 tons.

The following are system characteristics of a room air-conditioner system:

*Room heat pump system* is a room air-conditioner plus a four-way reversing valve which provides both the summer cooling and winter heating.

Air system: single supply fan

Fan, motor, and drive combined efficiency: 25%

Fan energy use: 0.3 to 0.4 W/cfm

Fan speed: HI-LO 2-speed or HI-MED-LO 3-speed

Outdoor ventilation air system: type IV

Cooling system: DX system, air-cooled condenser

EER 7.5 to 9.5 Btu/hr.W

Evaporating temperature  $T_{ev}$  at design load: typically 45°F

Heating system: electric heating (if any)

Part-load: on-off of refrigeration compressor

Sound level: indoor NC 45 to 50

Maintenance: More maintenance work is required.

Summer and winter mode air-conditioning cycles of a room air-conditioning system are similar to that shown in [Figure 9.3.4](#).

All fan, motor, and drive combined efficiencies for various air-conditioning systems are from data in ASHRAE Standard 90.1-1989.

### Packaged Terminal Air-Conditioner (PTAC) Systems

A packaged terminal air-conditioner is the primary equipment in a PTAC system. A PTAC system is similar to a room air-conditioner system. Their main differences are

- A PTAC uses a wall sleeve and is intended to be mounted through the wall.
- Heating is available from hot water, steam, heat pump, electric heater, and sometimes even direct-fired gas heaters.

PTACs are available in cooling capacity between 1/2 to 1 1/2 tons and a heating capacity of 2500 to 35,000 Btu/hr.

### Space (Space-Conditioning) Systems

Most space conditioning air-conditioning systems cool, heat, and filtrate their recirculating space air above or in the conditioned space. Space conditioning systems often incorporate heat recovery by transferring the heat rejected from the interior zone to the perimeter zone through the condenser(s). Space systems often have a separate outdoor ventilation air system to supply the required outdoor ventilation air.

Space systems can be subdivided into four-pipe fan-coil systems and water-source heat pump systems.

### Four-Pipe Fan-Coil Systems

In a four-pipe fan-coil unit system, space recirculating air is cooled and heated at a fan coil by using four pipes: one chilled water supply, one hot water supply, one chilled water return, and one hot water return. Outdoor ventilation air is conditioned at a make-up AHU or primary AHU. It is then supplied to the fan coil where it mixes with the recirculating air, as shown in [Figure 9.15.1\(a\)](#), or is supplied to the conditioned space directly.

A *fan-coil unit* or a *fan coil* is a *terminal* as shown in [Figure 9.15.1\(b\)](#). Fan-coil units are available in standard sizes 02, 03, 04, 06, 08, 10, and 12 which correspond to 200 cfm, 400 cfm, and so on in volume flow.

The following are system characteristics of a four-pipe fan-coil system:

A *two-pipe fan-coil system* has a supply and a return pipe only. Because of the problems of changeover from chilled water to hot water and vice versa, its applications are limited.

A *water-cooling electric heating fan-coil system* uses chilled water for cooling and an electric heater for heating as shown in [Figure 9.1.2](#). This system is often used in a location that has a mild winter.

Air system:

Fan-coil, space air recirculating

Fan, motor, and drive combined efficiency: 25%

Fan speed: HI-LO 2-speed and HI-MED-LO 3-speed

External pressure for fan coil: 0.06 to 0.2 in. WG

System fan(s) energy use: 0.45 to 0.5 W/cfm

No return air and return air duct

Outdoor ventilation air system: type I

An exhaust system to exhaust part of the outdoor ventilation air

Cooling system: chilled water from centrifugal or screw chiller

Water-cooled chiller energy use: 0.4 to 0.65 kW/ton

Heating system: hot water from boiler, electric heater

Part load: control the flow rate of chilled and hot water supplied to the coil. Since air leaving coil temperature  $T_{cc}$  rises during summer mode part load, space relative humidity will be higher.

Sound level: indoor NC 40 to 45

Maintenance: higher maintenance cost

System fan(s) energy use: 0.45 to 0.55 W/cfm (includes all fans in the four-pipe fan-coil system)

**FIGURE 9.15.1** A four-pipe fan-coil system: (a) schematic diagram, (b) fan-coil unit, and (c) air-conditioning cycle.

An air-conditioning cycle for a four-pipe fan-coil system with outdoor ventilation air delivered to the suction side of the fan coil is shown in Figure 9.15.1(c). A part of the space cooling and dehumidifying load is usually taken care by the conditioned outdoor ventilation air from the make-up AHU. A double-bundle condenser is often adopted in a centrifugal chiller to incorporate heat recovery for providing winter heating.

**Water-Source Heat Pump Systems**

Water-source heat pumps (WSHPs) are the primary equipment in a water-source heat pump system as shown in Figure 9.15.2(a). A *water-source heat pump* usually consists of an air coil to cool and heat the air; a water coil to reject and extract heat from the condenser water; a forward-curved centrifugal fan; reciprocating, rotary, or scroll compressor(s); a short capillary tube; a reversing valve; controls; and an outer casing. WSHPs could be either a horizontal or vertical unit. WSHPs usually have cooling

**FIGURE 9.15.2** A water-source heat pump system: (a) vertical system and (b) system schematic diagram..

capacities between 1/2 to 26 tons. Small-capacity WSHPs of 3 tons or less without ducts are used in perimeter zones, whereas large-capacity WSHPs with ductwork are used only in interior zones.

In addition to the WSHPs, a WSHP system usually is also comprised of an evaporative cooler or cooling tower to cool the condenser water; a boiler to provide the supplementary heat for the condenser water if necessary; two circulating pumps, one of them being standby; and controls, as shown in Figure 9.15.2(b). A separate outdoor ventilation air system is required to supply outdoor air to the WSHP or directly to the space.

During hot weather, such as outdoor wet bulb at 78°F, all the WSHPs are operated in cooling mode. Condenser water leaves the evaporative cooler at a temperature typically 92°F and absorbs condensing heat rejected from the condensers — the water coils in WSHPs. Condenser water is then raised to 104°F and enters the evaporative cooler. In an evaporative cooler, condenser water is evaporatively cooled indirectly by atmospheric air, so that it would not foul the inner surface of water coils in WSHPs.

During moderate weather, the WSHPs serving the shady side of a building may be in heating mode, and while serving the sunny side of the building and the interior space in cooling mode. During cold weather, most of the WSHPs serving perimeter zones are in heating mode, while serving interior spaces are in cooling mode except morning warm-up. Cooling WSHPs reject heat to the condenser water loop; meanwhile heating WSHPs absorb heat from the condenser water loop. The condenser water is usually maintained at 60 to 90°F. If its temperature rises above 90°F, the evaporative cooler is energized. If it drops below 60°F, the boiler or electric heater is energized. A WSHP system itself is a combination of WSHP and a heat recovery system to transfer the heat from the interior space and sunny side of the building to the perimeter zone and shady side of building for heating in winter, spring, and fall.

System characteristics of air, cooling, and heating in a WSHP system are similar to a room conditioner heat pump system. In addition:

- Outdoor ventilating air system: type I and IV
- Water system: two-pipe, close circuit
- Centrifugal water circulating pump
- Water storage tank is optional

To prevent freezing in locations where outdoor temperature may drop below 32°F, isolate the outdoor portion of the water loop, outdoor evaporative cooler, and the pipe work from the indoor portion by using a plate-and-frame heat exchanger. Add ethylene or propylene glycol to the outdoor water loop for freezing protection.

There is another space system called a panel heating and cooling system. Because of its higher installation cost and dehumidification must be performed in the separate ventilation systems, its applications are very limited.

A space conditioning system has the benefit of a separate demand-based outdoor ventilation air system. A WSHP system incorporates heat recovery automatically. However, its indoor sound level is higher; only a low-efficiency air filter is used for recirculating air, and more space maintenance is required than central and packaged systems. Because of the increase of the minimum outdoor ventilation air rate to 15 cfm/person recently, it may gain more applications in the future.

## Packaged Systems

In packaged systems, air is cooled directly by a DX coil and heated by direct-fired gas furnace or electric heater in a packaged unit (PU) instead of chilled and hot water from a central plant in a central system. Packaged systems are different from space conditioning systems since variable-air-volume supply and air economizer could be features in a packaged system. Packaged systems are often used to serve two or more rooms with supply and return ducts instead of serving individual rooms only in an individual system.

As mentioned in Section 9.7, packaged units are divided according to their locations into rooftop, split, or indoor units. Based on their operating characteristics, packaged systems can be subdivided into the following systems:

### Single-Zone Constant-Volume (CV) Packaged Systems

Although a single-zone CV packaged system may have duct supplies to and returns from two or more rooms, there is only a single zone sensor located in the representative room or space. A CV system has a constant supply volume flow rate during operation except the undesirable reduction of volume flow due to the increase of pressure drop across the filter.

A single-zone CV packaged system consists mainly of a centrifugal fan, a DX coil, a direct-fired gas furnace or an electric heater, a low or medium efficiency filter, mixing box, dampers, DDC controls, and an outer casing. A relief or a return fan is equipped for larger systems.

A single-zone CV packaged system serving a church is shown in [Figure 9.1.3](#). This system operates on basic air-conditioning cycles as shown in [Figure 9.3.4](#) during cooling and heating modes.

The system characteristics of a single-zone CV packaged system are

Air system: single supply fan, a relief or return fan for a large system

Fan, motor, and drive combined efficiency: 40 to 45%

Fan total pressure: 1.5 to 3 in. WG

Fan(s) energy use: 0.45 to 0.8 W/cfm

Outdoor ventilation air system: type IV and II

Enthalpy or temperature air economizer

Cooling systems: DX system, air cooled

Compressor: reciprocating or scroll

EER: 8.9 to 10.0 Btu/hr.W

Heating system: direct-fired gas furnace, air-source heat pump, or electric heating

Part load: on-off or step control of the compressor capacity, DX-coil effective area, and the gas flow to the burner

Sound level: indoor NC 35 to 45

Maintenance: higher maintenance cost than central systems

Single-zone, CV packaged systems are widely used in residences, small retail stores, and other commercial buildings.

### Constant-Volume Zone-Reheat Packaged Systems

System construction and system characteristics of a CV zone-reheat system are similar to the single-zone CV packaged systems except:

1. It serves multizones and has a sensor and a DDC controller for each zone.
2. There is a reheating coil or electric heater in the branch duct for each zone.

A CV zone-reheat packaged system cools and heats simultaneously and therefore wastes energy. It is usually used for the manufacturing process and space needs control of temperature and humidity simultaneously.

### Variable-Air-Volume Packaged Systems

A variable-air-volume (VAV) system varies its volume flow rate to match the reduction of space load at part load. A VAV packaged system, also called a *VAV cooling packaged system*, is a multizone system and uses a VAV box in each zone to control the zone temperature at part load during summer cooling mode operation, as shown in [Figure 9.15.3\(a\)](#).

A *VAV box* is a terminal in which the supply volume flow rate of the conditioned supply air is modulated by varying the opening of the air passage by means of a single blade damper, as shown in [Figure 9.15.3\(b\)](#), or a moving disc against a cone-shaped casing.

The following are the system characteristics of a VAV packaged system:

*Single-zone VAV packaged system* which serves a single zone without VAV boxes. A DDC controller modulates the position of the inlet vanes or the fan speed according to the signal of the space temperature sensor.

Air system: a supply/relief fan or supply/return fan combination. Space pressurization control by a relief/return fan

Fan, motor, and drive combined efficiency: 45%

Supply fan total pressure: 3.75 to 4.5 in. WG

Fan(s) energy use at design condition: 1 to 1.25 W/cfm

VAV box minimum setting: 30% of peak supply volume flow

Outdoor ventilation air system: type II and III

Economizer: enthalpy air economizer or water economizer

Cooling system: DX coil, air-, water-, or evaporative-cooled condenser

Compressor: reciprocating, scroll, and screw

EER: 8.9 to 12 Btu/hr.W

Capacity: 20 to 100 tons

Part load: zone volume flow modulation by VAV box; step control of compressor capacity; modulation of gas flow to burner; and discharge air temperature reset

Smoke control: exhausts smoke on the fire floor, and supplies air and pressurizes the floors immediately above or below the fire floor

Diagnostics: a diagnostic module displays the status and readings of various switches, dampers, sensors, etc. and the operative problems by means of expert system

Maintenance: higher than central system

Sound level: indoor NC 30 to 45

Heating system characteristics as well as the air-conditioning cycles are similar as that in a single-zone CV packaged system.

### VAV Reheat Packaged Systems

A VAV reheat packaged system has its system construction and characteristics similar to that in a VAV packaged system except in each VAV box there is an additional reheating coil. Such a VAV box is called

**FIGURE 9.15.3** A variable-air-volume (VAV) package system: (a) schematic diagram, (b) VAV box, (c) reheating box, (d) parallel-flow fan-powered VAV box.

a *reheating VAV box*, as shown in [Figure 9.15.2\(a\)](#) and [9.15.3\(c\)](#). VAV reheat packaged systems are used to serve perimeter zones where winter heating is required.

**Fan-Powered VAV Packaged Systems**

A fan-powered VAV packaged system is similar to that of a VAV packaged system except *fan-powered VAV boxes* as shown in [Figure 9.15.3\(d\)](#) are used instead of VAV boxes.

There are two types of fan-powered VAV boxes: parallel-flow and series-flow boxes. In a *parallel-flow* fan-powered box, the plenum air flow induced by the fan is parallel with the cold primary air flow through the VAV box. These two air streams are then combined and mixed together. In a *series-flow* box, cold primarily from the VAV box is mixed with the induced plenum air and then flows through the small fan. The parallel-flow fan-powered VAV box is more widely used.

**FIGURE 9.15.3d**

In a fan-powered VAV box, volume flow dropping to minimum setting, extracting of ceiling plenum air, and energizing of reheating coil will actuate in sequence to maintain the space temperature during part-load/heating mode operation. A fan-powered VAV box can also mix the cold primary air from cold air distribution with the ceiling plenum air and provides greater space air movements during minimum space load.

Packaged systems are lower in installation cost and occupy less space than central systems. During the past two decades, DDC-controlled packaged systems have evolved into sophisticated equipment and provide many features that only a built-up central system could provide before.

## Central Systems

Central systems use chilled and hot water that comes from the central plant to cool and heat the air in the air-handling units (AHUs). Central systems are built-up systems. The most clean, most quiet thermal-storage systems, and the systems which offer the most sophisticated features, are always central systems. Central systems can be subdivided into the following.

### Single-Zone Constant-Volume Central Systems

A single-zone CV central system uses a single controller to control the flow of chilled water, hot water, or the opening of dampers to maintain a predetermined indoor temperature, relative humidity, or air contaminants. They are often used in manufacturing factories. The system characteristics of a single-zone CV central system are

*Single-zone CV air washer central system* uses air washer to control both space relative humidity and temperature. This system is widely used in textile mills. The reason to use constant volume is to dilute the fiber dusts produced during manufacturing. A rotary filter is often used for high dust-collecting capacity.

Air system: supply and return fan combination

Fan, motor, and drive combined efficiency: 45 to 50%

Outdoor ventilation air system: type II and IV

Economizer: air or water economizer

Smoke control: exhaust smoke on the fire floor, and pressurize adjacent floor(s) or area

Cooling system: centrifugal or screw chiller, water-cooled condenser

Cooling energy use: 0.4 to 0.65 kW/ton

Heating system: hot water from boiler or from heat recovery system

- Part load: modulate the water mass flow to cooling and heating coils in AHUs, and discharge air temperature reset
- Sound level: indoor NC 30 to 45. Silencers are used both in supply and return air systems if they are required
- Maintenance: in central plant and fan rooms, lower maintenance cost

### Single-Zone CV Clean Room Systems

This is the central system which controls the air cleanliness, temperature, and relative humidity in Class 1, 10, 100, 1000, and 10,000 clean rooms for electronic, pharmaceutical, and precision manufacturing and other industries. [Figure 9.15.4\(a\)](#) shows a schematic diagram of this system. The recirculating air unit (RAU) uses prefilter, HEPA filters, and a water cooling coil to control the space air cleanliness and required space temperature, whereas a make-up air unit (MAU) supplies conditioned outdoor air, always within narrow dew point limits to the RAU at any outside climate, as shown in [Figure 9.15.4\(b\)](#). A unidirectional air flow of 90 fpm is maintained at the working area. For details, refer to *ASHRAE Handbook 1991 HVAC Applications* and Wang's *Handbook of Air Conditioning and Refrigeration*.

### CV Zone-Reheat Central Systems

These systems have their system construction and characteristics similar to that for a single-zone CV central system, except they serve multizone spaces and there is a reheating coil, hot water, or electric heating in each zone. CV zone-reheat central systems are often used for health care facilities and in industrial applications.

### VAV Central Systems

A VAV central system is used to serve multizone space and is also called *VAV cooling central system*. Its schematic diagram is similar to that of a VAV packaged system ([Figure 9.15.3](#)) except air will be cooled or heated by water cooling or heating coils in the AHUs. The same VAV box shown in [Figure 9.15.3\(b\)](#) will be used in a VAV central system. The system characteristics of VAV central systems are as follows:

*Single-zone VAV central system* differs from a VAV central system only because it serves a single zone, and therefore there is no VAV box in the branch ducts. Supply volume flow is modulated by inlet vanes and AC inverter.

Air system: supply and relief/return fan combination

Fan, motor, and drive combined efficiency for airfoil centrifugal fan with AC inverter fan speed modulation: 55%

Fan(s) energy use: 0.9 to 1.2 W/cfm

VAV box: minimum setting 30% of peak supply volume flow

Outdoor ventilation air system: type I, II, and III

Cooling system: centrifugal, screw, and reciprocating chillers, water-cooled condenser, with energy use 0.4 to 0.65 kW/ton; or sometimes absorption chiller

Heating system: hot water from boiler or electric heating at the terminals

Economizer: air and water economizer

Part load: zone volume flow modulation, discharge air temperature reset, and chilled water temperature reset

Smoke control: exhausts smoke from the fire floor and pressurizes the immediate floors above and below

Sound level: indoor NC 20 to 40. Silencers are often used both in supply and return systems.

Maintenance: less space maintenance

VAV central systems are widely used for interior zone in buildings.

FIGURE 9.15.4 A single-zone CV clean room system: (a) schematic diagram and (b) air-conditioning cycle.

### VAV Reheat Central Systems

A VAV reheat system is similar in system construction and characteristics to that in a VAV central system except that reheating boxes are used instead of VAV boxes in a VAV central system.

### Fan-Powered VAV Central Systems

A fan-powered VAV central system is similar in system construction and characteristics to that in a VAV central system except that fan-powered VAV boxes are used instead of VAV boxes.

### Dual-Duct VAV Central Systems

A dual-duct VAV system uses a warm air duct and a cold air duct to supply both warm and cold air to each zone in a multizone space, as shown in [Figure 9.15.5\(a\)](#). Warm and cold air are first mixed in a mixing VAV box, and are then supplied to the conditioned space. Warm air duct is only used for perimeter zones.

A *mixing VAV box* consists of two equal air passages, one for warm air and one for cold air, arranged in parallel. Each of them has a single blade damper and its volume flow rate is modulated. Warm and cold air are then combined, mixed, and supplied to the space.

A dual-duct VAV system is usually either a single supply fan and a relief/return fan combination, or a warm air supply fan, a cold air supply fan, and a relief/return fan. A separate warm air fan and cold air supply fan are beneficial in discharge air temperature reset and fan energy use.

During summer cooling mode operation, the mixture of recirculating air and outdoor air is used as the warm air supply. The heating coil is not energized. During winter heating mode operation, mixture of outdoor and recirculating air or 100% outdoor air is used as the cold air supply; the cooling coil is not energized.

Because there is often air leakage at the dampers in the mixing VAV box, more cold air supply is needed to compensate for the leaked warm air or leaked cold air.

Other system characteristics of a dual-duct VAV central system are similar to a VAV central system.

### Dual-Duct CV Central System

This is another version of a dual-duct VAV central system and is similar in construction to a dual-duct VAV system, except that a mixing box is used instead of a mixing VAV box. The supply volume flow rate from a mixing box is nearly constant. Dual-duct CV central systems have only limited applications, like health care facilities, etc.

An ice- or chilled-water storage system is always a central system plus a thermal storage system. The thermal storage system does not influence the system characteristics of the air distribution, and air cooling and heating — except for a greater head lift for a refrigeration compressor — is needed for ice-storage systems. Therefore, the following central systems should be added:

- VAV ice-storage or chilled-water systems
- VAV reheat ice-storage or chilled-water storage systems
- Fan-powered VAV ice-storage systems

Some of the air-conditioning systems are not listed because they are not effective or are a waste of energy, and therefore rarely used in new and retrofit projects such as:

- High-velocity induction space conditioning systems which need a higher pressure drop primary air to induce recirculating air in the induction unit and use more energy than fan-coil systems
- Multizone central systems which mix warm and cool air at the fan room and use a supply duct from fan room to each control zone
- Air skin central systems which use a warm air heating system to offset transmission loss in the perimeter zone and overlook the effect of the solar radiation from variation building orientations

In the future, there will be newly developed systems added to this classification list.

## Air-Conditioning System Selection

As described in Section 9.1, the goal of an air-conditioning or HVAC&R system is to provide a healthy, comfortable, manufacturable indoor environment at acceptable indoor air quality, keeping the system

FIGURE 9.15.5 A dual-duct VAV central system: (a) schematic diagram.

**FIGURE 9.15.5** A dual-duct VAV central system: (b) mixing VAV box and (c) volume flow-operating mode diagram.

energy efficient. Various occupancies have their own requirements for their indoor environment. The basic considerations to select an air-conditioning system include:

1. The selection of an air-conditioning system must satisfy the required space temperature, relative humidity, air cleanliness, sound level, and pressurization. For a Class 100 clean room, a single-zone CV clean room system is always selected. A four-pipe fan-coil space conditioning system is usually considered suitable for guest rooms in hotels for operative convenience, better privacy, and a guaranteed outdoor ventilation air system. A concert hall needs a very quiet single-zone VAV central system for its main hall and balcony.
2. The size of the project has a considerable influence on the selection. For a small-size residential air-conditioning system, a single-zone constant-volume packaged system is often the first choice.
3. Energy-efficient measures are specified by local codes. Comparison of alternatives by annual energy-use computer programs for medium and large projects is often necessary. Selection of energy source includes electricity or gas, and also using electrical energy at off-peak hours, like thermal storage systems is important to achieve minimum energy cost.

For a building whose sound level requirement is not critical and conditioned space is comprised of both perimeter and interior zones, a WSHP system incorporating heat recovery is especially suitable for energy saving.

4. First cost or investment is another critical factor that often determines the selection.
5. Selection of an air-conditioning system is the result of synthetical assessment. It is difficult to combine the effect of comfort, reliability, safety, and cost. Experience and detailed computer program comparisons are both important.

The selection procedure usually begins whether an individual, space conditioning, packaged, central system, or CV, VAV, VAV reheat, fan-powered VAV, dual-duct VAV, or thermal storage system is selected. Then the air, refrigeration, heating, and control subsystems will be determined. After that, choose the option, the feature, the construction, etc. in each subsystem.

## Comparison of Various Systems

The sequential order of system performance — excellent, very good, good, satisfactory — regarding temperature and relative humidity control (T&HC), outdoor ventilation air (OA), sound level, energy use, first cost, and maintenance for individual, space conditioning (SC), packaged, and central systems is as follows:

	<b>Excellent (low or less)</b>	<b>Very good</b>	<b>Good</b>	<b>Satisfactory</b>
T&HC	Central	Packaged	Space	Individual
IAQ	Space	Central	Packaged	Individual
Sound	Central	Packaged	Space	Individual
Energy use	Individual	Space	Packaged	Central
First cost	Individual	Packaged	Space	Central
Maintenance	Central	Packaged	Space	Individual

Among the packaged and central systems, VAV cooling systems are used only for interior zones. VAV reheat, fan-powered VAV, and dual-duct VAV central systems are all for perimeter zones. VAV reheat systems are simple and effective, but have a certain degree of simultaneous cooling and heating when their volume flow has been reduced to minimum setting. Fan-powered VAV systems have the function of mixing cold primary air with ceiling plenum air. They are widely used in ice-storage systems with cold air distribution. Fan-powered VAV is also helpful to create a greater air movement at minimum cold primary air flow. Dual-duct VAV systems are effective and more flexible in operation. They are also more complicated and expensive.

## Subsystems

### Air Systems

The economical size of an air system is often 10,000 to 25,000 cfm. A very large air system always has higher duct pressure loss and is more difficult to balance. For highrise buildings of four stories and higher, floor-by-floor AHU(s) or PU(s) (one or more AHU or PU per floor) are often adopted. Such an arrangement is beneficial for the balance of supply and return volume flow in VAV systems and also for fire protection. A fan-powered VAV system using a riser to supply less cold primary to the fan-powered VAV box at various floors may have a larger air system. Its risers can be used as supply and exhaust ducts for a smoke-control system during a building fire.

In air systems, constant-volume systems are widely used in small systems or to dilute air contaminants in health care facilities and manufacturing applications. VAV systems save fan energy and have better operating characteristics. They are widely used in commercial buildings and in many factories.

### Refrigeration Systems

For comfort air-conditioning systems, the amounts of required cooling capacity and energy saving are dominant factors in the selection of the refrigeration system. For packaged systems having cooling capacity less than 100 tons, reciprocating and scroll vapor compression systems with air-cooled condensers are most widely used. Evaporative-cooled condensers are available in many packaged units manufactured for their lower energy use. Scroll compressors are gradually replacing the reciprocating compressors for their simple construction and energy saving. For chillers of cooling capacity of 100 tons and greater, centrifugal chillers are still most widely used for effective operation, reliability, and energy efficiency. Screw chillers have become more popular in many applications, especially for ice-storage systems.

### Heating Systems

For locations where there is a cold and long winter, a perimeter baseboard hot water heating system or dual-duct VAV systems are often a suitable choice. For perimeter zones in locations where winter is mild, winter heating is often provided by using warm air supply from AHU or PU from terminals with electric or hot water heaters. Direct-fired furnace warm air supply may be used for morning warm-up. For interior or conditioned zones, a cold air supply during occupied periods in winter and a warm air supply from the PUs or AHUs during morning warm-up period is often used.

## Control Systems

Today, DDC microprocessor-based control with open data communication protocol is often the choice for medium- and large-size HVAC&R projects. For each of the air, cooling, and heating systems, carefully select the required generic and specific control systems. If a simple control system and a more complicated control system can provide the same required results, the simple one is always the choice.

## Energy Conservation Recommendations

1. Turn off electric lights, personal computers, and office appliances when they are not needed. Shut down AHUs, PUs, fan coils, VAV boxes, compressors, fans, and pumps when the space or zone they serve is not occupied or working.
2. Provide optimum start and stop for the AHUs and PUs and terminals daily.
3. Temperature set point should be at its optimum value. For comfort systems, provide a dead band between summer and winter mode operation. Temperature of discharged air from the AHU or PU and chilled water leaving the chiller should be reset according to space or outdoor temperature or the system load.
4. Reduce air leakages from ducts and dampers. Reduce the number of duct fittings and pipe fittings and their pressure loss along the design path if this does not affect the effectiveness of the duct system. The maximum design velocity in ducts for comfort systems should not exceed 3000 fpm, except that a still higher velocity is extremely necessary.
5. Adopt first the energy-efficient cooling methods: air and water economizer, evaporative cooler, or ground water instead of refrigeration.
6. Use cost-effective high-efficiency compressors, fans, pumps, and motors as well as evaporative-cooled condensers in PUs. Use adjustable-frequency fan speed modulation for large centrifugal fans. Equipment should be properly sized. Over-sized equipment will not be energy efficient.
7. Use heat recovery systems and waste heat for winter heating or reheating. Use a heat-pump system whenever its  $COP_{hp}$  is greater than 1.
8. For medium- and large-size air-conditioning systems, use VAV systems instead of CV systems except for health care or applications where dilution of air contaminant is needed. Use variable flow for building-loop and distribution-loop water systems.
9. Use double- and triple-pane windows with low emissive coatings. Construct low U-value roofs and external walls.

## 9.16 Desiccant Dehumidification and Air-Conditioning

*Zalman Lavan*

### Introduction

Desiccant air-conditioning is a promising emerging technology to supplement electrically driven vapor compression systems that rely almost exclusively on R22 refrigerant that causes depletion of the ozone layer. To date, this technology has only a limited market, e.g., in supermarkets where the latent heat loads are very high, in specialized manufacturing facilities that require very dry air, and in hospitals where maximum clean air is required. However, recent emphasis on increased air change requirements (see ASHRAE standards, ANSI 62-1989), improved indoor air quality, and restriction on use of CFC refrigerants (see The Montreal Protocol Agreement, as amended in Copenhagen in 1992, United Nations Environmental Programme, 1992) may stimulate wider penetration of desiccant-based air-conditioning which can be used as stand-alone systems or in combination with conventional systems. (See [Table 9.4.1](#) for properties of some refrigerants.)

### Sorbents and Desiccants

**Sorbents** are materials which attract and hold certain vapor or liquid substances. The process is referred to **absorption** if a chemical change takes place and as **adsorption** if no chemical change occurs. **Desiccants**, in both liquid and solid forms, are a subset of sorbents that have a high affinity to water molecules. Liquid desiccants *absorb* water molecules, while solid desiccants *adsorb* water molecules and hold them on their vast surfaces (specific surface areas are typically hundreds of square meters per gram).

While desiccants can sorb water in both liquid and vapor forms, the present discussion is limited to **sorption** of water vapor from adjacent air streams. The sorption driving force for both liquid and solid desiccants is a vapor pressure gradient. Adsorption (in solid desiccants) and absorption (in liquid desiccants) occur when the water vapor partial pressure of the surrounding air is larger than that at the desiccant surface. When an air stream is brought in contact with a desiccant, water vapor from the air is attracted by the desiccant, the air is **dehumidified**, and the water content of the desiccant rises. As the water sorbed by the desiccant increases, the sorption rate decreases and finally stops when *sorption equilibrium* is reached. For dehumidification to be resumed, water must be removed from the desiccant by heating. This process is referred to as **desorption**, **reactivation**, or **regeneration**. The heat of sorption (or desorption) is generally higher than the latent heat of vaporization of water; it approaches the latter as sorption equilibrium is reached.

Some typical *liquid desiccants* are water solutions of calcium chloride (CaCl), lithium chloride (LiCl), lithium bromide (LiBr), and triethylene glycol. The equilibrium water vapor pressure at the solution surface as a function of temperature and water content is shown in [Figure 9.16.1](#) for water-lithium chloride solution. The surface vapor pressure (and dew point) increases with increasing solution temperature and decreases with increasing moisture content.

Common *solid desiccants* are silica gel, molecular sieves (zeolites), activated alumina, and activated carbon. The equilibrium sorption capacity (or moisture content) at a constant temperature, referred to as an **isotherm**, is usually presented as percent water (mass of water divided by mass of dry desiccant) vs. percent relative humidity (vapor pressure divided by saturation vapor pressure). Sorption capacity decreases with increasing temperature, but the spread of isotherms is relatively small (especially for concave down isotherms). [Figure 9.16.2](#) shows normalized loading (sorption capacity divided by sorption capacity at 100% relative humidity) vs. relative humidity for silica gel, molecular sieve, and a generic desiccant, type 1 (modified) or simply 1-M (Collier et al., 1986).

FIGURE 9.16.1 Surface vapor pressure of water-lithium chloride solutions. (Source: ASHRAE 1993, *Fundamentals Handbook*, chap. 19. With permission.)

FIGURE 9.16.2 Normalized solid desiccant isotherms.

## Dehumidification

Dehumidification by vapor compression systems is accomplished by cooling the air below the dew point and then reheating it. The performance is greatly hindered when the desired outlet dew point is below 40°F due to frost formation on the cooling coils (*ASHRAE, Systems and Equipment Handbook, 1992*).

*Desiccant dehumidification* is accomplished by direct exchange of water vapor between an air stream and a desiccant material due to water vapor pressure difference. [Figure 9.16.3](#) shows the cyclic operation of a desiccant dehumidification system.

**FIGURE 9.16.3** Cyclic dehumidification processes.

In *sorption* (1–2), dry and cold desiccant (point 1) sorbs moisture since the vapor pressure at the surface is lower than that of the air stream. During this process the moisture content (loading or uptake) increases, the surface vapor pressure increases, and the liberated heat of sorption raises the desiccant temperature. During *desorption* (2–3), the desiccant is subjected to a hot air stream, and moisture is removed and transferred to the surrounding air. The surface vapor pressure is increased and the desiccant temperature rises due to the added heat. The cycle is closed by *cooling* (3–1). The desiccant is cooled while its moisture content is constant and the surface vapor pressure is lowered. The above cycle of sorption, desorption, and cooling can be modified by combining the sorption process with cooling to approach isothermal rather than adiabatic sorption.

### Desirable Characteristics for High-Performance Liquid and Solid Desiccant Dehumidifiers

- High equilibrium moisture sorption capacity
- High heat and mass transfer rates
- Low heat input for regeneration
- Low pressure drop
- Large contact transfer surface area per unit volume
- Compatible desiccant/contact materials
- Inexpensive materials and manufacturing techniques
- Minimum deterioration and maintenance

### Additional Requirements for Liquid Desiccant Dehumidifiers

- Small liquid side resistance to moisture diffusion

Minimum crystallization

### Additional Requirements for Solid Desiccant Dehumidifiers

The desiccant should not deliquesce even at 100% relative humidity.

The airflow channels should be uniform.

The desiccant should be bonded well to the matrix.

The material should not be carcinogenic or combustible.

### Liquid Spray Tower

Figure 9.16.4 is a schematic of a liquid spray tower. A desiccant solution from the sump is continuously sprayed downward in the absorber, while air, the process stream, moves upward. The air is dehumidified and the desiccant solution absorbs moisture and is weakened. In order to maintain the desired solution concentration, a fraction of the solution from the sump is passed through the regenerator, where it is heated by the heating coil and gives up moisture to the desorbing air stream. The strong, concentrated solution is then returned to the sump. The heat liberated in the absorber during dehumidification is removed by the cooling coil to facilitate continuous absorption (see Figures 9.16.1 and 9.16.3). The process air stream exits at a relatively low temperature. If sufficiently low water temperature is available (an underground well, for example), the process stream could provide both sensible and latent cooling.

FIGURE 9.16.4 Liquid desiccant dehumidifier with heating and cooling coils.

The heating and cooling coils, shown in Figure 9.16.4, are often eliminated and the liquid solutions are passed through heating and cooling heat exchangers before entering the spray towers.

### Advantages

The system is controlled to deliver the desired level of dry air by adjusting the solution concentration.

Uniform exit process stream conditions can be maintained.

A concentrated solution can be economically stored for subsequent drying use.

The system can serve as a humidifier when required by simply weakening the solution.

When used in conjunction with conventional A/C systems, humidity control is improved and energy is conserved.

### Disadvantages

Some desiccants are corrosive.

Response time is relatively large.

Maintenance can be extensive.

Crystallization may be a problem.

## Solid Packed Tower

The dehumidification system, shown in [Figure 9.16.5](#), consists of two side-by-side cylindrical containers filled with solid desiccant and a heat exchanger acting as a desiccant cooler. The air stream to be processed is passed through dry desiccant in one of the containers, while a heated air stream is passed over the moist desiccant in the other. Adsorption (1–2) takes place in the first container, desorption (2–3) in the other container, and cooling (3–1) occurs in the desiccant cooler. The function of the two containers is periodically switched by redirecting the two air streams.

**FIGURE 9.16.5** Solid packed tower dehumidification.

### Advantages

- No corrosion or crystallization
- Low maintenance
- Very low dew point can be achieved

### Disadvantages

- The air flow velocity must be low in order to maintain uniform velocity through the containers and to avoid dusting.
- Uniform exit process stream dew point cannot be maintained due to changing moisture content in the adsorbing desiccant.

## Rotary Desiccant Dehumidifiers

A typical rotary solid desiccant dehumidifier is shown in [Figure 9.16.6](#). Unlike the intermittent operation of packed towers, rotary desiccant dehumidifiers use a wheel (or drum) that rotates continuously and delivers air at constant humidity levels.

**FIGURE 9.16.6** Rotary desiccant dehumidification wheel.

Desiccant wheels typically consist of very fine desiccant particles dispersed and impregnated with a fibrous or ceramic medium shaped like a honeycomb or fluted corrugated paper. The wheel is divided into two segments. The process stream flows through the channels in one segment, while the regenerating (or reactivating) stream flows through the other segment.

### Desiccant Material

The desired desiccant properties for optimum dehumidification performance are a suitable isotherm shape and a large moisture sorption capacity. The isotherms of silica gel are almost linear. The moisture sorption capacity is high; the desiccant is reactivated at relatively low temperatures and is suitable for moderate dehumidification. Molecular sieves have very steep isotherms at low relative humidity. The desiccant is reactivated at relatively high temperatures and is used for deep dehumidification. The isotherm of the type 1-M yields optimum dehumidification performance (Collier et al., 1986), especially when used in conjunction with high regeneration temperatures.

### The Desiccant Wheel

Some considerations for selection of desiccant wheels are:

- Appropriate desiccant materials
- Large desiccant content
- Wheel depth and flute size (for large contact surface area and low pressure drop)
- Size and cost

The actual performance depends on several additional factors that must be addressed. These include:

- Inlet process air temperature and humidity
- Desired exit process air humidity
- Inlet reactivating air temperature and humidity
- Face velocity of the two air streams
- Size of reactivation segment

It should be noted that:

Higher inlet process air humidity results in higher exit humidity and temperature (more heat of sorption is released).

Lower face velocity of the process stream results in lower exit humidity and higher temperature.

Higher regeneration temperatures result in deeper drying, hence lower exit process air humidity and higher temperature.

When lower exit air temperature is required, the exit process air should be cooled by a heat exchanger.

Final cooling of the exit process air can be achieved by partial humidification (this counteracts in part previous dehumidification).

The following is a range of typical parameters for rotary desiccant wheels:

Rotation speed: 4 to 10 rpm

Desiccant fraction: 70 to 80%

Flute size: 1 to 2 mm

Reactivation segment: 25 to 30% of wheel

Face velocity: 300 to 700 fpm

Reactivating temperature: 100 to 300°F

## Hybrid Cycles

A limited number of hybrid systems consisting of desiccant dehumidifiers and electrically driven vapor compression air-conditioners are presently in use in supermarkets. This application is uniquely suited for this purpose since the latent heat loads are high due to the large number of people and frequent traffic through doors. Also, low relative humidity air is advantageous for open-case displays.

Vapor compression systems are inefficient below a dew point of 45 to 50°F. When used in supermarkets, they require high airflow rates, the air must be reheated for comfort, and the evaporator coils must be defrosted frequently. Hybrid systems offer improved performance and lower energy cost in these cases.

Figure 9.16.7 shows a typical hybrid air-conditioning system for supermarkets. A mixture of outdoor and recirculated air is first passed through the desiccant and sensible heat exchanger wheels, where it is dehumidified and precooled. It then enters the conventional chiller before it is introduced to the interior of the supermarket. The sensible heat exchanger wheel is cooled by outdoor air and the desiccant wheel is regenerated by air heated with natural gas. Energy cost can be further reduced by preheating the reactivating air stream with waste heat rejected from the condenser of the refrigeration and/or air-conditioning systems.

The advantages of these hybrid systems are

Air-conditioning requirement is reduced by up to 20%.

The vapor compression system operates at a higher coefficient of performance (COP) since the evaporator coils are at a higher temperature.

Airflow requirements are reduced; electric fan energy is saved and duct sizes are reduced.

The refrigeration cases run more efficiently since the frequency of defrost cycles is greatly reduced.

## Solid Desiccant Air-Conditioning

Several stand-alone desiccant air-conditioning systems were suggested and extensively studied. These systems consist of a desiccant wheel, a sensible heat exchanger wheel, and evaporating pads. Sorption can be adiabatic or cooled (if cooling is combined with sorption). When room air is dehumidified and recirculated, the system is said to operate in the **recirculating** mode. When 100% outside air is used as the process stream, the system operates in the **ventilating mode**.

FIGURE 9.16.7 Hybrid air-conditioning system for supermarkets.

### Ventilation Mode

In the *adsorption path* the process air stream drawn from the outdoors is passed through the dry section of the desiccant wheel where it is dehumidified and heated by the liberated heat of sorption. It then passes through the sensible heat exchanger wheel and exits as dry but slightly warm air. The hot and dry air leaving the dehumidifier enters the heat exchanger, where it is sensibly cooled down to near room temperature. It is then passed through the evaporative cooler, where it is further cooled and slightly humidified as it enters the conditioned space.

In the *desorption path*, air is drawn from the conditioned space; it is humidified (and thus cooled) in the evaporative cooler. The air stream enters the sensible heat exchanger, where it is preheated, and it is then heated to the desired regeneration temperature by a suitable heat source (natural gas, waste heat, or solar energy), passed through the desiccant wheel (regenerating the desiccant material), and discharged out of doors.

*Performance.* In order to achieve high performance, the maximum moisture content of the desiccant should be high and the isotherm should have the optimum shape (1 M). In addition, Zheng et al. (1993) showed that the optimum performance is very sensitive to the rotational speed of the desiccant wheel. Glav (1966) introduced stage regeneration. He showed that performance is improved when the reactivation segment of the wheel is at a temperature which increases in the direction of rotation. Collier (Collier et al., 1986) showed that well-designed open-cycle desiccant cooling systems can have a thermal COP of 1.3. This, however, would require the use of high-effectiveness sensible heat exchangers, which would be large and expensive. Smaller and more affordable heat exchangers should yield system COPs in the order of unity. An extensive review of the state-of-the-art assessment of desiccant cooling is given by Pesaran et al. (1992).

### Conclusions

Desiccant-based air-conditioning offers significant advantages over conventional systems. Desiccant systems are already successfully used in some supermarkets. It is expected that these systems will gradually attain wider market penetration due to environmental requirements and potential energy savings.

The advantages of desiccant air-conditioning are summarized below:

No CFC refrigerants are used.

Indoor air quality is improved.

Large latent heat loads and dry air requirements are conveniently handled.

Individual control of temperature and humidity is possible.

The energy source may be natural gas and/or waste heat.

Less circulated air is required.

Summer electric peak is reduced.

## Defining Terms

**Absorb, absorption:** When a chemical change takes place during sorption.

**Adsorb, adsorption:** When no chemical change occurs during sorption.

**Dehumidification:** Process of removing water vapor from air.

**Desiccant:** A subset of sorbents that has a particular affinity to water.

**Desorb, desorption:** Process of removing the sorbed material from the sorbent.

**Isotherm:** Sorbed material vs. relative humidity at a constant temperature.

**Reactivation:** Process of removing the sorbed material from the sorbent.

**Recirculation:** Indoor air only is continuously processed.

**Regeneration:** Process of removing the sorbed material from the sorbent.

**Sorbent:** A material that attracts and holds other gases or liquids.

**Sorption:** Binding of one substance to another.

**Staged regeneration:** When the temperature of the regeneration segment of the desiccant wheel is not uniform.

**Ventilation mode:** 100% of outdoor air is processed.

Electronic packaging is the art and science of connecting circuitry to reliably perform some desired function in some application environment. Packaging also provides ease of handling and protection for assembly operations. This chapter defines chip, or die-level, and assembly-level packaging, with an emphasis on recent technologies. The relative advantages of each technology will be discussed in relation to performance, cost, reliability, and manufacturability. Extensive details on electronic packaging can be found in the references.<sup>1-6</sup>

### 10A.1.1 Packaging the Die

---

A semiconductor device, also known as a *die* or *chip*, is fragile and must be packaged for protection and for interfacing with the outside world. The chip package provides an electrical interconnection to the assembly, module, or display and protects the chip in the manufacturing and application environments. A number of different materials can be used in the die package, including ceramics, plastics, and metals. Single-chip, three-dimensional, and multichip module (MCM) packages are some of the packaging formats. Interconnection is the process and technique of making electrical connections between the bond pads of the chip and a leadframe, substrate, or even another chip.

#### Plastic Die Package

Plastic packages are very popular in commercial applications because of their low cost and small size compared to ceramic packages. The cost of plastic packages is typically one half to one tenth the cost of comparable ceramic or metal packages. More than 98% of all integrated circuits were packaged in plastic in 1992. In a plastic package, the chip is encapsulated by a polymer, usually referred to as the *encapsulant*. An encapsulant is generally an electrically insulating material formulation that protects an electronic device and die-leadframe assembly from the adverse effects of handling, storage, and operation.

**FIGURE 10A.1.1** Shrinking size of packaging.

Figure 10A.1.1 depicts the evolution of packaging shrinkage through the last three decades. Packaging size is being pressed by the shrinking feature size (approximately 15% per year) of CMOS integrated circuits. Package lead styles have changed dramatically from the 1970s when the dual in-line package (DIP) and pin grid array dominated the semiconductor industry. Even today, the DIP retains a sizable share of the market in which low-cost, rugged packaging meets the application need. Generally, there are at least three major lead types, with numerous variations of each: the through-hole, the surface-mount (J- or gull-lead), and the solder ball. The through-hole and leaded surface-mount packages usually have a leadframe to which the die is mounted. The plastic solder ball packages typically employ organic substrates that redistribute the die inputs-outputs (I/O) to an array or perimeter pattern of solder balls. (Substrate technologies are addressed in Section 10A.1.2.)

In the late 1980s, 1.27-mm pitch, surface-mount technology became prominent. As device complexity increased, the I/O count also increased. To keep electrical performance and package sizes reasonable, the lead pitch decreased, and fine-pitch leaded devices (lead pitch of less than or equal to 0.65 mm) were introduced.

Array packaging was first introduced in the mid-1970s with ceramic pin grid array packages. Surface-mount array packages evolved to plastic ball grid array (PBGA) and chip-scale packages (CSP). Solder

**TABLE 10A.1.1 Typical Coplanarity Requirements for SMT Components<sup>7</sup>**

<b>Component</b>	<b>Pitch (mm)</b>	<b>Coplanarity Requirement (mm)</b>
Leaded SMT	—	0.10
PBGA	1.27–1.5	0.20
	1.0	0.15
	<1.0	0.08
CBGA	—	0.15
CSP	—	0.08

From Hwang, J.S., BGA and CSP solder spheres, *Surface Mount Technology*, April, p. 18, 1999. © 1999 by IHS Publishing Group (www.smtmag.com). With permission.

spheres — usually composed of 63% tin and 37% lead, 62/36/2 (% silver), or high-temperature 10/90 — form the connection between the package and the board.

The chip-scale package is typically defined as being not more than 20% larger than the die. The CSP interposer buffers the final assembly from die-shrink redesign. The interposer can be organic substrate, tape-automated bonded (TAB), or ceramic substrate. The interposer can also act as a stress buffer between the low thermal expansion of the semiconductor die and the higher expansion of the substrate. Tessera (San Jose, CA) adds a patented elastomer between the die and the interposer to further buffer the solder balls. While the majority of CSP used today have solder-ball interconnects, there are non-solder-ball variations that meet the CSP definition, such as the small-outline, no-lead (SON) and bottom-leaded plastic packages (BLP).

The coplanarity of surface-mount parts is an important mechanical parameter in assembly. Non-planar parts can lead to poor assembly yields (voids, electrical opens) and unreliable connections (misregistration). [Table 10A.1.1](#) outlines typical coplanarity requirements.

Encapsulation techniques include molding, potting, glob-topping, and conformal coating, but the majority of encapsulated packages use the molding process. The molding compound is a proprietary multicomponent mixture of an encapsulating resin with various types of additives. The principal active and passive (inert) components in a molding compound include curing agents or hardeners, accelerators, inert fillers, coupling agents, flame retardants, stress-relief additives, coloring agents, and mold-release agents. Molding compounds have moved steadily toward all-epoxy systems.

Thermosetting encapsulation compounds are based on epoxy resins. In electrical and electronic applications, three types of epoxy resins are commonly used: the diglycidyl ethers of bisphenol A (DGEBA) or bisphenol F (DGEBF), the phenolic and cresol novolacs, and the cycloaliphatic epoxides. Novolac-based epoxies are supplied as molding bricks (preforms) that are ready for use in transfer-molding machines to produce single-in-line packages, dual-in-line packages, plastic leaded chip carriers, quad flatpacks, various types of small-outline integrated circuits (SOIC), and ball grid array packages.

Pin grid array carriers, some ball grid array packages, and carriers with metal cans frequently use multicomponent liquid epoxies or preforms. Flip chips mounted on organic substrates also use liquid epoxy underfills to protect the die surface environmentally as well as to provide stress relief to the solder balls. Polyurethanes, polyamides, and polyesters are used to encase modules and hybrids intended for use under low-temperature and high-humidity conditions. Modified polyimide encapsulants have the advantages of thermal and moisture stability, low coefficient of thermal expansion, and high material purity. Thermoplastics are rarely used because they generally require processing conditions of unacceptably high temperature and pressure, are low-purity materials, and can induce high moisture-induced stresses.

Several molding techniques ([Table 10A.1.2](#)) are available for the manufacture of plastic cases. The most widely used manufacturing process is the transfer molding process, used for molding thermosetting polymers. These polymers are plastic or fluid at low temperatures but, when heated, react irreversibly to

**TABLE 10A.1.2 Comparison of Molding Processes**

<b>Molding type</b>	<b>Advantages</b>	<b>Disadvantages</b>
Transfer molding	Multiple cavities, high yield Relative material savings Short cycle time Low tool maintenance costs	High molding pressure High viscosity Restricted to the packaging of leadframes
Injection molding	Good surface finish Good dimensional control	Poor material availability
Reaction-injection molding	Energy efficiency Low mold pressure Good wetting of chip surface Adaptability to TAB	Few resin systems available for electronic packaging Requires good mixing

form a cross-linked network no longer capable of being melted. Other processes include the injection molding process and the reaction-injection molding process.

## Hermetic (Metal and Ceramic) Packages

Hermetic packages have been used predominantly for military and government applications because of their perceived reliability advantage over plastic packages. They have also been employed in some high-power applications when heat must be dissipated from the device. Metal packages are typically used for small integrated circuits with a low lead count and in applications that require electromagnetic shielding.

Both metal and ceramic packages can be made nearly impervious to moisture when hermetically sealed. A package is classified as hermetic if it has a minimal leak rate (the rate at which gases can diffuse into or out of the package). Typical acceptable helium leak rates depend on the package size and helium pressure in the package. Some metal packages (e.g., Olin Metal quad flatpacks) are sealed using epoxies and, therefore, are not hermetic.

Several major semiconductor companies (Intel, Motorola, and AMD) have announced their exit from military markets, and the availability of these packages is shrinking dramatically. Plastic components are finding their way into many applications that had once been dominated by hermetic packages.

## Interconnection Technologies at the First Level of Packaging

The major interconnection technologies at the first level of packaging are wirebonding, flip chip, and TAB. Wirebonding, the mainstay of the microelectronics industry, still accounts for more than 98% of all semiconductor interconnections. Invented more than 30 years ago, flip chip was once available only to large, vertically integrated companies. Now, contract sources of wafer bumping are available, making flip chip one of the fastest growing interconnect methods. Tape-automated bonding (TAB) techniques are mature, although they are utilized only in limited, specialized applications because of high tooling costs. Chip stacking or three-dimensional (3-D) interconnection is typically used in systems where size, weight, and speed are critical. Comparisons of these technologies are provided in [Tables 10A.1.3](#) and [10A.1.4](#).

### Wirebond Interconnects

Wirebond interconnects are formed by metallurgically bonding a small-diameter wire from the semiconductor device to the leadframe, substrate, or other semiconductor. The wirebond forms a low-resistance path for signal propagation. Typical wire materials include aluminum, gold, and copper. Gold is usually bonded by thermo-compression, while aluminum is usually bonded ultrasonically.

Common materials for pads on bondable surfaces include aluminum, gold, silver, nickel, and copper. Aluminum and gold are the most frequently used bondpad materials. Silver has been used as a bondable plating material on leadframes and as a bondable thick-film metallization in alloy form with platinum

**TABLE 10A.1.3 Comparison of Interconnect Technologies**

<b>Attribute</b>	<b>Wirebonding</b>	<b>TAB</b>	<b>Flip TAB</b>	<b>Flip Chip</b>	<b>High-Density Interconnects</b>
Minimum (and typical) I/O pitch ( $\mu\text{m}$ )	100 (150)	50 (100)	50 (100)	125 (250)	25/1 (50/2)
Maximum I/O range	256–500	400–700	400–700	>800	>1000

Tool availability	Excellent	Fair	Fair	Fair	Fair
Technology maturity	Excellent	Good	Good	Good	Fair
Market share	98%	<2%	<1%	<1%	<1%
Cost	Low	Medium	Medium	High (potentially low)	High (potentially low)

**TABLE A10.1.4 Relative Advantages of Interconnect Technologies**

	<b>Advantages</b>	<b>Disadvantages</b>
Wirebond	Low resistance interconnects Low capital investment Mature technology Highly stable manufacturing process	Potential for cross-talk High lead inductance Use of costly, precious metal wire Low interconnect density Limited chip size
Flip chip	Self-alignment during die joining Automatic die placement and testing Low lead inductance Less need for precious metals Simultaneous bonding	Potential for solder fatigue Thermal dissipation concerns
TAB	Lightweight packaging Small size/high I/O-count Simultaneous bonding	High capital investment
HDI	Power and signal distribution High frequency performance High clock-rate performance High wiring densities High device-to-substrate area ratio	Process not fully mature High cost of deposited HDI
3-D	Increased package density Better board utilization Increased electrical performance Shorter interchip connections Lower system power	Potential for cross-talk Thermal dissipation concerns Poor yields Process not fully mature

or palladium.<sup>8</sup> Nickel has been widely used as a substitute for gold in power devices. In addition, nickel or chromium serve as barrier layers to avoid unwanted intermetallic compounds and to facilitate adhesion.

Thermocompression and thermosonic bonds are typically used to produce a ball bond on the first bond and a wedge bond on the second. Thermocompression is used on gold and in plastic packages to prevent wire sweep. Thermocompression bonds occur when two metal surfaces are brought into intimate contact through a controlled time, temperature, and pressure cycle. Typical bonding temperatures during thermocompression bonding range from 300 to 400°C. Heat is generated during the manufacturing process, either by a heated pedestal on which the assembly is placed for bonding or by a heated capillary feeding the wire. Typically, bonding time is in the neighborhood of 40 ms, which translates to a machine speed of approximately two wires per second.

Thermosonic bonding combines ultrasonic energy with the ball-bonding capillary technique of thermocompression bonding. The processes are similar, but in thermosonic bonding the capillary is not heated and substrate temperatures are maintained between 100 and 150°C. Ultrasonic bursts of energy make the bond. Typically, at the second bond, the capillary leaves a characteristic circular pattern called a *crescent bond*. The bonding time is usually about 20 ms, or a machine speed of ten wires per second, for ball bonding and three wires per second for wedge bonding.

Ultrasonic bonding is a low-temperature process in which the source of energy for the metal welding is a transducer vibrating the bonding tool parallel to the bonding pad in a frequency range from 20 to 60 kHz. Ultrasonic bonding uses aluminum wire in ceramic/metal packages. Ultrasonic processes are used for wedge-wedge bonds, for which a common centerline and careful alignment during manufacture are critical to avoid large stresses and irregular deformation. Normally, the first bond is made to the die and the second to the substrate. Referred to as *forward bonding*, this is the preferred bonding procedure because it is less susceptible to edge shorts between the die and the wire. Typical bonding time for

ultrasonic bonding is about 20 ms, which translates to a machine speed of four wires per second. A disadvantage of wedge bonding over ball bonding is the necessity of maintaining the directional first-to-second alignment by rotating and aligning the die and substrate with the direction of the wire. Rotation is difficult in large MCMs (>7 cm on the side), as most equipment was designed for much smaller integrated circuit (IC) bonding. Thus, while ultrasonic bonding has the advantage of small bond pitch, the overall speed of the process is less than that for thermosonic bonds, due to machine rotational movements.

Some quality/infant-mortality failure mechanisms associated with wirebonding include cratering of the die or chip-out due to excessive bond stress on the die. It is important to maintain adequate bonding load and temperature to allow dispersion of contaminants. Cleanliness, proper atmosphere during bonding, and surface finish are also important assembly factors. Long-term failure mechanisms include differential thermal fatigue, electrical leakage, and Kirkendall voids — voids formed by different interdiffusion rates of gold and aluminum. Purple plague is a brittle, gold-aluminum intermetallic formed at high temperatures.

### Flip Chip Bonding

Flip chip bonding is an interconnection technique in which the die is connected facedown onto the substrate. Solder bumps on area-array metallized terminals are reflowed to matching footprints of pads on a substrate. Flip chip bonding grew at a rate of about 18% compound annual growth (CAG) between 1991 and 1997. With wafer bumping services readily available, growth from now to the year 2002 is projected at nearly 50% CAG. One of the first products with extensive use of flip chip packaging was a Sony camcorder that contained sixteen flip chip die on chip-scale interposers.<sup>9</sup>

The three major steps involved in manufacturing flip chip bonds are (1) die or wafer bumping, (2) alignment of the die and substrate, and (3) assembly. Flip chip technology has several advantages over wirebonding:

- Self-alignment during die joining, which allows for automatic die placement and testing
- Low lead inductances, due to shorter interconnection lengths than wirebonding
- Reduced need for precious attach metals
- Increased productivity, due to the ability to make large numbers of bonds simultaneously

Evaporating and plating are the major methods of bump formation. Evaporated bumps (125  $\mu\text{m}$  diameter and 100  $\mu\text{m}$  high) can be smaller and more uniform than plated bumps (125–175  $\mu\text{m}$  diameter and 25–100  $\mu\text{m}$  high).

The flip chip assembly of a microelectronic component package is a composite of multiple, thin layers of metals. On the die bond pads, the pad structure is called *ball-limiting metallurgy* (BLM), *pad-limiting metallurgy* (PLM), or *under-bump metallurgy* (UBM). On the substrate bond pads, the connection structure is called *top-surface metallurgy* (TSM). [Figure 10A1.2](#) shows a typical flip chip bond structure.

The BLM structure and solder bump manufacturing, called the *bumping process*, can be implemented using a variety of methods, including metal masking, photolithography, electroplating and ultrasonic soldering, maskless bumping, and copper bumping. Critical properties of the BLM adhesive layer include good electrical contact with the metallization pad on the die, strong adhesion to the pad and to the passivation layer surrounding it, and selective etchability of the metal layer, enabling the use of photolithography techniques during fabrication. The BLM barrier layer must also have good solderability and the capability to prevent interdiffusion between the solder and the pad metallization. Finally, the BLM bonding layer must provide an inert surface during bonding and protect the barrier layer from oxidation during storage.

The barrier layer of the TSM structure is made of a metal that increases wettability and has a surface suitable for solder reflow. The bonding layer uses metals that have the ability to retain wetting properties and provide adequate shelf life prior to die attachment. The melting point is the most important material property when selecting solder materials. High-melting-point solders are selected for die-level

**FIGURE 10A.1.2** Flip chip bond structure. (From Pecht, M. et al., *Quality Conformance and Qualification of Micro-electronic Packages and Interconnects*, John Wiley & Sons, New York. With permission.)

interconnections to enable lower melting-point solders to be used for the board-level packaging. For example, 95Pb/5Sn solder (melting point around 315°C) is used with alumina ceramic substrates for die connections, while eutectic tin lead solder (melting point around 183°C) is used to attach dies to such organic substrates as Kapton film and glass/epoxy printed wiring boards.

Also important in solder selection is the cyclic strain hardening behavior of the solder, which describes the strain induced in the solder by a given stress condition. This material property strongly influences the thermal fatigue life of the solder. A slow interdiffusion rate that reduces intermetallic formation with the metal layers on the die and the substrate pads is required to enhance the thermal fatigue life of the solder. Intermetallics, though necessary to form a good bond, may reduce the thermal fatigue life if present in excessive quantities because of their brittle nature.

High corrosion resistance is required for solders used in non-hermetic packages to prevent corrosion-related failures. High oxidation resistance is also desirable, as the operational environment in non-hermetic packages accelerates solder oxidation, first on the surface and then in the bulk solder, which can eventually result in solder-die separation. High thermal conductivity is a benefit of metallic solders that allows the heat generated by the die to be dissipated to the substrate via solder bumps.

### **Tape-Automated Bonding (TAB)**

Tape-automated bonding is particularly well suited for volume applications requiring small, lightweight, and high-I/O-count electronic packages. Furthermore, with hybrids and multichip modules, TAB has been used as a means to test and package very large-scale integration dies for a variety of products. (For TAB design guidelines and comparisons with other interconnect technologies, the interested reader is referred to Reference 2.)

The TAB assembly includes bumps, interface metallurgy, leads, lead plating, adhesive, polymeric tape, and encapsulant. In one-layer tape (all metal), the tape is made of metal foil with an etched lead pattern. In multiple-layer tape, the tape assembly consists of metal foil with an etched lead pattern and polymeric tape, with or without adhesive. A TAB assembly can be mounted onto the substrate face-up (conventional), facedown (flip-TAB), or in recessed pockets. Because of the geometry configuration, flip-TAB mounting offers options for either straight or formed leads.

**TABLE 10A1.5 Dimensions of Tape-Automated Bonds<sup>11–13</sup>**

<b>Element of TAB</b>	<b>Dimensions</b>
Bump	
Square	50–120 $\mu\text{m}$ wide and 10–30 $\mu\text{m}$ high
Truncated sphere	80- to 100- $\mu\text{m}$ diameter and 25 $\mu\text{m}$ high
Interface metallurgy	
Adhesion and barrier layers	0.08–1 $\mu\text{m}$
Bonding layer	0.1–0.3 $\mu\text{m}$
Lead	
Thickness	18–70 $\mu\text{m}$
Inner lead pitch	30–100 $\mu\text{m}$
Outer lead pitch	50–635 $\mu\text{m}$
Plating thickness	0.25–2 $\mu\text{m}$
Polymeric tape	
Width	8–70 mm
Thickness	25–127 $\mu\text{m}$
Polymeric adhesive thickness	12.7–25.4 $\mu\text{m}$
Die passivation thickness	1–1.5 $\mu\text{m}$

Common TAB dimensions are summarized in [Table 10A.1.5](#). The bump configurations in TAB can be classified as bumped die, bumped leads (BTAB), transferred bumps (TTAB), or bumpless. The bumped-die approach requires bumping the die before bonding. One-layer tape typically consists of about 70- $\mu\text{m}$ -thick etched copper foil. Two-layer tape consists of a polymeric film, approximately 50  $\mu\text{m}$  thick, and a patterned metal layer of 20 to 40  $\mu\text{m}$ . Three-layer tape consists of patterned metal, usually as sheets of electro-deposited or rolled copper (typically 35  $\mu\text{m}$  thick), laminated with an adhesive to prepunched polymeric film (typically 125  $\mu\text{m}$  thick). Two-metal-layer tapes with signal and ground planes and three-metal-layer tapes that provide signal, ground, and power planes are being used in some multichip modules.<sup>10</sup>

Ultrasonic bonding is typically used to create the inner-lead bond. The outer-lead bond can be ultrasonically bonded, adhesive bonded, or soldered to the board or substrate. The BTAB approach bonds an unbumped die to bumps on the tips of the inner leads. The TTAB approach bonds an unbumped die to bumps on a separate substrate, which are transferred to the inner leads. The bumpless TAB approach bonds the TAB inner leads directly to an unbumped die.

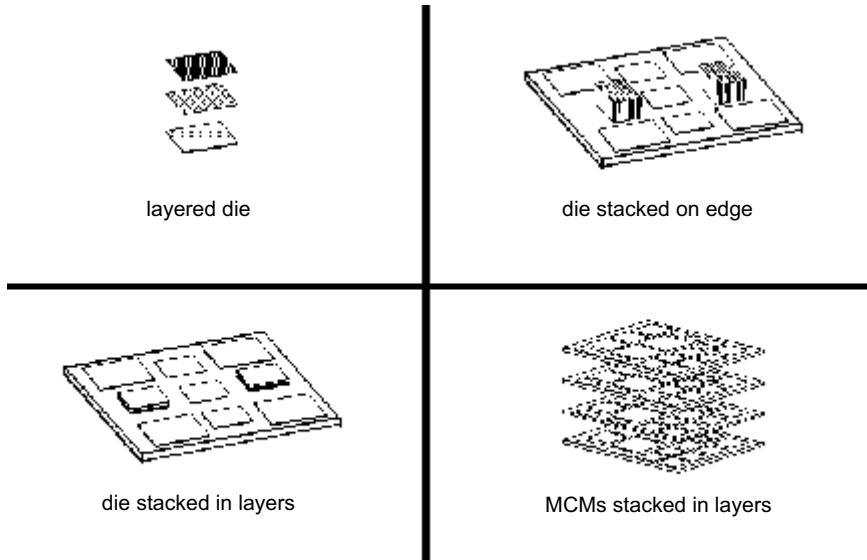

Tape-automated bonding is capable of accommodating dies with peripheral and area-array I/Os. In an area-array TAB (ATAB), a multilayer metal tape is usually used to provide interconnections between the die bumps and the substrate bonding pads. Area-array TAB increases the number of potential I/Os and improves integrated circuit design flexibility. The common inner lead pitch is 100  $\mu\text{m}$ , with 50  $\mu\text{m}$  wide lines and spacing.

The typical outer-lead pitch ranges from 200 to 625  $\mu\text{m}$ . Tape widths can range from 8 to 70 mm to accommodate various die sizes and I/O counts. Multiple-conductor (multimetal) tapes have been developed to control impedance and reduce cross-talk.<sup>10</sup> An advantage of TAB is the ability to test the components at extremely fine pitches, prior to excision of the part from the tape. This practice prevents lead damage. TAB pitches of less than 50  $\mu\text{m}$  are in production and perform electrically and thermally better than wirebonding.

Some disadvantages of TAB are tooling and nonrecurring costs. Each die design requires a new tape design. This reduces the flexibility to accommodate die shrinks.

### Three-Dimensional Die Packaging

Three-dimensional (3-D) packaging and interconnection provide increased electrical performance and packaging density compared to traditional two-dimensional (2-D) approaches. Three-dimensional

**FIGURE 10A.1.3** Types of 3-D packaging. (From Pecht, M. et al., *Quality Conformance and Qualification of Micro-electronic Packages and Interconnects*, John Wiley & Sons, New York. With permission.)

packaging and interconnection can increase density by a factor of more than 50 by stacking integrated circuits (ICs). Schematically illustrated in [Figure 10A1.3](#) are four generic types of 3-D packaging: layered dies, dies stacked on edge, dies stacked in layers, and vertically stacked multichip modules.<sup>3</sup>

Cost-effective multiple IC packages have been in high volume production for several years. A polyimide tape interposer is used to mount mirrored memory die. One example of this is a Sharp (Osaka, Japan) device that integrates a static RAM with a flash memory. The result not only enhances access time but also reduces the area to about half of the size of conventional packaging.<sup>14</sup>

Three-dimensional packaging provides increased system performance over shorter interchip connections. Also, potentially lower system power is necessary for physically smaller and fewer drivers. To reduce the package thickness and bond length, the integrated circuits are often thinned. Three-dimensional techniques incorporate many of the manufacturing processes currently used in 2-D production, adapting standard semiconductor processing equipment. Most processing is accomplished simultaneously on multiple die.

The materials used in 3-D and their critical properties are the same as those used in advanced 2-D packaging and interconnection. Common materials found in both 2-D and 3-D structures include polyimides for dielectrics, copper or aluminum for conductors, solders for bonding, and a variety of substrates using alumina, silicon, and aluminum nitride. Common properties of these materials are discussed in the literature.<sup>1,5</sup> Much of the success of 3-D packaging will depend on adhesive technology. Thermosetting adhesives used to bond the dies together in a stack, including polyimides and epoxies, are selected for strength and stability. Thermoplastic adhesives used to bond stacked substrates are selected for compliance and reworkability. In some cases, a hierarchy of adhesives, based on melting or softening temperature, is needed to allow disassembly of the structure; this is unique to 3-D technology.

The manufacturing process for 3-D microelectronic devices depends on the format chosen for the final product. The package elements of layered die include the die themselves, the dielectric between the die, and interconnects. The elements of dies stacked on edge, layered dies, and vertically stacked modules include dies, attachments between dies or modules, wires and wirebonds, and interconnects between dies or modules. The package-to-substrate interconnects are usually solder bumps or pad arrays.

[Table 10A1.6](#) compares the process attributes and interconnection techniques of some of the major 3-D package manufacturers. The manufacturing yield of 3-D packages depends on the number of directly

connected dies built into the device. For example, if the yield of a particular type of die is 90% and the completed 3-D module comprises three layers, the final yield of the module can be as low as 73%. In some format types, screening can be conducted prior to module assembly to remove defective dies from the 3-D structure or to “turn off” the defective die. In some cases, the fabrication process incorporates redundancy to minimize the number of costly screens.

In 3-D packaging, both single-level, horizontal cross-talk and cross-talk between different layers can be potential problems for very high-speed applications. Furthermore, the approach may require the use of heat spreaders when using multiple high-power devices in order to meet thermal operating specifications as well as thermal and thermomechanical stress design limits.

## 10A.1.2 Printed Wiring Board Technology

The printed wiring board is a substrate on which electronic components are mounted for electrical interconnection and mechanical support. The interconnection is provided by patterned metal tracks either on the surface or on the inner layers of the printed wiring board. Based on the raw materials used for manufacture, printed wiring boards can be either organic or ceramic boards. The most common organic board material consists of a woven glass fabric bound by a resin. Ceramic board materials typically include alumina, aluminum nitride, and beryllia. Often, in ceramic boards, materials and structures are added to create embedded capacitors and resistors, freeing precious top-layer real estate. While not widely in production, similar techniques can be used in the inner layers of organic boards.

### Conventional Printed Circuit Board Technology

Conventional printed wiring board (PWB) technology can be categorized as single layer, double layer, or multilayer. Single-layer boards have conductors etched on one side of the board, usually without hole plating. Double-layer boards have conductors on both sides of the board, but no inner layers. Multilayer organic boards typically consist of stacks of partially or fully cured fabric-reinforced epoxy sheets and copper foil conductors.

While there are many ways to fabricate a multilayer printed wiring board, a typical flow chart of the fabrication process is shown in [Figure 10A.1.4](#).<sup>1</sup> In conventional printed circuit board technology, the

**FIGURE 10A.1.4** Typical multilayer PWB fabrication process.

conductors are generally formed through both subtractive and additive processes. The partially cured laminate sheets, called *prepreg*, are cured and laminated with pressure and temperature.

The most common and least expensive resin system is FR-4 epoxy. This epoxy is a diglycidyl ether of tetrabromobisphenol A, with a glass transition temperature ranging from 135 to 180°C. Variations are

**TABLE 10A.1.7 Comparison of Common Printed Wiring Board Materials**

<b>Substrate Material</b>	<b>Glass Transition Temp. (°C)</b>	<b>Dielectric Constant @ 1 MHz</b>	<b>Dissipation Factor @ 1 MHz</b>	<b>In-Plane CTE (ppm/K)</b>	<b>Relative Cost (FR-4 = 1)</b>

Alumina	N/A	8.90	.0002–.0015	6.8	8–12

sometimes introduced in the resin to tailor desirable mechanical and electrical properties, including glass transition temperature, dielectric constant, coefficient of thermal expansion, moisture absorption, and thermal conductivity.

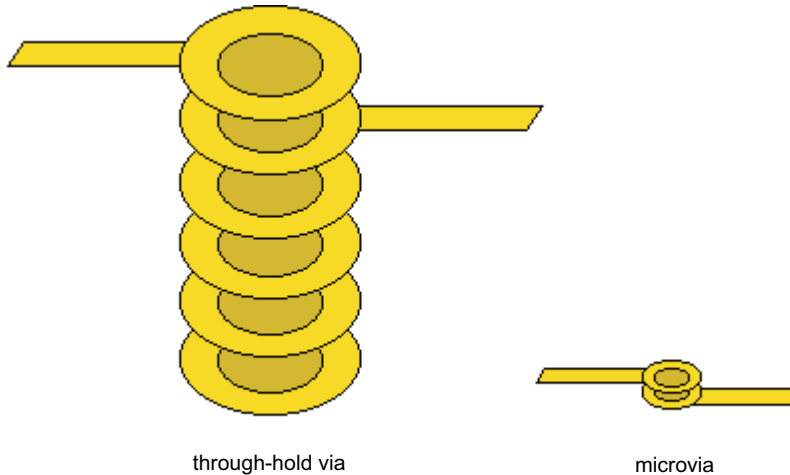

Holes in conventional PWBs are typically mechanically drilled. Those holes that allow conduction through all layers are called *plated through-holes* (PTH) for through-hole leads. For surface-mount devices, the holes are referred to as *plated through-vias* (PTV). Blind vias begin at a surface layer of the board and end at an internal layer. Buried vias are located in internal layers and do not include the external layers.

The explosion of commercial wireless (1–2 GHz) and high-performance processors (>1 GHz) is challenging the limits of FR-4. The edge rates of the signals and clock are actually more critical to application design than the clock frequency. The dissipation factor correlates with signal distortion and the dielectric constant with the signal delay. Thus, the relatively high dielectric constant of FR-4 (4.2) and high dissipation factor (0.030) make FR-4 use increasingly difficult for high-frequency (>150-MHz board frequencies) and fast-edge-rate (less than 1–2 ns) applications. While polytetrafluoroethylene (PTFE) materials have been used in military and high-end commercial applications for three decades because of their low dielectric constant of 2.4 to 2.6, these materials tend to be about 15 times costlier than FR-4. New materials such as polyphenylene oxide (PPO)/epoxy have reduced the dissipation factor significantly. Higher performance resins, such as polyfunctional FR-4 epoxy, bismaleimide triazine/epoxy (BT), cyanate esters (CE), and polyimide, are also used for a variety of special applications. Some key parameters and the relative costs of common materials are summarized in [Table 10A.1.7](#).

Printed wiring boards can also be connected by flexible dielectric materials called flex print. The rigid portion of printed wiring boards can be either organic or ceramic, while flexible circuits use thinner, flexible organic base materials, including polyester and polyimide. Flex print provides an interconnection between boards that can be electrically superior to conventional connectors.

## High-Density Interconnect Technology

Driven by increasing component I/O densities, board technology is migrating to the high-density interconnection (HDI). While there are numerous processes to form HDI layers, these can be classified into two general categories: microvia and thin-film. The microvia approach offers many advantages, including high frequency, high clock-rate performance, high wiring densities, and high ratios of active device area to substrate area. While the increased density comes at a higher cost, the per-function cost can actually be significantly lower. Thin-film HDI technology has been used in space applications and supercomputer applications.

**FIGURE 10A.1.5** Size advantage of microvia technology. (From IPC, *HDI and Microvia Technology*, Institute for Interconnecting and Packaging Electronic Circuits, Northbrook, IL, [www.ipc.org/html/hdi.htm](http://www.ipc.org/html/hdi.htm). With permission.)

### Microvia HDI

Microvia HDI is becoming increasingly important with the advent of fine pitch array packaging. The Institute for Interconnecting and Packaging Electronic Circuits (IPC) defines a microvia as a blind or buried via of less than 150  $\mu\text{m}$ , with a capture pad of less than 300  $\mu\text{m}$ . Microvias can be used with conventional boards or chip-level packaging. In conventional boards, microvia technologies can be used selectively to redistribute difficult-to-route areas and enable components on both sides of the board. Ball grid arrays (BGAs) and CSPs with pitches of less than 1 mm typically require microvia redistribution layers. Figure 10A.1.5 shows the size advantage of microvias over conventional multilayer plated through-vias. Figure 10A.1.6 is a typical microvia stack-up; note that the microvia is actually included in the component solder pad. Current volume production yields exceed 99% in Japan and Taiwan. The microvias are generally formed by three basic approaches: plasma etch, photoimaging, and laser ablation. Laser ablation is a sequential technique, while plasma etch and photoimaging form vias simultaneously. Due to the high energy and difficulty of ablating glass fiber, the materials are typically not reinforced. Mechanical drilling can also be cost effective in material from 250  $\mu\text{m}$  thick down to about 125  $\mu\text{m}$  thick.<sup>15</sup>

Because there is no glass reinforcement, the dielectric constant of FR-4 epoxy is significantly lower than its reinforced counterpart. DYCOstrate®, developed by Dyconex of Zurich, Switzerland, is widely used in East Asia. An isotropic oxygen plasma is used to form vias that range from 75 to 150  $\mu\text{m}$  in diameter. One advantage of this process is that the plasma removes all organic material, leaving the microvia clean.<sup>17</sup> The parallel processing and high yield make this process very cost effective.

A liquid- or dry-film photoimageable dielectric is generally an epoxy-acrylate material. Processing is similar to conventional soldermasking, followed by copper plating and patterning. Via diameters range from 50 to 250  $\mu\text{m}$ .

Both CO<sub>2</sub> and ultraviolet (UV) lasers can be used to ablate the dielectric; UV can also burn through the copper layers. The CO<sub>2</sub> lasers are able to produce much smaller holes (10–25  $\mu\text{m}$ ) and are faster than the UV laser (25–200  $\mu\text{m}$ ). Laser vias can be formed in a variety of ways, including a two-pass process (first through copper, followed by a dielectric at a different frequency), a combination of conventional etching through the copper and laser ablation of the dielectric, and, finally, a deposited dielectric with laser via formation followed by an additive outer copper layer.<sup>18</sup> The remaining residue at the bottom of the ablated via can be removed with potassium permanganate or plasma etching for higher aspect ratio holes.

**FIGURE 10A.1.6** Example of microvia technology. (From IPC, *HDI and Microvia Technology*, Institute for Interconnecting and Packaging Electronic Circuits, Northbrook, IL, [www.ipc.org/html/hdi.htm](http://www.ipc.org/html/hdi.htm). With permission.)

The reliability of the microvias is generally excellent, due to an aspect ratio of less than one. Other critical reliability factors are the hole diameter, plating thickness, hole cleanliness, and plating uniformity. In a sample of 15 different microvia test cases, only two test cases could not pass 2000 liquid-to-liquid thermal shock cycles ( $-55$  to  $125^{\circ}\text{C}$ ).<sup>19</sup> In another study of 18 U.S. and European fabricators, strong correlation was found between hole diameter and reliability. Holes of less than  $150\ \mu\text{m}$  were not reliable. Vias in solder pads were found to have no impact on solder-joint reliability.

### Thin-Film HDI

All thin-film HDI approaches use deposited thin-film conductors with organic or inorganic interlayer dielectrics. The materials are sputtered with processes similar to semiconductor processing. Vias provide interconnection between conductor layers. Fully assembled modules using thin-film HDI are referred to as MCM-Ds.

Thin-film HDI can be classified into four generic types: overlay HDI, reach-through via HDI, beveled die-edge HDI, and conventional, chip-last, MCM-D, thin-film conductor and deposited dielectric HDI. A chip-last approach may employ wirebonding or other interconnects for die-to-substrate connectivity.

Table 10A.1.8 illustrates some of the many manufacturers and research institutions that make various types of HDI and MCM-D substrates. Typical design considerations, such as the number of metal layers, conductor line width, line spacing, via diameter, and via pitch, are listed in Table 10A.1.8 for each manufacturer. While many layers of dielectric and metal are possible, applications are often easily routed in two signal layers and a power-and-ground layer.

### Ceramic Substrate Technology

Thick-film ceramic boards are formed by screen printing conductive, resistive, and dielectric paste onto a dielectric substrate and then firing. Typical thicknesses are in the range of  $10$  to  $60\ \mu\text{m}$ , depending on the materials. The classification “thin-film” refers to materials that are deposited in a sputtered vacuum process, similar to that used in semiconductor fabrication. Thin-film feature sizes are an order of

magnitude less than the thick-film structures. These hybrid composites can have multiple conductor layers and can include both thick- and thin-film processes.

### 10A.1.3 Printed Circuit Assembly Processes

The printed circuit assembly processes consist of placing components on the printed wiring board, soldering the components, and post-solder processing steps such as cleaning and conformal coating. Classification of soldering processes is based on the method of applying the solder and the heating processes involved. Two processes in common use are wave soldering and reflow soldering. Wave soldering is used primarily for through-hole technology, while reflow soldering is used for surface-mount assembly.

#### Through-Hole Assembly

Through-hole components can be placed manually or with automated insertion equipment. High-speed equipment can place more than a thousand devices per minute, crimp the leads on the opposite side of the board, and dress the lead to an appropriate length. In wave soldering, the board is passed over a jet of molten solder. The hydrostatic pressure of the solder from the nozzle wets the underside of the PWB and pushes the solder slightly up the plated through-hole. Subsequent capillary action, resulting from the surface tension between the solder and the walls of the plated through-hole, forces the molten solder to rise through the hole and wet the upper lands of the through-hole, securing the part in place.

Before soldering, boards must be fluxed and preheated. Fluxing consists of applying a chemical compound with activators, solvents, and detergents to the solder-joint locations to chemically clean the surfaces to be joined. Preheating reduces thermal shock to the components and the PWB, activates the flux, and evaporates any flux solvents to prevent the formation of blowholes (voids) in the solder joint.

#### SMT Assembly

The reflow soldering process consists of remelting solder previously applied to a PWB joint site (pad) in the form of a preform or paste. No solder is added during reflow. The first step in the process is to apply solder paste and any necessary adhesives to the land patterns on the printed wiring board. Adhesives are needed only if the components cannot be held in place by the tackiness of the solder paste. After

component placement, the populated PWB is transported to the preheater to evaporate solvents in the solder paste. In this stage, the temperature of the board is raised to 100 to 150°C at a rate low enough to prevent solvent boiling and the formation of solder balls; 2°C/second has been accepted as an industry norm.<sup>20</sup>

The next stage in the reflow process is slow heating, which increases the temperature to the solder melting point and activates the flux in the solder paste. The activated flux removes oxides and contaminants from the surfaces of the metals to be joined. The next stage consists of melting the solder. During the melting stage, the temperature of the solder paste is raised to just above its melting point. When the solder melts, it replaces the liquid flux formed in the previous step. The temperature is held above the melting point while the solder coats the surfaces to be joined. The temperature must be regulated to allow the melted solder particles to coalesce and form a fillet around the component lead. Excessive temperatures increase the fluidity of the solder, causing it to move away from the desired joint location, while excessively long periods at the wetting temperature may lead to intermetallic formation and embrittlement. Fillet formation is the most critical part of the reflow process. The last stage involves cooling the solder joint, either by conducting the heat through the board layers or by natural or forced convection to the ambient air.

Reflow methods differ according to the method of heat transfer to the reflow site. Conductive, convective, and radiative heat transfers are variously used for this purpose. Conductive heat-transfer methods include the soldering iron, hot-bar reflow, and conductive-belt reflow. Radiative heat-transfer methodologies include infrared, laser, and optical fiber systems. Convective heat transfer is used in vapor-phase (or condensation) reflow systems. Each method has its own merits and limitations. The most common technique for mass reflow soldering is infrared heating/convection because it allows temperature control throughout the reflow soldering cycle. However, vapor-phase soldering is still considered the best way to limit the maximum temperature reached during reflow, as the temperature in the oven never rises above the temperature of the saturated vapor.

## Connectors

Connectors can be classified based on the electronic elements being connected. Board-to-board connectors are used to connect two printed circuit boards; wire-to-board connectors are usually used to connect a source of power to a printed circuit board or to bus signals with high fidelity; and wire-to-wire connectors are generally used externally to the electronic equipment. In contemporary systems, connectors are a vital link in completing an electronic system. Connectors should be chosen carefully, taking into consideration current, voltage, impedance, EMI/EMR shielding, and allowable losses.

A connector is composed of four basic elements:<sup>21</sup> the contact interface, the contact finish, the contact spring, and the connector housing. The contact interfaces are of two kinds: separable and permanent. The separable connector allows for mating and unmating, while the permanent interface does not. The contact finish aids in establishing a contact interface and protecting the contact springs from corrosion. The contact spring is the electrically conducting element between the permanent connection to the subsystems and the separable interface that supplies the force necessary to maintain contact at the separable interface. The connector housing performs both mechanical and electrical functions by electrically insulating the individual contacts and supporting and locating them mechanically.

Board-to-board connectors are an important part of today's packaging. Commercial applications are making high-density connectors inexpensive. Mezzanine assemblies are gaining popularity, as processor modules become more complex in order to accommodate processor upgrades. One example is Intel's Pentium II® Mobile Module, which uses a 400-pin, 1.27-mm pitch connector.<sup>22</sup>

### 10A.1.4 Electronic Packaging Future

---

The future of electronic packaging promises an accelerating change. For several years now, industry roadmaps have assessed the capabilities, needs, direction, and future of electronic packaging. Hundreds

of companies, government agencies, consortia, and universities have contributed to roadmaps. There are a number of these long-range plans, including the National Electronics Manufacturing Initiative (NEMI),<sup>14</sup> the Japan Printed Circuit Association's *Report on the Technology Roadmap for Advanced System Integration and Packaging*,<sup>23</sup> and IPC's *The National Technology Roadmap for Electronic Interconnections*.<sup>24</sup> Many large companies and research universities involved in packaging, such as the University of Maryland's CALCE Electronic Products and Systems Center, also have roadmaps that complement and fill research holes.

The most recent findings are that cost is king in nearly all applications. Cost, a major driver in the advancement of technology, is also driving the trend toward electronics manufacturing service (EMS) suppliers or contract manufacturers. Cost and business pressures are fueling the 25% annual increase in EMS providers. The advantages of EMS include optimizing manufacturing cycle times, reducing working capital, and improving quality. The NEMI roadmap suggests that a downside of this EMS trend will be a slowing of research and development, as the EMS providers will push to keep the *status quo* rather than advance to less proven areas. The NEMI roadmap predicts that this will also lead to shorter product cycles and more conservative, evolutionary packaging approaches. If the new technology cannot achieve cost parity with existing technologies, then industry acceptance will be delayed. One example of this is flip chip packaging, competing with those technologies that are now widely used: CSP and BGA.<sup>25</sup>

The NEMI, IPC, and the Semiconductor Industry Association roadmaps all predict a movement from peripheral to array packaging; consequently, peripheral packages will not decrease below a 0.5-mm pitch. The growth of flip chip interconnection was seen as a growing trend in the industry by all roadmaps. The NEMI roadmap sees integral passives (resistors and capacitors) as an important part of the future in portable electronics, whereas the IPC sees the enabling technologies as immature.<sup>26</sup>

Some recent predictions from the NEMI roadmap are summarized in [Tables 10A.1.9 and 10A.1.10](#). The cost of I/O and labor to assemble packages will continue to fall dramatically. Substrate lines, spaces, and device I/O pitch will also shrink to keep pace with silicon integration. Noncontact test infrastructure

**TABLE 10A.1.9 NEMI Predictions for the Future<sup>25</sup>**

	1999	2003
IC package costs per I/O (¢)	0.7–0.9	0.4–0.6
Board assembly conversion (¢)	0.7–0.9	0.5
Substrate lines and spaces (µm)	70	35
Process test pads (mm)	0.5	Non-contact
Flip chip pad pitch (µm)	180	130

**TABLE 10A.1.10 Package Forecast by Lead Count Range**

I/O	1998	2003
4–18	28,495	38,768
20–32	16,347	20,489
36–68	8,442	18,502
72–100	2,043	5,160
104–144	1,551	3,222
148–208	922	2,378
212–304	405	1,070
308+	511	1,710
Total	58,716	91,299

From Berry, S., The future of leadcounts, *HDI*, 2(4), 14–16, 1999. With permission.

will be required to provide efficient and cost effective assurance that assemblies are functional. A shift to higher pin-count packages is also expected, as shown in Table 10A.1.10. While the current percentage of packages with a pin count greater than 304 is less than 1%, the percentage in the year 2003 will nearly double.

Electronic packaging technology will continue to enable many compact and high-speed products of the 21st century. The need for innovations in cost, yields, and productivity will certainly challenge those engineers involved in the many facets of packaging. These improvements will eventually touch and, it is hoped, enhance the quality of life of all the world's people.

## 11.1 Introduction

---

*Nam P. Suh*

Traditionally, the design field has been identified with particular end products, e.g., mechanical design, electrical design, ship design. In these fields, design work is largely based on specific techniques to foster certain product characteristics and principles. Examples include the principles of constant wall thickness, lightweight construction, and shortest load path. Also, the design field has been subdivided by an increasing reliance on specialized knowledge and the division of labor. Precision engineering and robotics are examples of subfields that are distinguished by the accuracy and reliability that the product must have. In the field of precision engineering, for instance, the dimensions of interest are nanometers, which are often encountered in the semiconductor industry. Each one of these fields also has its specific know-how and paradigms to support effective design have also sub-divided the design field.

There are three branches of design. The traditional school, which still dominates, believes that design requires experience and cannot be taught. The second group deals with optimization as a subset of design, using computer-based tools such as genetic algorithms, fuzzy logic, and the like. The third school of thought believes that there are axioms that govern good design decisions. A good designer needs to use all three methodologies.

## 11.2 Elements of the Design Process

---

*Nam P. Suh*

All design activities must do the following:

1. *Know* the “customers’ needs.”
2. *Define* the essential problems that must be solved to satisfy the needs.
3. *Conceptualize* the solution through *synthesis*, which involves the task of satisfying several different functional requirements using a set of inputs such as product design parameters within given constraints.
4. *Analyze* the proposed solution to establish its optimum conditions and parameter settings.
5. *Check* the resulting design solution to see if it meets the original customer needs.

Design proceeds from abstract and qualitative ideas to quantitative descriptions. It is an iterative process by nature: new information is generated with each step, and it is necessary to evaluate the results in terms of the preceding step. Thus, design involves a continuous interplay between *the requirements the designer wants to achieve* and *how the designer wants to achieve these requirements*.

Designers often find that a clear description of the design requirements is a difficult task. Therefore, some designers deliberately leave them implicit rather than explicit. Then they spend a great deal of time trying to improve and iterate the design, which is time consuming at best. To be efficient and generate the design that meets the perceived needs, the designer must specifically state the users’ requirements before the synthesis of solution concepts can begin.

Solution alternatives are generated after the requirements are established. Many problems in mechanical engineering can be solved by applying practical knowledge of engineering, manufacturing, and economics. Other problems require far more imaginative ideas and inventions for their solution. The word “creativity” has been used to describe the human activity that results in ingenious or unpredictable or unforeseen results (e.g., new products, processes, and systems). In this context, creative solutions are discovered or derived by inspiration and/or perspiration, without ever defining specifically what one sets out to create. This creative “spark” or “revelation” may occur, since our brain is a huge information storage and processing device that can store data and synthesize solutions through the use of associative memory, pattern recognition, digestion and recombination of diverse facts, and permutations of events. Design will always benefit when “inspiration” or “creativity,” and/or “imagination” plays a role, but this process must be augmented by amplifying human capability systematically through fundamental understanding of cognitive behavior and by the development of scientific foundations for design methods.

## 11.3 Concept of Domains

*Nam P. Suh*

Design is made up of four *domains*: the *customer domain*, the *functional domain*, the *physical domain*, and the *process domain* (see Figure 11.3.1). The domain on the left relative to the domain on the right represents “what the designer wants to achieve,” whereas the domain on the right represents the design solution, or “how the designer proposes to satisfy the problem.” Therefore, the design process can be defined as mapping from the “what” domain to the “how” domain. During product design, the mapping is from the functional domain to the physical domain. In manufacturing process design, the designer maps from the physical domain to the process domain.

**FIGURE 11.3.1** Four domains of the design world. {x} are characteristic vectors of each domain.

The customer domain is characterized by customer needs or the attributes the customer is looking for in a product, process, system, or material. In the functional domain, the designer formally specifies customer needs in terms of functional requirements (FRs). In order to satisfy these FRs, design parameters (DPs) are conceived in the physical domain. Finally, a means to produce the product specified in terms of DPs is developed in the process domain, which is characterized by process variables (PVs).

In mechanical engineering, design typically refers to product design and, often, hardware design. However, mechanical engineers also deal with other equally important designs such as software design, design of manufacturing processes and systems, and organizations. All designers go through the same thought process, although some believe that their design is unique and different from those of everyone else. In materials science, the design goal is to develop materials with certain properties (i.e., FRs). This is done through the design of microstructures (i.e., DPs) to satisfy these FRs, and through the development of material processing methods (i.e., PVs) to create the desired microstructures. To establish a business, the goals are {FRs}, and they are satisfied by structuring the organization in terms of its departments {DPs} and finding the human and financial resources {PVs} necessary to staff and operate the enterprise. Similarly, universities must define the mission of their institutions (i.e., FRs), design their organizations effectively to have an efficient educational and research enterprise (i.e., DPs), and must deal with human and financial resource issues (i.e., PVs). In the case of the U.S. government, the President of the United States must define the right set of {FRs}, design the appropriate government organization and programs {DPs}, and secure the resources necessary to get the job done {PVs}, subject to the constraints imposed by the Constitution and Congress. In all organizational designs the process domain represents the resources: human and financial.

Table 11.3 shows how seemingly different design tasks in many different fields can be described in terms of the four design domains. In the case of the product design, the customer domain consists of the customer requirements or attributes the customer is looking for in a product; the functional domain consists of functional requirements, often defined as engineering specifications and constraints; the

**TABLE 11.3 Characteristics of the Four Domains of the Design World for Various Designs: Manufacturing, Materials, Software, Organizations, and Systems**

<b>Domains Character Vectors</b>	<b>Customer Domain {CAs}</b>	<b>Functional Domain {FRs}</b>	<b>Physical Domain {DPs}</b>	<b>Process Domain {PVs}</b>
Manufacturing	Attributes which consumers desire	Functional requirements specified for the product	Physical variables which can satisfy the functional requirements	Process variables that can control design parameters (DPs)
Materials	Desired performance	Required properties	Microstructure	Processes
Software	Attributes desired in the software	Output	Input variables and algorithms	Subroutines
Organization	Customer satisfaction	Functions of the organization	Programs or offices	People and other resources that can support the programs
Systems	Attributes desired of the overall system	Functional requirements of the system	Machines or components, subcomponents	Resources (human, financial, materials, etc.)

physical domain is the domain in which the key design parameters {DPs} are chosen to satisfy the {FRs}; and the process domain specifies the manufacturing methods that can produce the {DPs}. It is indeed fortunate that all designs fit into these four domains, since in a given design task, mechanical design, software design, manufacturing issues, and organizational issues must often be considered simultaneously. Because of this logical structure of the design world, generalized design principles can be applied to all design applications, and the issues that arise in the four domains can be considered systematically and concurrently.

Customer needs are often difficult to define. Nevertheless the designer must make every effort to understand customer needs by working with customers to appreciate and establish their needs. Then these needs (or the attributes the customer is looking for in a product) must be translated into functional requirements (FRs). This must be done in a “solution neutral environment.” This means that the FRs must be defined without bias to any existing or preconceived solutions. If the FRs are defined based on an existing design, then the designer will simply be specifying the FRs of that product and creative thinking cannot be done.

To aid the process of defining FRs, QFD (quality function deployment) has been used. In QFD customer needs and the possible functional requirements are correlated and important FRs are determined. Experience plays an important role in defining FRs, since qualitative judgment is often necessary for assessing customer needs and identifying the essential problems that must be solved.

## 11.4 The Axiomatic Approach to Design

---

*Nam P. Suh*

The creative process of mapping the FRs in the functional domain to DPs in the physical domain is not unique; the solution varies with a designer's knowledge base and creative capacity. As a consequence, solution alternatives may vary in their effectiveness to meet the customer's needs. The axiomatic approach to design is based on the premise that there are generalizable principles that form the basis for distinguishing between good and bad designs.

Suh (1990) identified two design axioms by *abstracting* common elements from a body of good designs, including products, processes, and systems. The first axiom is called the *Independence Axiom*. It states that the independence of *functional requirements* (FRs) must be always maintained, where FRs are *defined as the minimum set of independent functional requirements* that characterize the design goals. The second axiom is called the *Information Axiom*, which states that among those designs that satisfy the Independence Axiom the design that has the highest probability of success is the best design. During the mapping process (for example, mapping from FRs in the functional domain to DPs in the physical domain), the designer should make correct design decisions using the Independence Axiom. When several designs that satisfy the Independence Axiom are available, the Information Axiom can be used to select the best design.

Axioms are general principles or self-evident truths that cannot be derived or proven to be true; however they can be refuted by counterexamples or exceptions. Through axioms such as Newton's laws and the laws of thermodynamics, the concepts of force, energy, and entropy have been defined. One of the main reasons for pursuing an axiomatic approach to design is the generalizability of axioms, which leads to the derivation of corollaries and theorems. These theorems and corollaries can be used as design rules that precisely prescribe the bounds of their validity because they are based on axioms. The following corollaries are presented in Suh (1990).

**Corollary 1:** (Decoupling of Coupled Designs)

Decouple or separate parts or aspects of a solution if FRs are coupled or become interdependent in the designs proposed.

**Corollary 2:** (Minimization of (FRs)

Minimize the number of FRs and constraints.

**Corollary 3:** (Integration of Physical Parts)

Integrate design features in a single physical part if FRs can be independently satisfied in the proposed solution.

**Corollary 4:** (Use of Standardization)

Use standardized or interchangeable parts if the use of these parts is consistent with FRs and constraints.

**Corollary 5:** (Use of Symmetry)

Use symmetrical shapes and/or components if they are consistent with the FRs and constraints.

**Corollary 6:** (Largest Tolerance)

Specify the largest allowable tolerance in stating FRs.

**Corollary 7:** (Uncoupled Design with Less Information)

Seek an uncoupled design that requires less information than coupled designs in satisfying a set of FRs.

The ultimate goal of axiomatic design is to establish a science base for design and improve design activities by providing the designer with a theoretical foundation based on logical and rational thought processes and tools.

## The First Axiom: The Independence Axiom

The Independence Axiom may be formally stated as:

*Axiom 1: The Independence Axiom*

Maintain the independence of the functional requirements.

As stated earlier, functional requirements, FRs, are defined as the minimum set of independent requirements that the design must satisfy. A set of functional requirements is the description of design goals. The Independence Axiom states that when there are two or more functional requirements, the design solution must be such that each of the functional requirements can be satisfied without affecting any of the other requirements. This means that the designer must choose the correct set of DPs so that functional dependence or coupling is not introduced. When there is only one FR, the Independence Axiom is always satisfied. In this case, the given design alternatives should be optimized and the second axiom, the Information Axiom, is used to select the best design.

To apply the Independence Axiom, the mapping process from the design goals to the design solutions can be expressed mathematically. The set of functional requirements that define the specific design goals constitutes a vector {FRs} in the functional domain. Similarly, the set of design parameters in the physical domain that describe the design solution also constitutes a vector {DPs}. The relationship between the two vectors can be written as

$$\{\text{FRs}\} = [A]\{\text{DPs}\} \quad (11.4.1)$$

where [A] is the design matrix that characterizes the nature of the mapping. Equation (11.4.1) may be written in terms of its elements as  $\text{FR}_i = A_{ij}\text{DP}_j$ . Equation (11.4.1) is a design equation that may be used for the design of a product or the microstructure of a material. For the design of processes, the design equation may be written as

$$\{\text{DPs}\} = [B]\{\text{PVs}\} \quad (11.4.2)$$

where [B] is the design matrix that characterizes the process design.

Designs that satisfy the Independence Axiom must have either a diagonal or triangular design matrix (see [Figure 11.4.1](#)). When the design matrix [A] is diagonal, each of the FRs can be satisfied independently by adjusting one DP. Such a design is called an *uncoupled design*. When the matrix is triangular, the independence of FRs can be guaranteed if and only if the DPs are changed in a proper sequence. Such a design is called a *decoupled* or *quasi-coupled design*. Although the design matrix is a second-order tensor (note: stress, strain, and moment of inertia are also second-order tensors), the usual coordinate transformation technique cannot be applied to Equations (11.4.1) or (11.4.2) to find the invariants such as the diagonal matrix, since [A] and [B] typically involve physical phenomena and geometric relationships that are not amenable to coordinate transformation.

In addition to the Independence Axiom, the mapping of the design goals (FRs or DPs) to design solutions (DPs or PVs, respectively) is often subject to constraints, Cs. Constraints establish the bounds on the acceptable design solutions and differ from FRs in that they do not have to be independent. Cost, for example, is often considered a constraint since it is affected by all design decisions, but the design is acceptable as long as the cost does not exceed a set limit.

### Example 1: Shaping of Hydraulic Tubes

In many applications (e.g., aircraft industry), steel tubes must be bent to complex shapes without changing the circular cross-sectional shape of the tube. To design a machine and a process that can achieve the task, the functional requirements can be formally stated as

FR1 = Bend the steel tube to prescribed curvatures.

FR2 = Maintain the circular cross section of the bent tube.

$$\begin{cases} FR_1 \\ FR_2 \\ FR_3 \end{cases} = \begin{bmatrix} X & 0 & 0 \\ 0 & X & 0 \\ 0 & 0 & X \end{bmatrix} \begin{cases} DP_1 \\ DP_2 \\ DP_3 \end{cases}$$

a) Uncoupled design

$$\begin{cases} FR1 \\ FR2 \\ FR3 \end{cases} = \begin{bmatrix} X & 0 & 0 \\ X & X & 0 \\ X & X & X \end{bmatrix} \begin{cases} DP1 \\ DP2 \\ DP3 \end{cases}$$

b) Decoupled design

$$\begin{cases} FR1 \\ FR2 \\ FR3 \end{cases} = \begin{bmatrix} X & 0 & X \\ X & X & 0 \\ X & X & X \end{bmatrix} \begin{cases} DP1 \\ DP2 \\ DP3 \end{cases}$$

c) Coupled design

**FIGURE 11.4.1** Examples of uncoupled, decoupled, and coupled designs.

One mechanical concept that can do the job is shown schematically in [Figure 11.4.2](#) for a two-dimensional bending case. It consists of a set of matching rollers with semicircular grooves on their periphery. These “bending” rollers can counterrotate at different speeds and move relative to each other to control the bending process. The centers of these two bending rollers are fixed with respect to each other, and the contact point of the bending rollers can rotate about a fixed point. A second set of “feed” rollers, which counterrotate at the same speed, feed the straight tube feedstock into the bending rollers. As the tubes are bent around the rollers, the cross-sectional shape will tend to change to a noncircular shape. The deformation of the cross section is prevented by the semicircular cam profile machined on the periphery of the bending rollers. The DPs for this design are

DP1 = Differential rotation of the bending rollers to bend the tube

DP2 = The profile of the grooves on the periphery of the bending rollers

The kinematics of the roller motion needs to be determined. To bend the tube, one of the bending rollers must rotate faster than the other. In this case, the tube will be bent around the slower roller. The forward speed of the tube is determined by the average speed of the two bending rollers. The motion of these rollers can be controlled digitally using stepping motors.

The design shown in [Figure 11.4.2](#) is an uncoupled design, since each of the proposed DPs only affects one FR. Is this the best design? The only way this question can be answered is to develop alternative designs that satisfy the FRs, constraints (Cs), and the Independence Axiom. Then the information content for each of the proposed designs must be computed so as to use the Information Axiom to select the best among the proposed designs.

## Decomposition, Zigzagging, and Hierarchy

In the preceding example the design was completed when the two FRs in the functional domain were mapped to two DPs in the physical domain. However, in many designs both the FRs and DPs must be decomposed into hierarchies because the high level conceptual design ideas need further design details before they can be implemented. To create the hierarchies for the FRs and DPs, the designer must return to the functional domain from the physical domain. As shown in [Figure 11.4.3](#), the design process requires the designer to alternate or zigzag between the functional domain and the physical domain.

FIGURE 11.4.2 Concept for tube bending.

FIGURE 11.4.3 Hierarchical decomposition of FRs and DPs and zigzag mapping.

In many organizations, functional requirements or design specifications are decomposed without zigzagging by remaining only in the functional domain. This means that the designers are not working in a *solution-neutral environment*; they are specifying the requirements for an existing design. For example, assume that the design objective is to develop a vehicle that goes forward, stops, and turns. This vehicle has to satisfy these three FRs. These FRs cannot be decomposed until they are mapped to a set of DPs in the physical domain. This high-level mapping is often referred to as the *conceptual phase* of design. If, for instance, an electric motor is adopted as a means to move forward, then the FR “go forward” would be further decomposed in terms of this physical concept, and the evolving functional hierarchy will be different from that associated with the decision to use gas turbines. Therefore, to define the FRs in a solution-neutral environment, the designer needs to “zig” to the physical domain, and after proper DPs are chosen, the designer must then “zag” to the functional domain for further decomposition.

This process of mapping and zigzagging must continue until the design is completed, resulting in the creation of hierarachical trees for both FRs and DPs. This will be illustrated in the following example.

**Example 2: Refrigerator Design**

Historically, humankind has had the need to preserve food. Now consumers want an electrical appliance that can preserve food for an extended time. The typical solution is to freeze food for long-term preservation or to keep some food at a cold temperature without freezing for short-term preservation. These needs can be formally stated in terms of two functional requirements:

- FR1 = Freeze food for long-term preservation.
- FR2 = Maintain food at cold temperature for short-term preservation.

To satisfy these two FRs, a refrigerator with two compartments is designed. The two DPs for this refrigerator may be stated as

- DP1 = Freezer section
- DP2 = Chiller (i.e., refrigerator) section

To satisfy FR1 and FR2, the freezer section should only affect the food to be frozen and the chiller (i.e., refrigerator) section should only affect the food to be chilled without freezing. In this case, the design matrix will be diagonal. However, the conventional freezer/refrigerator design uses one compressor and one fan which turns on when the freezer section temperature is higher than the set temperature, and the chiller section is cooled by controlling the opening of the vent (see Figure 11.4.4). Therefore, the temperature in the chiller section cannot be controlled independently from that of the freezer section.

Dependent Control  
 Fan -----> Freezing Room  
 Fan + Damper -----> Refrigerating Room  
 Thermo Sensor in F-Room Only  
 The Damper produces large pressure loss

a

**FIGURE 11.4.4** Conventional refrigerator/freezer cooling system.

Having chosen DP1, FR1 can now be decomposed as

FR11 = Control temperature of the freezer section in the range of  $-18^{\circ}\text{C}$ .

FR12 = Maintain the uniform temperature throughout the freezer section at the preset temperature.

FR13 = Control humidity to relative humidity of 50%.

FR2 may be decomposed in the context of DP2 as

FR21 = Control the temperature of the chilled section in the range of 2 to  $3^{\circ}\text{C}$ .

FR22 = Maintain a uniform temperature throughout the chilled section at a preset temperature to within  $1^{\circ}\text{C}$ .

To satisfy the second level FRs, i.e., FR11, FR12, FR21, etc., the designer has to conceive a design and identify the DPs for this level of decomposition. Just as FR1 and FR2 were independent from each other through the choice of proper DP1 and DP2, the FRs at this second level must also be independent from one another.

Suppose that the requirements of the freezer section will be satisfied by pumping chilled air into the freezer section, circulating the chilled air uniformly throughout the freezer section, and monitoring the returning air for temperature and moisture in such a way that the temperature is controlled independently from the moisture content of the air. Then the second level DPs may be chosen as

DP11 = Turn the compressor on or off when the air temperature is higher or lower than the set temperature, respectively.

DP12 = Blow the air into the freezer section and circulate it uniformly throughout the freezer section at all times.

DP13 = Condense the moisture in the returned air when its dew point is exceeded.

The design equation is written as

$$\begin{array}{l} |\text{FR12}| \quad |x \ 0 \ 0| \quad |\text{DP12}| \\ |\text{FR11}| = |x \ x \ 0| \quad |\text{DP11}| \\ |\text{FR13}| \quad |x \ 0 \ x| \quad |\text{DP13}| \end{array} \quad (11.4.3)$$

Equation (11.4.3) indicates that the design is a decoupled design.

The chilled section, where the food has to be kept in the range of 2 to  $3^{\circ}\text{C}$ , can now be designed. Here, again, a compressor may be used to control the air temperature within a preset range, and chilled air may be circulated to maintain a uniform temperature throughout the chilled section. This solution would result in a decoupled design as well. One of the design questions to be answered here is whether one compressor and one fan can be used to satisfy both {FR11, FR12, FR13} and {FR21, FR22}. Such a solution would minimize the information content without compromising functional independence (see Corollary 3). Most commercial refrigerators use only one compressor and one fan to achieve these goals (see [Figure 11.4.4](#)); however, many of these are coupled designs.

One can propose various specific design alternatives and evaluate the options in terms of the Independence Axiom. If a design allows the satisfaction of these FRs independently, then the design is acceptable for the set of specified FRs. If a solution that satisfies the Independence Axiom cannot be devised, then the designer must compromise the FRs by either eliminating some of the FRs or increasing the tolerance for temperature control, moisture control, etc.

One company has improved the preservation of food in their chilled section by providing one additional fan so as to be able to control the temperature of the chilled section more effectively (see [Figure 11.4.5](#)). This can be done since the evaporator was sufficiently cold to cool the air being pumped into the chiller section, even during periods when the compressor was not running. To maintain a uniform temperature distribution, extra vents were provided to insure good circulation of air. In this design, DP21 refers to

TWO COOLING FAN TYPE

Independent Control

F-Fan -----> Freezing Room  
 R-Fan -----> Refrigerating Room

Thermo Sensor in F-Room and R-Room

No Damper is Required

a

b

FIGURE 11.4.5 New refrigerator/freezer cooling system.

the fan for the chiller section, and DP22 represents the vents. The design matrix for the {FR21, FR22}–{DP21, DP22} relationship is diagonal as shown in the design equation:

$$\begin{bmatrix} \text{FR21} \\ \text{FR22} \end{bmatrix} = \begin{bmatrix} X & 0 \\ 0 & X \end{bmatrix} \begin{bmatrix} \text{DP21} \\ \text{DP22} \end{bmatrix} \tag{11.4.4}$$

The company has compared the performance of the uncoupled design with that of competing coupled designs. For instance, the new design provides much more uniform temperature in the chiller section (Figure 11.4.6a) and much less temporal fluctuation than the existing coupled designs (Figure 11.4.6b). They also found that the uncoupled design saves electricity because air can be defrosted due to the air flow into the chiller section when the compressor is not operating. They also found that this new design enables the use of a quick refrigeration mode in the chilled section by turning on the fan of the chiller section as soon as food is put into the chiller section. To cool 100 g of water from 25 to 10°C it took only 37 vs. 58 min in a conventional refrigerator (Figure 11.4.7).

According to Corollary 3 (Integration of Physical Parts), the innovative idea of using two fans and uniformly positioned ducts may or may not be the best solution if the FRs can be satisfied independently using only one fan. If there is an alternative design that can satisfy the Independence Axiom, the Information Axiom and the detailed calculation of the information content must be used to determine the better of the two designs. As discussed in “The Second Axiom: The Information Axiom” (below), the best design is the one that has the minimum information content since it has the highest probability of success.

In the preceding example, the design matrices were formulated in terms of Xs and Os to model the nature of the relationship between each FR and each DP. In some cases, this simple, conceptual notation is sufficient to complete and implement the design. However, in many cases further steps should be taken to optimize the design. This means that the FR-DP relationships must be modeled more precisely after the conceptual design is represented in terms of Xs and Os.

## Concurrent Design and Manufacturing Considerations

The previous section, Decomposition, Zigzagging, and Hierarchy, demonstrates use of the Independence Axiom during mapping from the physical domain to the process domain, i.e., product design. In order to implement the chosen DPs, the designer has to map from the physical domain to the process domain (i.e., process design) by choosing the process variables, PVs. This process design mapping must also satisfy the Independence Axiom, although sometimes the solution may simply involve the use of existing processes. When existing processes must be used to minimize capital investment in new equipment, the corresponding PVs must also be used to complete the mapping from the physical domain to the process domain. Therefore, the PVs act as constraints in choosing DPs. Since early design decisions may determine 70 to 80% of manufacturing productivity in many enterprises, the product design and process design (or selection) should be performed at the same time in order to develop designs that can be manufactured without incurring cost overruns and schedule slippage. This is sometimes called *concurrent design*.

## The Second Axiom: The Information Axiom

When there is only one FR, the Independence Axiom is always satisfied, and the only task left is to optimize the given design. Various optimization techniques have been advanced to deal with optimization problems involving one objective function. However, when there are two or more FRs, some of these optimization techniques do not work. In these cases, we must first develop a design that is either uncoupled or decoupled. If the design is uncoupled, it can be seen that each FR can be satisfied and the optimum points can be found. If the design is decoupled, the optimization technique must follow a set sequence.

For a given set of FRs, it is most likely that every designer will come up with different designs, all of which are acceptable in terms of the Independence Axiom. However, one of these designs is likely to be the superior alternative. The Information Axiom provides a quantitative means for establishing the merits of a given design, and this value is used to select the best solution. Specifically, the Information Axiom may be stated as

a

■ +2°C fixed temperature refrigeration  
(No variation of temperature)

DIVISION	SURROUND MULTI AIR FLOW		CONVENTIONAL MULTI AIR FLOW	
	FR-820NT	A COMPANY	B COMPANY	
TEMPERATURE VARIATION DEGREE	0.6°C	15°C	19°C	

b

FIGURE 11.4.6 Comparison of temperature control.

FIGURE 11.4.7 Quick refrigeration performance.

*Axiom 2: The Information Axiom*  
 Minimize the information content.

Information is defined in terms of the information content **I** that is related, in its simplest form, to the probability of satisfying a given set of FRs. If the probability of success is *p*, the information content **I** associated with the probability is defined as

$$I = -\log_2 p \tag{11.4.5}$$

Equation (11.4.5) defines information content in the units of binary digits or bits. In the general case of an uncoupled design with *n* FRs, **I** may be expressed as

$$I = -\sum_{i=1}^n \log_2 p_i = \sum_{i=1}^n I_i \tag{11.4.6}$$

where *p<sub>i</sub>* is the probability of DP<sub>*i*</sub> satisfying FR<sub>*i*</sub>. Since there are *n* FRs, the total information content is the sum of all the individual measures. When all probabilities *p<sub>i</sub>* are equal to one, the information content is zero. Conversely, the information content is infinite when one or more probabilities are equal to zero.

A design is called *complex* when its probability of success is low. The quantitative measure for complexity is the information content: complex systems require more information to make the system function (see Equation 11.4.5). Thus, a large system that is comprised of many subsystems and components is not necessarily complex. Even a small system can be complex if its probability of success is low.

**Example 3: Cutting a Rod to a Length**

Suppose we need to cut rod A to the length 1 +/- 0.000001 m and rod B to the length 1 +/- 0.1 m. Which task is more complicated?

The answer depends on the cutting equipment available for the job! However, most engineers with some practical experience would say that the one that has to be cut within 1 μm would be more difficult, because the probability of success associated with the smaller tolerance is lower than that associated

with the larger tolerance. Therefore, the job with the lower probability of success is more *complex* than the one with higher probability. The Information Axiom links the notion of complexity with the specified tolerances for the FRs: the tighter the tolerance, the more difficult it may be to choose a design solution or a system that can satisfy the FRs.

In practice, the probability of success is a function of the intersection of the tolerances defined by the designer to satisfy the FRs and the ability of the chosen system to produce the part within the specified tolerances. This value can be computed by specifying the *design range* (*dr*) for an FR and by determining the *system range* (*sr*) that the proposed design can provide to satisfy the FR. Figure 11.4.8 illustrates these two ranges graphically. The vertical axis (the ordinate) is for the probability density function and the horizontal axis (the abscissa) is for either FR or DP, depending on the mapping domains involved. When the mapping is between the functional and the physical domains (as in product design), the abscissa is for FR, whereas for mapping between the physical and the process domains (e.g., process design), the abscissa is for DP.

**FIGURE 11.4.8** Design range, system range, and common range in a plot of the probability density function (pdf) of a functional requirement.

In Figure 11.4.8 the system range is plotted as a probability density function vs. the specified FR. The intersection of the design range and the system range is called the *common range* (*cr*), and this is the only region where the design requirements are satisfied. Consequently, the area under the common range divided by the area under the system range is equal to the design’s probability of success. Then the information content may be expressed as

$$I = \log_2(A_{sr}/A_{cr}) \tag{11.4.7}$$

where  $A_{sr}$  denotes the area under the system range and  $A_{cr}$  is the area within the common range. Furthermore, since  $A_{sr} = 1.0$  and there are  $n$  FRs to satisfy in most cases, the information content may be expressed as

$$I = - \sum_{i=1}^n \log_2(1/A_{cr})_i \tag{11.4.8}$$

## 11.5 Algorithmic Approaches to Design

---

*Leonard D. Albano*

In addition to the axiomatic approach to design (see Section 11.4), there are many methods that are based on an algorithmic approach to design. In algorithmic design, the design process is identified or prescribed so that it leads the designer to a solution that satisfies the design goals. Algorithmic methods can be divided into several categories: pattern recognition, associative memory, analogy, experientially based prescription, extrapolation, interpolation, selection based on probability, etc. This section briefly discusses three common algorithmic methods for design: systematic design, the Taguchi method, and design for assembly (DFA).

### Systematic Design

Systematic design methods prescribe how design should be done and provide standardized solutions for fulfilling certain functional requirements. Examples of systematic design methods include Pahl and Beitz (1988), Hubka and Eder (1988), and the German Standards Institute (VDI). This section describes the approach advanced by Pahl and Beitz.

The method of Pahl and Beitz (1988) divides the design process into a number of steps and prescribes methods for dealing with each step. Design starts with an appreciation of customers needs, which are then clarified in terms of an overall function. By definition, the overall function of an engineering system is to convert matter (e.g., energy, materials, signals). Energy, for example, can be converted from chemical energy to mechanical and thermal energy; materials can be shaped, finished, and coated to provide particular geometries and surface finishes; and signal conversion is often used to control the conversion of energy and materials. The overall function is an abstract formulation of customers needs and is defined in terms of inputs and outputs to a system.

Next, the overall function is decomposed into a hierarchy of generic subfunctions (i.e., energy, material, and signal conversions) that the product must perform in order to meet the overall function. The combination of subfunctions is termed a *function structure*. Use of the function structure facilitates the design task by breaking down the overall, complex function into smaller problems that can be divided among a number of experts. Construction of the function structure starts with the logical analysis of the functions that must appear in the solution if the overall function is to be satisfied. For example, a device for producing small, thermoplastic parts should include the following subfunctions: feed plastic pellets, melt plastic pellets, shape molten plastic into desired part geometry, cool part, dispense part, and control material flow. This function structure may be expanded during later steps of the design process as the designer gains additional insight.

Once a simple function structure is established, the designer searches for suitable solution principles to satisfy each of the subfunctions. Solution principles consist of some underlying physical principle or principles to effect the required conversion and some geometric form. Shear and torsion, for example, are physical principles for transferring mechanical energy, and the screw drive is a geometric form that embodies these effects. Published design catalogs, such as the VDI guidelines (VDI), provide a data base of standardized solution principles which facilitates the solution process. A design concept is obtained by integrating the solution principles for each subfunction.

The quality of the proposed design concept increases with the number of solution principles that are considered for each subfunction. Therefore, multiple solution principles should be identified for each subfunction, and these solution principles can be combined in various permutations to produce a rich solution field. Formulating the required subfunctions and the proposed principles in matrices provides a convenient scheme for organizing the results (see Figure 11.5.1). Each row of the matrix refers to a subfunction and the columns of the matrix contain combinations of solution principles.

The reduction of the solution field to a few promising proposals for further development involves a number of ad hoc strategies. One strategy relies on the experience of the designer to identify those

Sub-functions		Solution Concepts					
		1	2	...	j	...	m
1	$F_1$	$S_{11}$	$S_{12}$		$S_{1j}$		$S_{1m}$
2	$F_2$	$S_{21}$	$S_{22}$		$S_{2j}$		$S_{2m}$
:	:	:	:		:		:
i	$F_i$	$S_{i1}$	$S_{i2}$		$S_{ij}$		$S_{im}$
:	:	:	:		:		:
n	$F_n$	$S_{n1}$	$S_{n2}$		$S_{nj}$		$S_{nm}$

**FIGURE 11.5.1** Matrix approach for developing solution concepts based on mapping different principles  $S_{xy}$  to each subfunction  $F_x$ .

combinations of solution principles that are not compatible with customers needs or with one another. A second strategy is to use value analysis to evaluate and compare the solution variants generated by the matrix combination. The general procedure for value analysis involves identifying evaluation criteria and assigning relative weights to each criterion. Each solution variant is then assigned a value by combining its weighted value for each criterion. The solution variants are then compared on the basis of their total weighted value, and the best solution is selected.

The selected solution concept is then developed in terms of its layout and detail specifications. Much of the design development relies on design rules and knowledge readily available in handbooks and design guidelines. In addition to the development of production drawings and specifications, detail design often involves optimization of the solution principles and their geometric forms. The reader is referred to Pahl and Beitz (1988) for additional information.

### The Taguchi Method

The Taguchi method (1987, 1993) provides a mathematical basis for analyzing product robustness and is intended as a guide for improving design quality. According to Taguchi, higher quality products satisfy customers needs with less variation and are manufactured at lower cost. This definition of quality is based on a cost model that emphasizes the costs associated with product variability. Costs due to variation include those incurred during manufacturing (such as the cost of materials, machine adjustments, and scraps) and those assumed by the customer (e.g., the cost to repair and/or replace the deficient product). The significance of the Taguchi cost model is the fact that it forces the designer to focus on *offline quality control* as a means to improve product quality.

Offline quality control (QC) is a strategy for reducing variability and improving quality during product design and process planning. It is an attempt to take advantage of the fact that most of the cost is committed during the early stages of product development, while only a very small percentage of the cost is actually expended. In contrast, the concept of *online quality control* has been used historically to advance quality products during manufacturing operations. However, during this stage of the product life cycle, much of the cost has been expended and committed. Statistical process control is an example of online quality control.

The practice of offline QC divides the design process into three stages: system design, parameter design, and tolerance design. System design refers to the conceptual phase of design when customers needs are formulated into a design problem and solutions are generated and evaluated. Once a solution is established and defined in terms of its characteristic attributes or parameters, parameter design is used to establish appropriate parameter settings so as to reduce the design's sensitivity to uncontrollable sources of variation. Taguchi refers to these conditions as *noise factors*. Environmental factors (e.g., people and ambient temperature) and time-dependent phenomena (such as tool wear and material

shrinkage) are examples of noise factors. As a last step, tolerance design is used to enhance or fine-tune the quality improvements realized during parameter design. However, tolerance design often involves a trade-off between the improved quality and the increased production costs incurred by tightening tolerances.

Parameter and tolerance design rely on experimental and mathematical techniques to determine the best design, subject to various noise factors. Various strategies may be used to conduct the experiments. Consider a system that involves five design parameters and three levels of settings — high, medium, and low — for each parameter. The simplest strategy is to investigate all possible combinations of parameters and level settings, which would require  $3^5 = 243$  sets of experiments. Instead, orthogonal arrays are an efficient and economical alternative to complete enumeration.

Figure 11.5.2 shows a portion of the L18 orthogonal array that enables a reduction in the work scope from 243 to 18 sets of experiments. The column headings A, B, C, D, and E correspond to each of the five design parameters or controllable factors, and the column entries refer to the three level settings 1, 2, and 3. Each row of the array defines an experiment as a unique combination of parameter settings. Any two columns have nine combinations of level settings — (1,1), (1,2), (1,3), (2,1), (2,2), (2,3), (3,1), (3,2), and (3,3) — and each combination appears with the same frequency. This balance is indicative of the array's orthogonality in a statistical sense because the influence of each control factor can be evaluated independently. The basic array can be extended to include the influence of noise factors and their level settings.

Experiment	Parameter Level Setting				
	A	B	C	D	E
1	1	1	1	1	1
2	2	2	2	2	2
3	3	3	3	3	3
4	1	1	2	2	3
5	2	2	3	3	1
6	3	3	1	1	2
7	1	2	1	3	2
8	2	3	2	1	3
9	3	1	3	2	1
10	1	3	3	2	2
11	2	1	1	3	3
12	3	2	2	1	1
13	1	2	3	1	3
14	2	3	1	2	1
15	3	1	2	3	2
16	1	3	2	3	1
17	2	1	3	1	2
18	3	2	1	2	3

**FIGURE 11.5.2** Portion of L18 orthogonal array to investigate all combinations of five parameters with three level settings.

Analysis of variation techniques provide a mathematical basis for organizing and interpreting the experimental results. For each performance requirement, signal-to-noise (S/N) ratio is used to express how sensitive each design parameter is to uncontrollable noise (which is indicative of *design robustness*). A robust design has a high S/N ratio and performs well despite the influence of noise. Many equations are available for calculating S/N ratios, and the selection of the appropriate equation is a function of the type of cause–effect relationship under study. Examples include *higher-is-better*, *lower-is-better*, and *nominal-is-best*. The reader is referred to Taguchi (1987, 1993) for further information.

## Design for Assembly

Design for assembly (DFA) supports the analysis and design of products for ease of assembly. Based on a collection of empirical time-study data, if–then rules, and design checklists, DFA methods and tools help the designer to focus on the relationship between the geometric features of a design and its

components and the effort and resources necessary to assemble these components into the desired product. Philips International, Hitachi, Xerox, Ford, and General Electric have been industry leaders in the adoption and dissemination of DFA. In this section the most widely known method, advanced by Boothroyd and Dewhurst (1985), is considered. The method gives the total assembly time and design efficiency, and these measures are then used to guide redesign.

The method of Boothroyd and Dewhurst (1985) starts with the description of a product's assembly sequence in terms of components, component features, and the basic assembly tasks of handling and insertion (which includes fastening). For each component involved in the assembly sequence, a catalog of generic part features is used to classify the component with respect to its difficulty for handling and insertion. These classifications are then used to determine the time required for each assembly task, and the task times are added to give the total operation time for the component. Therefore, the total assembly time (TM) for the design is the sum of the operation times for each component.

Design efficiency is the ratio of an estimated, ideal assembly time to TM. The ideal assembly time is based on a theoretical minimum number of parts (NM). The estimation of NM relies on a checklist for identifying redundant components or components that may be combined to reduce parts count. For manual assembly, the ideal assembly time is specified as 3 sec per part, and design efficiency EM is given by the equation

$$EM = 3 \times NM / TM \quad (11.5.1)$$

The resulting values for assembly time and design efficiency provide the designer with a basis for redesign. Suggested strategies for redesign include reduction in parts count, use of symmetry to facilitate handling, and use of alternative fastening mechanisms to facilitate insertion (e.g., snap-fit elements are faster to insert than parts requiring screw tightening). The reader is referred to Boothroyd and Dewhurst (1985) for further information.

## 11.6 Strategies for Product Design

---

*Michael Pecht*

### Requirements

The design team must have a clear appreciation of user requirements and constraints before a design can begin. Requirements are established within the context of product effectiveness attributes and include limits on parameters such as speed, miles per gallon, computations per second, and accuracy, as well as constraints on size, weight, reliability, and cost. Often, contractual requirements and company policy can dictate a product type, such as the use of an in-house technology or product, or the exclusion of a technology or product.

Requirements must be addressed holistically in the design of a product and must not be limited to those that affect the product's immediate performance. For example, the supportability of the product is a critical product requirement for many products in terms of the ease of maintenance and accessibility to the products, spares, support equipment, the time and required personnel to repair the product, and the ease of discovering or detecting where a problem occurs. A poor definition of requirements could lead to a design where, for example, the air conditioning compressor has to be removed to replace a spark plug, or where special tools are required to replace the oil in a car. Note also that the design team should be aware of the impact of administrative policies on the reliability of products as reflected in the product's scenario for use. For example, outdated standards can contribute to failures that are not the result of either faulty design or human error.

### The Life Cycle Usage Environment

The life cycle usage environment or scenario for use of a product goes hand-in-hand with the product requirements. The life cycle usage information describes the storage, handling, and operating stress profiles and thus contains the necessary "load" input information for effective assessment and development of design guidelines, screens, and tests. The stress profile of a product is based on the application profile and the internal stress conditions of the product. Because the performance of a product over time is often highly dependent on the magnitude of the stress cycle, the rate of change of the stress, and even the time and spatial variation of stress, the interaction between the application profile and internal conditions must be specified. Specific information about the product environment includes absolute temperature, temperature ranges, temperature cycles, temperature gradients, vibrational loads and transfer functions, chemically aggressive or inert environments, and electromagnetic conditions. The life cycle usage environment can be divided into three parts: the application and life profile conditions, the external conditions in which the product must be stored, handled, and operated, and the internal product-generated stress conditions.

The application and life profile conditions include the application length, the number of applications in the expected life of the product, the product life expectancy, the product utilization or nonutilization (storage, testing, transportation) profile, the deployment operations, and the maintenance concept or plan. This information is used to group usage platforms (i.e., whether the product will be installed in a car, boat, satellite, underground), develop duty cycles (i.e., on-off cycles, storage cycles, transportation cycles, modes of operation, and repair cycles), determine design criteria, develop screens and test guidelines, and develop support requirements to sustain attainment of reliability and maintainability objectives. The external operational conditions include the anticipated environment(s) and the associated stresses that the product will be required to survive. The stresses include temperature, vibrations, shock loads, humidity or moisture, chemical contamination, sand, dust and mold, electromagnetic disturbances, radiation, etc.

The internal operational conditions are associated with product-generated stresses, such as power consumption and dissipation, internal radiation, and release or outgassing of potential contaminants. If

the product is connected to other products or subsystems in a system, stresses associated with the interfaces (i.e., external power consumption, voltage transients, electronic noise, or dissipation) must also be included.

## **Characterization of Materials, Products, and the Manufacturing Processes**

Design is intrinsically linked to the materials, products, interfaces, and manufacturing processes used to establish and maintain functional and structural integrity. It is unrealistic and potentially dangerous to assume defect-free and perfect-tolerance materials, products, and structures. Materials often have naturally occurring defects and manufacturing processes can induce additional defects to the materials, products, and structures. The design team must also recognize that the production lots or vendor sources for products that comprise the design are subject to change. Even greater variability in products characteristics is likely to occur during the fielded life of a product as compared to its design or production life cycle phases.

Design decisions involve the selection of products, materials, and controllable process techniques, using tooling and processes appropriate to the scheduled production quantity. Often, the goal is to maximize product and configuration standardization; increase package modularity for ease in fabrication, assembly, and modifications; increase flexibility of design adaptation to alternate uses; and utilize alternate fabrication processes.

## **Design Guidelines and Techniques**

Generally, new products replace existing products. The replaced product can be used for comparisons (i.e., a baseline comparison product). Lessons learned from the baseline product can be used to establish new product parameters, to identify areas of focus in the new product design, and to avoid the mistakes of the past.

Once the products, materials, processes, and stress conditions have been characterized, design begins. In using design guidelines, there may not be a unique path to follow. Multiple branches may exist depending upon the input design constraints. The design team should explore enough of the branches to gain confidence that the final design is the best for the prescribed input information. The design team should also use guidelines for the complete design and not those limited to specific aspects of an existing design. This statement does not imply that guidelines cannot be used to address only a specific aspect of an existing design, but the design team may have to trace through the implications that a given guideline suggests.

Design guidelines that are based on physics of failure models can also be used to develop tests, screens, and derating factors. Tests can be designed from the physics of failure models to measure specific quantities and to detect the presence of unexpected flaws, manufacturing, or maintenance problems. Screens can be designed to precipitate failures in the weak population while not cutting into the design life of the normal population. Derating or safety factors can be determined to lower the stresses for the dominant failure mechanisms.

## **Preferred Products**

In many cases, a product or a structure much like the required one has already been designed and tested. This is called a “preferred product or structure” in the sense that variabilities in manufacturing, assembly, and field operation that can cause problems have been identified and corrected. Many design teams maintain a list of preferred products and structures with acceptable performance, cost, availability, and reliability.

## **Redundancy**

Redundancy permits a product to operate even though certain components and interconnections have failed. Redundant configurations can be classified as either active or standby. Elements in active redundancy operate simultaneously in performing the same function. Elements in standby redundancy are

designed so that an inactive one will be switched into service when an active element fails. The reliability of the associated function is increased with the number of standby elements (optimistically assuming that the sensing and switching products of the redundant configuration are working perfectly, and failed redundant components are replaced before their companion component fails).

A design team may often find that redundancy is a way to improve product reliability if time is of prime importance, if the products requiring redundancy are already designed and the products are known to be of poor reliability.

On the other hand, in weighing its advantages, the design team may find that redundancy will

- Prove too expensive, if the products and redundant sensors and switching products are costly
- Exceed the limitations on size and weight, particularly in avionics, missiles, and satellites
- Exceed the power limitations, particularly in active redundancy
- Attenuate the input signal, requiring additional amplifiers (which increase complexity)
- Require sensing and switching circuitry so complex as to offset the reliability advantage of redundancy

### **Protective Architectures**

It is generally desirable to include means in a design for preventing a product, structure, or interconnection from failing catastrophically, and instead allow it to fail safely.

Fuses and circuit breakers are examples used in electronic products to sense excessive current drain and disconnect power from a failed circuit. Fuses within circuits safeguard products against voltage transients or excessive power dissipation and protect power supplies from shorted parts. Thermostats may be used to sense critical temperature, limiting conditions and shutting down the product or a component of the system until the temperature returns to normal. In some products, self-checking circuitry can also be incorporated to sense abnormal conditions and operate adjusting means to restore normal conditions or activate switching means to compensate for the malfunction.

Protective architectures can be used to sense failure and protect against possible secondary effects. In other cases, means can be provided for preventing a failed product or structure from completely disabling the product. For example, a fuse or circuit breaker can disconnect a failed product from a product in such a way that it is possible to permit partial operation of the product after the failure, in preference to total product failure. By the same reasoning, degraded performance of a product after failure of a product is often preferable to complete stoppage. An example is the shutting down of a failed circuit whose design function is to provide precise trimming adjustment within a deadband of another control product. Acceptable performance may thus be permitted, perhaps under emergency conditions, with the deadband control product alone.

Sometimes the physical removal of a part from a product can harm or cause failure of another part of the product by affecting load, drive, bias, or control. In some cases, self-healing techniques can be employed to self-check and self-adjust to effect changes automatically to permit continued operation after a failure.

The ultimate design, in addition to its ability to act after a failure, would be capable of sensing and adjusting for drifts to avert failures.

In the use of protective techniques, the basic procedure is to take some form of action after an initial failure or malfunction, to provide perhaps reduced performance, and to prevent additional or secondary failures. Such techniques can be considered as enhancing product reliability, although they also affect availability and product effectiveness. No less a consideration is the impact of maintenance, repair, and product replacement. If a fuse protecting a circuit is replaced, what is the impact when the product is reenergized? What protective architectures are appropriate for postrepair operations? What maintenance guidance must be documented and followed when fail-safe protective architectures have or have not been included?

## Stress Margins

Products and structures should be designed to operate satisfactorily at the extremes of the parameter ranges, and allowable ranges must be included in the procurement or reprocurement specifications. To guard against out-of-tolerance failures, the design team must consider the combined effects of tolerances on products, subsequent changes due to the range of expected environmental conditions, drifts due to aging over the period of time specified in the reliability requirement, and tolerances in products used in future repair or maintenance functions.

Methods of dealing with product and structural parameter variations include statistical analysis and worst-case analysis. In statistical design analysis, a functional relationship is established between the output characteristics of the structure and the parameters of one or more of its products. In worst-case analysis, the effect that a product has on product output is evaluated on the basis of end-of-life performance values or out-of-specification replacement products.

## Derating

The principle of derating is that there are no distinct stress boundaries for voltage, current, temperature, power dissipation, etc. above which immediate failure can occur and below which the product will operate indefinitely. Instead, the life of some products increases in a continuous manner as the stress level is decreased below the rated value. Practically, however, there are minimum stress levels below which increased derating will lower reliability, and the complexity required to step up performance will offset any gain in reliability.

## Size and Weight Control

Methods to reduce product volume include:

- Eliminating unused space
- Selecting an exterior shape to require least possible volume when integrated with the intended installation structure
- Eliminating separable interconnections, using optimally shaped components and subassemblies
- Minimizing interconnection requirements
- Eliminating support components such as heat sinks, blowers, and special coolant flow passages
- Eliminating redundant components
- Using components and package elements to perform multiple functions

Methods to lower product weight include using high-strength lightweight materials, eliminating duplicate structures, and providing only that degree of strength required to reach a desired safety factor.

## Potential Failure Sites and Failure Mechanisms

The design team must evaluate the potential failure mechanisms, failure stresses, failure sites, and failure modes, given a product architecture, the comprising products and materials, and the manufacturing processes. One approach to evaluation consists of the assessment of a list of candidate or “potential” failure mechanisms. The load conditions that cause the failure mechanisms to occur are then determined in light of the life cycle usage environment identified earlier. [Table 11.6.1](#) presents various failure mechanisms and the associated load conditions.

Once the failure mechanisms and associated stresses have been identified, then failure sites are specified and a detailed reliability assessment is conducted for each location suspected to be a potential area of failure. [Table 11.6.2](#) presents an example case of various failure sites, mechanisms, and load structures for a microelectronic product.

Failures can be categorized by their impact on end product performance. A critical failure is an event that reduces the performance of the end product to unacceptable levels. A noncritical failure, also called a fault, does not reduce performance to unacceptable levels. Failures can also be classified by the time

TABLE 11.6.1 The Load Conditions which Cause Failure Mechanisms

Failure Mechanism	Containment	$\Delta T$ (Temperature Cycle Magnitude)	RH (Relative Humidity)	T (Steady-State Temperature)	Vibration/Shock	Maintenance and Handling	Voltage
Brittle fracture		X		X	X	X	
Ductile fracture				X	X		
Yield		X		X	X		
Buckling		X		X	X	X	
Large elastic deformation		X			X		
Interfacial deadhesion	X	X	X	X	X		
Fatigue crack initiation	X	X	X	X	X		
Wear					X		
Creep		X		X	X		
Corrosion	X		X	X		X	
Dendritic growth	X		X			X	X
Fatigue crack propagation		X			X	X	
Diffusion				X			X

TABLE 11.6.2 Example: Failure Sites, Operational Loads, and Failure Mechanisms for a Microelectronic Product

Site	Containment	$\Delta T$ (Temperature Cycle Magnitude)	RH (Relative Humidity)	T (Steady-State Temperature)	Vibration/Shock	Voltage	Maintenance and Handling
Die		A, L, G	I		A, L, G		
Die attach		A, F, L, G			A, L, G, C		
Flip-chip solder joints	I, K	L, G	I	B, C, I, N	L, G	M	
Tape automated bonds	I, J, K	L, G	I, J	A, B, I, J, M	L, G	M, J	
Wire	I	G, L	I		G, L, E		
Leads	I, J	L	I, J	I	D, L, H	L, J	D, G
Substrate		L, G			A, B, L, G		
Substrate attach		F, L, G			C, L, G		

Note: A — brittle fracture; B — ductile fracture; C — yield; D — buckling; E — large elastic deformation; F — interfacial deadhesion; G — fatigue crack initiation; H — wear; I — corrosion; J — dendritic growth; K — interdiffusion; L — fatigue crack propagation; M — diffusion.

frame and manner in which the event occurs. The categories are catastrophic, intermittent, out-of-tolerance, and maladjustment.

1. **Catastrophic failures.** A catastrophic failure occurs when a product becomes completely inoperative or exhibits a gross change in characteristics. Examples are an open or shorted resistor or capacitor, a leaky valve, a stuck relay, or a broken switch.
2. **Intermittent failures.** Intermittent failures are nonperiodic failures that can occur within products, interconnects, or product interfaces including software. Examples include switch bouncing and poor transmission of signals. The design team must not only safeguard against the effects of intermittent failures, but also avoid creating possible modes of such failures (e.g., conditions permitting product-to-product or structural breakdowns).
3. **Out-of-tolerance failures.** Out-of-tolerance failures result from degradation, deterioration, drift, and wearout. Examples are the drifting of resistor and capacitor values and the wearing out of relays and solenoid valves and precision gears. The changes can arise as a result of time, temperature or temperature cycles, humidity, altitude, etc. When these changes, considered collectively, reach the point where product performance is below acceptable limits, we say that the product has failed.
4. **Maladjustment failures.** Maladjustment failures are often due to human error. Failures arise from improper adjustment of products, as well as abuse of adjusting products due to lack of understanding of the adjustments and the capabilities of the products. Such failures are hard to evaluate and difficult to avoid but must be considered if the reliability of the product is to be sustained.

## Designing for the Application Environment

The design of modern products requires that the team be acquainted with the environmental factors affecting product performance over time. The environment is seldom forgiving and when a weak point exists, performance suffers. Design teams must understand the environment and its potential effects and then must select designs or materials that counteract these effects or provide methods to alter or control the environment within acceptable limits.

In addition, a product can create or perturb an environment. For example, many epoxies out-gas during cure, releasing corrosive or degrading volatiles or particulates into the product. Teflon may release fluorine and polyvinylchloride (PVC) may release chlorine. Certain solid rocket fuels are degraded into a jelly-like mass when exposed to aldehydes or ammonia, either of which can come from a phenolic nozzle cone. Common environmental considerations follow.

### Temperature Control

Temperature is a powerful agent for electrical, chemical, and physical deterioration for two basic reasons:

- The physical properties of almost all known materials are modified by changes in temperature, temperature gradients, and temperature extremes.
- The rate of most chemical reactions is influenced by the temperature of the reactants.

Nevertheless, the effects of steady-state temperature and spatial and temporal temperature gradients must be clearly understood before a thermal control method is determined. A good practice is to develop a table of potential failure sites and failure mechanisms and the effects of temperature in its many forms.

Poor heat removal of dissipated  $I^2R$  losses, hysteresis, or eddy current losses can result in physical damage or accelerated chemical reaction rates. The latter occurrence, affecting certain types of materials, can cause general degradation and catastrophic or intermittent failures. But the fault is not always with the design; air intakes or outlets could be blocked because of faulty installation, or maintenance personnel might fail to clear or replace air filters.

Thermal management schemes for electronic equipment are selected, once the heat flux and the maximum temperature difference available for heat transfer have been identified. A complete thermal

management strategy involves selecting an appropriate heat removal scheme for each level of packaging. For low heat fluxes, passive thermal management techniques can be used. Such techniques do not require the expenditure of external energy for the heat removal. Interest in such techniques is currently very strong, due to their design simplicity, low cost, and high reliability.

Examples of passive cooling techniques include conduction cooling using high thermal conductivity substrates and/or heat sinks and natural convection air cooling. Conduction cooling can be employed when the heat source is not directly exposed to the coolant. This method is desirable in dense electronic packages, where radiation and convection are not effective cooling means. Natural convection cooling relies on the buoyancy-induced flows generated due to heating. For a maximum temperature rise of 85°C above the environment, heat fluxes of up to about 0.1 W/cm<sup>2</sup> can be removed by natural convection air cooling under nominal sea-level environmental conditions.

For higher heat fluxes, a combination of passive and active techniques can sometimes be used. This may include, for example, a high thermal conductivity substrate at the board level, along with forced air cooling at the box level. For this range of heat fluxes, the use of cold plate technology, thermoelectrics, and flow-through cooling are also possible; other common techniques are the use of heat pipe or thermosyphon (see Chapter 4).

Besides the out-gassing of corrosive volatiles when subjected to heat, almost all known materials will expand or contract when their temperature is changed. This expansion and contraction causes problems with fit between product interface and interconnections. Local stress concentrations due to nonuniform temperature are especially damaging, because they can be so high. A familiar example is a hot water-glass that shatters when immersed in cold water. Metal structures, when subjected to cyclic heating and cooling, may ultimately collapse due to the induced stresses and fatigue caused by flexing. The thermocouple effect between the junction of two dissimilar metals causes an electric current that may induce electrolytic corrosion.

Plastics, natural fibers, leather, and both natural and synthetic rubber are all particularly sensitive to temperature extremes as evidenced by their brittleness at low temperatures and high degradation rates at high temperatures.

### **Shock and Vibration Control**

Shock and vibration can harmfully flex leads and interconnects, dislodge parts or foreign particles into bearings, pumps, and electronics, cause acoustical and electrical noise, and lead to structural instabilities. Protective measures against shock and vibration stresses are generally determined by an analysis of the deflections and mechanical stresses produced by these environmental factors. This generally involves the determination of natural frequencies and evaluation of the mechanical stresses within components and materials produced by the shock and vibration environment. If the mechanical stresses so produced are below the acceptable safe working stress of the materials involved, no direct protection methods are required. If, on the other hand, the stresses exceed the safe levels, corrective measures such as stiffening, reduction of inertia and bending moment effects, and incorporation of further support members are indicated. If such approaches do not reduce the stresses below the acceptable safe levels, further reduction is usually possible by the use of shock-absorbing mounts.

Products are sometimes specially mounted to counter the destructive effects of shock and vibration. Shock mounts often serve this purpose, but effective means for attenuating shock and vibration simultaneously are complex. Isolation of a product against the effects of vibration requires that the natural frequency of the product be substantially lower than the undesired frequency of vibration.

Three basic kinds of isolators are available:

- Elastomers made of natural or synthetic rubber, used in a shear mode or in a diaphragm to dampen the induced shock or vibration.
- Metallic isolators, such as springs, metal meshes, or wire rope. Springs lack good damping qualities, but meshes and rope provide smooth friction damping.

- Viscous dampers (similar to the type used on automobiles) which are velocity-sensitive, tend to become ineffective under high-frequency vibration. Resilient mounts must be used with caution, since they can amplify the intensity of shock and vibration if improperly placed. The ideal goal is to design a product to be resistant to shock and vibrations, rather than to provide complete isolation.

Another vibration protective technique is potting or encapsulation of small parts and assemblies. The potting material should be compliant enough to dampen vibrations. Some materials polymerize exothermically, and the self-generated heat may cause cracking of the casting or damage to heat-sensitive products. Another problem is shrinkage of the potting material. In some cases, molds are made oversized to compensate for shrinkage.

One factor that is not often considered is that the vibration of two adjacent components, or separately insulated subsystems, can cause a collision if maximum excursions and sympathetically induced vibrations are not accounted for in design. Another failure mode, fatigue (the tendency for a material to break under cyclic stress loads considerably below its tensile strength), includes high cycle fatigue, acoustic fatigue, and fatigue under combined stresses such as temperature extremes, temperature fluctuations, and corrosion.

In addition to using proper materials and configuration, it may still be necessary to control the amount of shock and vibration experienced by the product. Damping products are used to reduce peak oscillations and special stabilizers can be employed when unstable configurations are involved. Typical examples of dampeners are viscous hysteresis, friction, and air damping. Vibration isolators commonly are identified by their construction and material used for the resilient elements (rubber, coil spring, woven metal mesh, etc.). Shock isolators differ from vibration isolators in that shock requires a stiffer spring and a higher natural frequency for the resilient element. Some of the types of isolation mounting products are underneath, over-and-under, and inclined isolators. In some cases, however, even though an item is properly insulated and isolated against shock and vibration damage, repetitive forces may loosen the fastening products. If the fastening products loosen enough to permit additional movement, the product will be subjected to increased forces and may fail. Many specialized self-locking fasteners are commercially available.

### Chemical Action Control

The earth's environment contains numerous deteriorators including oxygen, carbon dioxide, nitrogen, snow, ice, sand, dust, salt water spray, organic matter, and chemicals in general. Product specifications often state limits on temperature, humidity, altitude, salt spray, fungus, sunshine, rain, sand, and dust.

A material or structure can chemically change in a number of ways. Among them are interactions with other materials (i.e., metal migration, diffusion) and modifications in the material itself (recrystallization, stress relaxation, phase changes, or changes induced by irradiation). In addition to the deterioration problems associated with the external environments to which products are subjected, adhesives, batteries, and certain types of capacitors are susceptible to chemical aging and biological growths.

Materials widely separated in the electromotive series are subject to galvanic action, which occurs when two dissimilar metals are in contact in a liquid medium. The most active metal dissolves, hydrogen is released, and an electric current flows from one metal to the other. Coatings of zinc are often applied to iron so that the zinc, which is more active, will dissolve and protect the iron (a process known as *galvanization*). Galvanic action is known to occur within the same piece of metal, if one portion of the metal is under stress and has a higher free-energy level than the other. The part under stress will dissolve if a suitable liquid medium is present. Stress-corrosion cracking occurs in certain magnesium alloys, stainless steels, brass, and aluminum alloys. It has also been found that a given metal will corrode much more rapidly under conditions of repeated stress than when no stress is applied.

Corrosion-resistant materials should be used as much as possible. Although aluminum is excellent in this respect due to the thin oxide coating that forms when it is exposed to the atmosphere, it tends to

pit in moist atmospheres. Furthermore, aluminum may corrode seriously in a salt-laden marine atmosphere. Either anodization or priming with zinc chromate can provide additional protection.

Magnesium is sometimes used to minimize the weight of products but must be protected by surface additives against corrosion and electrolytic reaction. A coating of zinc chromate serves both purposes. Because magnesium is the most reactive metal normally used for structural purposes, the grounding of the magnesium structure requires careful selection of another metal for making the connection. Zinc- or cadmium-plated steel are the more commonly chosen connective materials.

Copper, when pure, is quite resistant to corrosion. However, under certain conditions, copper-made products will become chemically unstable. Transformers have occasionally failed due to impurities in the insulation and moisture. These conditions favor electrolytic reaction, which causes the copper to dissolve and eventually results in an open circuit.

Iron and steel are used in many products and structures because of their good magnetic and structural properties; however, only certain stainless steels are reasonably resistant to corrosion. Various types of surface plating are often added, but since thin coatings are quite porous, undercoatings of another metal such as copper are often used as a moisture barrier. Cadmium and zinc plating in some marine environments corrode readily, and often grow “whiskers”, which can cause short circuits in an electronic product.

Proper design of a product therefore requires trade-offs in

- Selecting corrosion-resistant materials
- Specifying protective coatings if required
- Avoiding use of dissimilar metallic contacts
- Controlling metallurgical factors to prevent undue internal stress levels
- Preventing water entrapment
- Using high-temperature resistance coatings when necessary
- Controlling the environment through dehydration, rust inhibition, and electrolytic and galvanic protective techniques

### **Biological Growth Control**

High humidity and warm temperatures often favor the growth of fungus, which can lead to deterioration of many electrical and mechanical properties. Products designed for use under tropical conditions can receive a moisture- and fungus-proofing treatment, which consists of applying a moisture-resistant varnish containing a fungicide. Air-drying varnishes generally are not as moisture-proof as are the baked-on types. This treatment is usually quite effective, but the useful life of most fungicides is less than that of the varnish, and retreatments may be necessary.

### **Moisture Control**

Moisture, and impurities that may be contained with it, are known to cause corrosion of many metal systems. In addition, mated products can be locked together, especially when moisture condenses on them and then freezes. Similarly, many materials that are normally pliable at low temperatures become hard and brittle if moisture has been absorbed and subsequently freezes. Condensed moisture acts as a medium for the interaction between many, otherwise relatively inert, materials. Most gases readily dissolve in moisture. The volume increase from water freezing (i.e., converting from a fluid to solid state) can also physically separate components, materials or connections. The chlorine released by PVC plastic, for example, forms hydrochloric acid when combined with moisture.

Although the presence of moisture may cause deterioration, the absence of moisture also may cause reliability problems. The useful properties of many nonmetallic materials such as leather and paper, which become brittle and crack when they are very dry, depend upon an optimum level of moisture. Similarly, fabrics wear out at an increasing rate as moisture levels are lowered, and fibers become dry and brittle. Environmental dust can cause increased wear, friction, and clogged filters due to lack of moisture.

Moisture, in conjunction with other environmental factors, creates difficulties that may not be characteristic of the factors acting alone. For example, abrasive dust and grit, which would otherwise escape, can be trapped by moisture. The permeability (to water vapor) of some plastics (PVC, polystyrene, polyethylene, etc.) is related directly to their temperature. The growth of fungus is enhanced by moisture, as is the galvanic corrosion between dissimilar metals. Some design techniques that can be used separately or combined to counteract the effects of moisture are

- Elimination of moisture traps by providing drainage or air circulation
- Using desiccant products to remove moisture when air circulation or drainage is not possible
- Applying protective coatings
- Providing rounded edges to allow uniform coating of protective material
- Using materials resistant to moisture effects, fungus, corrosion, etc.
- Hermetically sealing components, gaskets, and other sealing products
- Impregnating or encapsulating materials with moisture-resistant waxes, plastics, or varnishes
- Separation of dissimilar metals or materials that might combine or react in the presence of moisture or of components that might damage protective coatings.

The design team also must consider possible adverse effects caused by specific methods of protection. Hermetic sealing, gaskets, protective coatings, etc. may, for example, aggravate moisture difficulties by sealing moisture inside or contributing to condensation. The gasket materials must be evaluated carefully for outgassing of corrosive volatiles or for incompatibility with adjoining surfaces or protective coatings.

### **Sand and Dust Protection**

In addition to the obvious effect of reduced visibility, sand and dust can degrade a product by abrasion leading to increased wear, friction causing both increased wear and heat, and clogging of filters, small apertures, and delicate products. Thus, products having moving parts require particular care when designing for sand and dust protection. Sand and dust will abrade optical surfaces, either by impact when being carried by air or by physical abrasion when the surfaces are improperly wiped during cleaning. Dust accumulations have an affinity for moisture and when combined may lead to corrosion or the growth of fungus.

In relatively dry regions, such as deserts, fine particles of dust and sand can readily be agitated into suspension in the air, where they may persist for many hours, sometimes reaching heights of several thousand feet. Thus, even though there is virtually no wind present, the speeds of vehicles or vehicle-transport product through these dust clouds can also cause surface abrasion by impact.

Although dust commonly is considered to be fine, dry particles of earth, it also may include minute particles of metals, combustion products, and solid chemical contaminants. These other forms may provide direct corrosion or fungal effects on products, because this dust may be alkaline, acidic, or microbiological.

When products require air circulation for cooling or removing moisture, the question is not whether to allow dust to enter, but rather how much or what size dust can be tolerated. The problem becomes one of filtering the air to remove dust particles above a specific nominal size. The nature of filters, however, is such that for a given working filter area, as the ability of the filter to stop increasingly smaller dust particles is increased, the flow of air or other fluid through the filter is decreased. Therefore, the filter surface area either must be increased, the flow of fluid through the filter decreased, or the allowable particle size increased (i.e., invariably, there must be a compromise). Interestingly enough, for aircraft engines, the amount of wear is proportional to the weight of ingested dust, but inversely proportional to dust size.

Sand and dust protection must be planned in conjunction with protective measures against other environmental factors. For example, it is not practical to specify a protective coating against moisture if sand and dust will be present, unless the coating is carefully chosen to resist abrasion and erosion or is self-healing.

## Explosion Control

Protection against explosion is both a safety and reliability problem. An item that randomly exhibits explosive tendencies is one that has undesirable design characteristics and spectacular failure modes. This type of functional termination, therefore, requires extreme care in design and reliability analyses.

Explosion protection planning must be directed to three categories (not necessarily mutually exclusive) of products:

- Items containing materials susceptible to explosion
- Components located near enough to cause the explosive items to explode
- Product that might be damaged or rendered temporarily inoperative by overpressure, flying debris, or heat from an explosion

The first category includes products containing flammable gases or liquids, suspensions of dust in the air, compounds that spontaneously decompose in certain environments, product containing or subjected to high or low extremes of pressure (includes implosions), or any other products capable of creating an explosive reaction. Keep in mind that even basically inert materials such as glass or metals can explode when subjected to rapid environmental changes or extremes such as temperature or stress.

The second category includes many variations on methods for providing an energy pulse, a catalyst, or a specific condition that might trigger an explosion. A nonexplosive component, for example, could create a corrosive atmosphere, mechanical puncture, or frictional wear on the side of a vessel containing a high-pressure and thereby cause the container to explode.

The third category is important because a potentially explosive product (such as a high-pressure air tank) can be damaged or made to explode from another explosion. Thus, some reasoning must be applied when considering products not defined by the first two categories. From a practical standpoint, explosion protection for items in the third category should be directed to product that might possibly be near explosions.

The possibility of an explosive atmosphere leaking or circulating into other product compartments must also be recognized. Lead-acid batteries, for example, create hydrogen gas that, if confined or leaked into a small enclosure, could be exploded by electrical arcing from motor brushes, by sparks from metallic impacts, or by exhaust gases. Explosive environments, such as dust-laden air, might be circulated by air distribution products. Dust from common ingredients such as wheat flour has been the source of massive, catastrophic explosions.

Explosion protection and safety are very important for design and reliability evaluations and must be closely coordinated and controlled. Just as a safe product is not necessarily reliable, neither is a reliable product necessarily safe; but the two can be compatible.

## Electromagnetic Radiation Control

Protection against the effect of electromagnetic radiation has become a sophisticated engineering field of electromagnetic compatibility design. The radiation environment in space near the earth is composed primarily of Van Allen, auroral, solar flare, and cosmic phenomena. Of lesser importance are solar wind, thermal energy atoms in space, neutrons, naturally occurring radon gas, albedo protons, plasma bremsstrahlung, and man-made nuclear sources. In the electromagnetic spectrum are gamma rays, X-rays, ultraviolet, and Lyman-alpha radiation. Damage near the surface of the earth is caused by the electromagnetic radiation in the wavelength range from approximately 0.15 to 5 m. This range includes the longer ultraviolet rays, visible light, and up to about the midpoint of the infrared band. The most direct approach to protection is to avoid the limited region in which high radiation levels are found. When exposure cannot be avoided, shielding and filtering are important protective measures. In other cases, material design changes or operating procedural changes must be instituted in order to provide protection.

## High Vacuum Control

In a high vacuum, materials with a high vapor pressure will sublime or evaporate rapidly, particularly at elevated temperatures. In some plastics, the loss of plasticizer by evaporation will cause cracking, shrinking, or increased brittleness. Metals such as magnesium, which would normally evaporate rapidly ( $1 \text{ g/cm}^2/\text{year}$  at  $250^\circ\text{C}$ ), can be protected by inorganic coatings with low vapor pressures.

In a high vacuum, adjoining solid surfaces can become cold-welded after losing adsorbed gases. Some form of lubrication is therefore necessary. Conventional oils and greases evaporate quickly. Graphite becomes unsatisfactory (actually an abrasive) because of the loss of absorbed water. However, thin films of soft metals, such as lead, silver, or gold, are effective lubricants in a high vacuum. Thin films of molybdenum disulfide are often sprayed over chrome or nickel plating, forming easily sheared layers. The film also releases sulfur at interfaces during sliding, performing the same function as water vapor does for graphite.

## Human Factors and Operability

Humans are active participants in the operating of many products, and can be traded as an external “stress.” Consequently, the interaction of humans with products must be weighed against safety, reliability, maintainability, and other product parameters to assess product reliability, maintainability time and performance, system and subsystem safety analyses, and specific human engineering design criteria. For convenience and clarity, four types of human interactions with a product are identified:

- Design and production of a product
- Operators and repairers as mechanical elements (human engineering)
- Operators and repairers as decision elements (human performance reliability)
- Bystanders (this classification is not considered further because it is largely a safety matter, unless they consciously or inadvertently operate or affect the operation of a product)

## Designing for Operability

While product design teams, planners, and managers would hope to have well-above-average people in every position associated with product operation, product design must accommodate the realities of the product’s life cycle use. The complexity of the product that is presented to the operator, the array of components, including ancillary product, cable connectors, patch panels, switches, knobs, controls, panel markings, meters, oscilloscopes, horns, bells, panel lights, etc., must be of concern in design. The various components comprising the product should be clearly labeled for easy identification. Those items that must be manipulated in order to connect the product (cable connectors, patch panels, switches) should be arranged in a simple and logical order and should be plainly marked. Typical constraints are that

- An operator should be within the physical capabilities of the complete range of potential operators.
- A person should not be required to do something that his or her coordination will not allow him or her to do.
- In times of psychological stress, people cannot easily use, read, and respond to controls and displays.

Mock-ups under realistic conditions are very helpful in uncovering potential problems early in the design process. For example, if a product must be used at night in extremely cold weather, have a person try to use it in a freezing, poorly lit room for several hours.

## Designing for Maintainability

Few operational products can be perfectly reliable while meeting other product trade-offs such as rust. Maintenance can thus be an important consideration in the long-term effectiveness of a product.

Maintainability is the probability that, when a specified maintenance action is initiated, a failed product will be restored to operable conditions in a specified downtime. Thus, design features that will expedite maintenance will enhance maintainability. Designing for maintainability means inclusion in the design of those features that can be conceived to assist the maintenance technician. Specific features include the degree of accessibility for product replacement, facilities for fault isolation, special tools or test-product requirements, the level of servicing skills required, servicing documentation requirements, and spare-part stocking requirements.

Critical rating factors include grouping of components by electrical function, use of integral fault indication for basic modules; components or functional assemblies removable without interruption of permanent electrical connections; elimination of tool requirements for mechanical disassembly; direct access to removable assemblies; products commonality; and identification of replaceable components.

In checking out a product, the maintenance technician must often also operate it. Therefore, the design considerations relating to operability are, in general, also applicable to maintainability. In addition, many design considerations relating to maintenance are more complex than those relating to operation.

The design team needs to consider how the product actually will be repaired in the field, perhaps under the pressures of understaffed maintenance crews, many of whom are inexperienced, or by field service personnel with limited knowledge about the product. The design team must always keep in mind that a product may be used and repaired by people who have other things in mind than “babying” the product. The design team must also realize the difference between what people will probably do and what the design team thinks they ought to do.

The design team, in acknowledging that a product could fail if not maintained, should provide means for ease of maintenance, ease of removal of a failed unit, trouble shooting, access to the failed unit, and repair or replacement. Such means, in addition to improving maintainability, will also improve reliability through the averting of subsequent failure due to human errors during maintenance. Many design details are important to the maintenance technician. A list of “Do’s” and “Don’ts” in designing for maintainability is presented in [Table 11.6.3](#).

**TABLE 11.6.3 Warning to Design Teams: Some Common Design Errors Affecting Maintainability**

---

Don't place products or maintenance structures (e.g., oil filter) where they cannot be removed without removal of the whole unit from its case or without first removing other products
Don't put an adjustment out of arm's reach
Don't neglect to provide enough room for the technician to get his or her gloved hand into the unit to make an adjustment
Don't screw subassemblies together in such a way that the maintenance technician cannot tell which screw holds what
Don't use chassis and cover plates that fall when the last screw is removed
Don't make sockets and connectors for modules of the same configuration so that the wrong unit can be installed
Don't provide access doors with numerous small screws or attachments
Don't use air filters that must be replaced frequently; don't place these filters so that it is necessary to shut down power and disassemble the product to reach them
Don't omit the guide from a screwdriver adjustment, so that while the technician is adjusting and watching a meter, the screwdriver slips out of the slot
Don't design frequent failure or highly adverse impact failure items in least accessible locations
Don't unnecessarily subject nonwear components to failure stress caused by maintenance actions

---

## The Design Team

During the entire period of design, reliability should be continuously monitored by the design team. The membership of the design team and the technical matters requiring their attention are shown in [Table 11.6.4](#). A generic guiding list is given in [Table 11.6.5](#).

**TABLE 11.6.4 Design Team**

Members	Technical Considerations
Project engineer	Products lists and application
Electrical, mechanical, chemical, manufacturing, and design representations	Tolerance studies
Management representatives	Environmental and operational effects
Maintenance and logistics representatives	Drift, aging, and end-of-life parameters
User community representatives	Regression or worst-case analysis
	Reliability analysis
	Trade-off studies
	Maintenance factors
	Test data
	Availability and affordability analysis

**TABLE 11.6.5 Design Reliability Check List Item**

Are the requirements for performance, application, environment, and maintainability and reliability established for each product, interface, and structure?
Are the best available methods for reducing the adverse effects of operational environments on critical structures being utilized?
Have normal modes of failure and the magnitude of each mode for each component or critical product have been identified as to root cause?
Has shelf life of products chosen for final design been determined?
Have limited-life products been identified and inspection and replacement requirements specified?
Have critical products that require special procurement, testing, and handling been identified?
Are effective safety factors being used in the application of products, interfaces, and structures?
Have studies been made considering variability and degradation of parameters of products and structures?
Have all vital adjustments been classified as to factory, preoperational, or operator types?
Have adjustments been minimized?
Have stability requirements of all products and structures associated with each adjustment been established?
Are similar plugs and connectors adequately protected against insertion in wrong socket?
Are malfunction-indicating products being used extensively?
Are self-monitoring or self-calibration products installed in major products where possible?
Are mechanical support structures adequate?
Is there a concentrated effort to make the developmental model as near to the production model as possible?
Have packaging and mechanical layout been designed to facilitate maintenance and to reduce maintenance costs and downtime?

## Summary

When a product is being designed, it is assumed that the required investment will be justified according to how well the product performs its intended function over time. This assumption cannot be justified when a product fails to perform upon demand or fails to perform repeatedly. It is not enough to show that a product can conduct a function but that it can do so repeatedly when needed by the product user.

The design of any product involves trade-offs, including, but not limited to, performance capability, size, weight cost, product maintenance activities, and other factors, depending upon the intended use. In cases where human life is at risk, reliability issues play a major role in design. However, it is equally important to ask how large can a safety factor be for a critical situation such as a spacecraft, where human life might be in jeopardy, yet weight is a governing element.

The demand for better performance over time, coupled with higher-life cycle costs and stricter legal liabilities, has made product reliability of great importance. As the attitude toward production of engineering products has changed, reliability has established itself as one of the key elements when designing and manufacturing a product. However, the application of reliability principles in the product design and manufacturing processes has not always kept pace with the evolution of highly complex and dynamic engineering products. The design team must understand reliability theory and techniques, in conjunction

with design and manufacturing processes as well as the scenario for use of the product. The goal is to provide a scientific basis for design decisions considering product effectiveness requirements and the scenario for use, create a product design that will satisfy those requirements, and document those design decisions for both the hardware product and the recommended support product for sustaining product effectiveness during the life of the product.

## 11.7 Design of Manufacturing Systems and Processes

---

*Leonard D. Albano*

### Design of Manufacturing Systems

Section 11.6 provides strategies for the design of products that meet the customer's needs, based on findings derived from market studies and product research and development. The success of such designs depends on the enterprise's ability to manufacture it, without compromising product performance or incurring noncompetitive production costs. Thus, the design of a manufacturing system must be done with a clear understanding of the functional requirements and physical design parameters for a product and an appreciation for the business goals and constraints.

The structure of a manufacturing system is hierarchical. At the highest level, there are two distinct subsystems: the *direct manufacturing operations* and the *indirect overhead functions*. The direct manufacturing operations consist of the employees and equipment needed to convert the input resource materials into the final desired products. The indirect overhead functions refer to the people, vendors, and capital that support and supervise the direct operations. At the lowest level, the manufacturing system is defined by many basic manufacturing operations, such as metal cutting and plastic forming, that are used to create specific part types (see Chapter 13).

Manufacturing systems can be classified in terms of the volume and variety of products produced. One possible classification scheme is as follows:

1. *Continuous flow processes*: high volume production of a single product type, such as sugar and oil refineries
2. *Assembly lines*: high volume production of a limited product variety; relies on standardized components and interchangeable parts; common system for automotive industry
3. *Batch processing*: relatively low volume production of multiple product types; concepts of group technology used to batch workpieces to increase efficiency of process routing; example applications include the manufacture of aircraft and heavy construction equipment
4. *Job shop*: low volume production of a variety of nonstandard parts; focuses on customized products; early reliance on craftsmen has shifted to cellular manufacturing systems in order to maximize flexibility and throughput

The design of a manufacturing system may be defined in terms of the concept of domains, as presented in Section 11.3, and the integration of three or more design fields; they are product design, organization design, and software design.

1. *Product design*: The design of the direct manufacturing operations is based on mapping the product's design parameters in the physical domain to process variables in the process domain.
2. *Organizational design*: The human and financial resources, which contribute to both direct operations and the indirect overhead, are provided to satisfy the goals and structure of the business organization.
3. *Software design*: Computer-based tools are easily available to control production and inventory levels, support information flow for decision-making, and automate manufacturing operations.

Several important advances in manufacturing can be identified from the above design model. *Concurrent engineering* refers to the integration of product design and manufacturing system design. This approach involves continuous mapping from the functional domain to the physical domain to the process domain. If the organizational structure changes to adapt to new customer needs, the single enterprise may be replaced by a highly flexible, virtual enterprise that pools resources from several qualified organizations for rapid response. This virtual enterprise corresponds to *agile manufacturing*. With a rationalized approach to system design, the role of the computers, information technology, robots, etc. can be better understood (see Chapter 13). Mitchell (1991) defines *computer-integrated manufacturing*

as “the use of computers to achieve an integrated flow of manufacturing activities, based on integrated information flow that links together all organizational activities.”

A designer may develop many different manufacturing systems that are technically feasible. The designer must have some basis for the selection of a system and the layout of the various elements that comprise it. The evaluation of economic feasibility is one criterion for decision-making. Economic feasibility depends on the planned production volume, fixed resources, total production costs, projected revenue stream, and the desired income. The latter case involves consideration of the investment strategy. Because of the interrelations among the system performance and the economic factors, the suggested design procedure is to consider economic feasibility as a design constraint. The ideal to be achieved is one involving the design and production of reliable products that satisfy the customer’s needs, while providing the desired profit and return on investment. See Chapter 13 for information on manufacturing system and enterprise management.

## **Manufacturing Process Design**

The principal objective of manufacturing process design is to produce an organized plan for converting raw materials into useful products. It involves the selection of timely and cost-effective methods to produce a product without compromising quality and reliability. As part of the product development process, good manufacturing process design contributes to the industrial competitiveness of a manufacturing enterprise, while poor process design contributes to cost and schedule overruns and the delivery of products that fail to meet some or all of the customers’ needs.

Manufacturing process planning often requires the consideration of several manufacturing processes for a specific part. In addition to considering manufacturing costs and production time, rational planning should also involve evaluation of how well a particular process satisfies the design requirements, which are delineated within the engineering drawings and reference specifications. The suitability of a given process may be based on many factors, such as

1. The dimensions and geometric precision that can be obtained
2. The surface roughness that can be attained
3. The changes that may be produced in material properties and part performance

Unfortunately, there is seldom much time to conduct an exhaustive laboratory or computer-based study and evaluation of all solution alternatives. A systematic approach to design that provides fundamental principles for decision-making would facilitate process design while enabling the designer to consider all important factors. Section 11.4, for instance, describes the concept of axiomatic design as a scientific framework for design and decision-making.

## **Metals Processing**

Metal shapes and components can be produced by various casting, forming, and metal-removal processes (see Chapter 13). In the case of metal removal, process planning involves selecting and sequencing the appropriate machine tools and operations so as to convert a solid piece part from its initial shape to a final, desired geometry. This involves matching machine and tool data to the design requirements, subject to certain constraints imposed by the manufacturing organization and facilities. In practice, it consists of five or more steps:

1. Interpretation of the engineering drawing and reference specifications
2. Selection of machining operations to form the specified surfaces
3. Selection of machine tools for each machining operation
4. Selection of jigs and fixtures to guide or facilitate machining
5. Sequencing the machining operations

The initial material shape may be one of any number of geometries, ranging from simple bar stock to a complex casting. Basic machine tool operations are discussed in Chapter 13, and they include shaping, planing, turning, grinding, sawing, and drilling.

Process planning is performed by either experienced planners or automated software systems. There are at least two major difficulties associated with relying solely on human planners. First, they often rely on intuition gained through experience, and this experience requires a significant period of time to accumulate. Consequently, the number of truly skilled planners in any given industry is limited from generation to generation. Second, the capacity of a manufacturing enterprise to adopt new processes and new systems is limited by the knowledge background and creativity of the process planner. In order to address these problems, computer-aided process planning (CAPP) systems (see Chapter 13) have been developed.

The two fundamental strategies for CAPP are the *variant approach* and the *generative approach*. The variant approach is closely related to the automation of manual process planning techniques, i.e., the process plan for a specific part is created by computer-based retrieval of an existing process plan from a data base. Thus, the role of the computer in a variant system is primarily to manage a data base of process knowledge. Generative systems synthesize manufacturing and planning knowledge to generate specific process plans for a specific part. The reasoning mechanism for generative systems varies from algorithms to decision trees to artificial intelligence techniques. The variant approach is the basis for the overwhelming majority of computer codes for process planning because of a number of practical computational advantages. Nevertheless, several generative systems have been developed by industry, and this area will continue to be the focus of research and development, especially for large companies that can support the considerable investment needed for software development and hardware procurement.

## Polymer Processing

There are basically two major categories of plastics: *thermoplastics* and *thermosetting resins* (see Chapter 12). Each group contains thousands of specific formulations with a wide range of mechanical, physical, and chemical properties. The scope of applications includes the automotive, houseware, and packaging industries. For example, government regulations pertaining to energy conservation have forced the automotive manufacturers to reduce the weight of automobiles. As a result, lightweight plastics have replaced traditional steel bumpers and outer panels while fulfilling specific performance requirements for mechanical strength, thermal resistance, and environmental durability.

To design with plastics, the product engineer selects an appropriate plastic material by considering a number of technical and economic factors in concert with specific data compiled in manufacturer's literature and encyclopedic data sources, such as the *Modern Plastics Encyclopedia*. To select the appropriate manufacturing process, the process engineer must understand the impact of the processing techniques on the material structure and, ultimately, the desired technical performance, e.g., mechanical strength and physical properties. Although a considerable number of plastic material alternatives are available, the variety of forming operations is limited. The basic set of processes includes compression molding, transfer molding, injection molding, extrusion, cold molding, thermoforming, and blow molding. The reader is referred to Chapter 13 for specific information on the production of thermoplastics and thermosetting resins.

Because of the interrelations between processing techniques and material structure, the axiomatic approach to design (see Section 11.4) provides helpful information for concurrent engineering. In this context, the use of plastic parts involves the successive mapping of engineering properties in the functional domain, to a plastic material structure in the physical domain, to processing techniques in the process domain. This mapping can be written in the form:

$$\{\mathbf{FRs}\} = [\mathbf{A}]\{\mathbf{DPs}\} \quad (11.7.1)$$

$$\{\mathbf{DPs}\} = [\mathbf{B}]\{\mathbf{PVs}\} \quad (11.7.2)$$

in which the desired material properties are contained in the vector of functional requirements  $\{\mathbf{FRs}\}$ , the material structure is described in  $\{\mathbf{DPs}\}$ , and the manufacturing process is defined by  $\{\mathbf{PVs}\}$ . Equations (11.7.1) and (11.7.2) display the general structure of the equations for materials design and process planning. The design matrices  $[\mathbf{A}]$  and  $[\mathbf{B}]$  are used to determine whether the proposed mapping satisfies the Independence Axiom: they must be either diagonal or triangular to allow for the manufacture of a plastic part with the desired properties (see Section 11.4.1, “The First Axiom: The Independence Axiom”). The production of microcellular plastics of MIT (Suh, 1990) is an example that illustrates design of a manufacturing process to yield the desired polymer structure.

## 11.8 Precision Machine Design

---

### *Alexander Slocum*

Any machine, from a machine tool to a photocopier to a camera, is an assembly of components that are designed to work together to achieve a desired level of performance. Each machine has a budget for cost and performance, and achieving the best balance between the two, regardless of the function of the machine, is the essence of *precision machine design*.

In order to be able to effectively develop a design for a precision machine, the design engineer must simultaneously envision in his/her head the functions the machine must perform (e.g., milling, turning, or grinding) alongside a pictorial library of component technologies (e.g., bearings, actuators, and sensors), generic machine configurations (e.g., cast or welded articulated and/or prismatic structures), analysis techniques (e.g., back-of-the-envelope and finite element methods), and manufacturing methods (e.g., machine, hand, or replication finished). In addition, the machine design engineer must be aware of the basic issues faced by the sensor and electronics engineer, the manufacturing engineer, the analyst, and the controls engineer. Only by a simultaneous consideration of all design factors can a viable and effective design be rapidly converged upon. Awareness of current technological limitations *in all fields* can also help a design engineer to develop new processes, machines, and/or components.

The goal of the precision machine design engineer is to make all the components of a precision machine in proper proportion of each other, both in relation to their physical size and the capabilities of the servocontroller and power systems. If a component is oversized, it may increase the cost of the machine while performance may not be increased. If a component is too small, the rest of the machine's components may never reach their potential and machine performance will suffer. Note that size is a function of static and dynamic qualifiers. Components that behave well statically do not necessarily have good dynamic performance.

In today's world where rapid time to market is essential, the design of quality precision machines depends on the ability of the design and the manufacturing engineers to predict how the machine will perform before it is built. Kinematics of a machine are easily tested for gross functionality using mechanism synthesis and analysis software. Wear rates, fatigue, and corrosion are often difficult to predict and control, but for the most part are understood problems in the context of machine tool design. Hence perhaps the most important factors affecting the quality of a machine are the accuracy, repeatability, and resolution of its components and the manner in which they are combined. These factors are critical because they affect every one of the parts that will be manufactured using the machine. Accordingly, minimizing machine cost and maximizing machine quality mandate predictability of accuracy, repeatability, and resolution. As noted by Donaldson\*: "A basic finding from our experience in dealing with machining accuracy is that machine tools are deterministic. By this we mean that machine tool errors obey cause-and-effect relationships, and do not vary randomly for no reason."

In this section, the design of precision machines will be studied by following a path of analysis of the overall system's potential for accuracy, as well as applying this perspective to the understanding of the operation of the components that make up a precision machine:

- Analysis of errors in a precision machine
- Structures
- Bearings

It is important to realize that the design of precision machines is like any other endeavor. The better one understands the fundamental principles and concepts, the better one will be able to integrate components into a precision system. In the light of understanding the science of design, one must always consider practical applied philosophy. A few broad design guidelines for the precision machine designer include:

---

\* Donaldson, R. November 1972. The deterministic approach to machining accuracy. *SME Fabricat. Technol. Symp.* Golden, CO (UCRL Preprint 74243).

- Subject all decisions to an “is there a better way” value analysis based on system considerations.
- Always picture in your mind how the system will be manufactured, assembled, used, and maintained.
- Minimize the number of parts in an assembly and minimize their complexity.
- Maximize the number of instances where reference surfaces and self-locating “snap together” parts can be used.
- Whenever possible, take advantage of kinematic design principles.
- Utilize new materials and technologies to their fullest potential.
- Read continuously and familiarize yourself with technologies in many areas.
- Observe continuously and familiarize yourself with products in many areas.

### Analysis of Errors in a Precision Machine

The first step in the design of a precision machine is to understand the basic definitions and principles that characterize and govern the design of all precision machines. Some of the more basic definitions and principles include

- The principle of reversal
- Modeling the errors in a machine
- Determination of the relative errors between the tool and the workpiece
- Linear motion system errors
- Estimating position errors from modular bearing catalog data
- Axis of rotation errors
- Error budgets

### Accuracy, Repeatability, and Resolution

There are three basic definitions to remember with respect to how well a machine tool can position its axes: *accuracy*, *repeatability (precision)*, and *resolution*. *Accuracy* is the maximum translational or rotational error between any two points in the machine’s work volume. *Repeatability (precision)* is the error between a number of successive attempts to move the machine to the same position, or the ability of the machine to make the same motion over and over. Bidirectional repeatability is the repeatability achieved when the point is approached from two different directions. This includes the effect of backlash in a leadscrew. Accuracy is often defined in terms of the mean, and repeatability in terms of the standard deviation. For a set of  $N$  data points with a normal (Gaussian) distribution, the mean  $x_{\text{mean}}$  and the standard deviation  $\sigma$  are defined as

$$x_{\text{mean}} = \frac{1}{N} \sum_{i=1}^N x_i \quad \sigma = \sqrt{\frac{1}{N-1} \sum_{i=1}^N (x_i - x_{\text{mean}})^2} \quad (11.8.1)$$

The standard deviation is used in the determination of the probability of occurrence of an event in a system that has a normal distribution. [Table 11.8.1](#) gives the percent chance of a value occurring within a number of standard deviations of its expected value.\* One must be very careful not to confuse an offset of the mean with the allowed random variation in a part dimension. For example, precision-molded plastic lenses for cameras have their molds hand finished to make the mean size of lenses produced equal to the nominal size required.

\* The equation for the computation of the percent chance was obtained from Drake, A. 1967. *Fundamentals of Applied Probability Theory*. McGraw-Hill, New York. p. 211. Values  $\phi(k)$  were computed using Mathematics™. Another valuable reference to have is Natrella, M. *Experimental Statistics*, NBS Handbook 91.

**TABLE 11.8.1 Chance of a Value Falling within  $k\sigma$  of its Expected Value**

<b>k</b>	<b>% chance of occurrence</b>
1.0	68.2689
2.0	95.4500
3.0	99.7300
4.0	99.9937
5.0	99.9999
6.0	100.0000

It is interesting to note, however, Bryan's\* observation of the issue of using probabilistic methods to characterize repeatability: "The probabilistic approach to a problem is only a tool to allow us to deal with variables that are too numerous, or expensive to sort out properly by common sense and good metrology." One must not belittle probability, however, for it is a mathematical tool like any other that is available to the design engineer. Required use of this tool, however, might be an indication that it is time to take a closer look at the system and see if the system can be changed to make it deterministic and therefore more controllable. Often the key to repeatability is not within the machine itself, but in isolating the machine from variations in the environment.\*\*

*Resolution* is the larger of the smallest programmable step or the smallest mechanical step the machine can make during point-to-point motion. Resolution is important because it gives a lower bound on the repeatability. When a machine's repeatable error is mapped, the resolution becomes important if the mapped errors are to be compensated for by other axes.

### Amplification of Angular Errors

Perhaps the most overlooked error in machine design is the amplification of an angular error over a distance to create a large translational error at some point in the machine. Mathematically, this error has a magnitude equal to the product of the distance between the point and the rotation source and the sine of the included angle. Hence this type of error can be referred to as a *sine error*. This principle extends to locating bearing surfaces far from the workpiece area of the machine tool.\*\*\* Errors in the bearing's motion can be amplified by the distance between the bearing and the workpiece, and can be transmitted to the workpiece. This can result in horizontal and vertical straightness errors and axial position errors. The same is true for the effects of all other types of errors on machine components. A *cosine error*, on the other hand, is the error made when the measurement of the distance between a point and a line is not made along a path orthogonal to the line.

With respect to dimensional measurements. In the late 1800s, Dr. Ernst Abbe noted "*If errors in parallax are to be avoided, the measuring system must be placed coaxially with the axis along which displacement is to be measured on the workpiece.*" The Abbe principle can be visualized by comparing measurements made with a dial caliper and a micrometer as shown in Figure 11.8.1. The dial caliper is often used around the shop because it is easy to use, the head slides back and forth to facilitate quick measurement. However, note that the measurement scale is located at the base of the jaws. When a part is measured near the tip of the jaws, the jaws can rock back slightly, owing to their elasticity and imperfections in the sliding jaw's bearing. This causes the caliper to yield a slightly undersize

\* Bryan, J. The Power of Deterministic Thinking in Machine Tool Accuracy, 1st Int. Mach. Tool Eng. Conf. November 1984. Tokyo (UCRL Preprint 91531).

\*\* "*In designing an experiment the agents and phenomena to be studied are marked off from all others and regarded as the field of investigation. All others are called disturbing agents. The experiment must be so arranged that the effects of disturbing agents on the phenomena to be investigated are as small as possible.*" James C. Maxwell.

\*\*\* See Bryan, J.B. 1989. The Abbe principle revisited — an updated interpretation, *Precis. Eng.* 1(3):129–132. An extension of the Abbe principle to this type of situation is referred to as the *Bryan principle*, which is discussed in Section 5.2.1 along with a discussion on where to mount sensors for various types of measurements.

**FIGURE 11.8.1** Abbe error illustrated through the use of a dial caliper and a micrometer.

measurement. The micrometer, on the other hand, uses a precision measuring device located in line with the part dimension, so there is no Abbe error. Both instruments are sensitive to how hard the jaws are closed on the part. A micrometer often has a torque limiting adjustment to provide a very repeatable measuring force. It is impossible to overstress the importance of Abbe errors.

The micrometer is more difficult to use and less versatile than the caliper, yet it has greater accuracy because of its more robust structural loop. So it is in the design of precision machines. Often one has to sacrifice ergonomics for performance. The goal, therefore, is to minimize the extent of the sacrifice.

### Sensitive Directions

It is important to note that there are *sensitive directions* in a machine, and it is along these directions that the most effort must be expended to minimize errors. For example, as illustrated in [Figure 11.8.2](#) an error motion  $\epsilon$  of a tool tangent to the surface of a round part of radius  $r$  in a lathe results in a radial error in the workpiece of magnitude  $\epsilon^2/r$ , which is much smaller than  $\epsilon$ . Sensitive directions can be *fixed*, such as when the tool is stationary and the part is moving (e.g., a lathe), or *rotating*, such as when the tool is rotating and the part is fixed (e.g., a jig borer).

**FIGURE 11.8.2** Illustration of sensitive directions.

### The Reversal Principle

How were the first accurate machines developed? Machines were first made repeatable, which can be done by paying special detail to surface finish of bearings, prevention of lost motion (e.g., backlash), and by making the forces on the machine repeatable. Once a machine is made repeatable, it can be used to measure the accuracy of another component or machine using the principle of reversal. This is illustrated in [Figure 11.8.3](#).

**FIGURE 11.8.3** Illustration of the principal of reversal.

The machine is used to measure a part from one side, obtaining a reading of

$$Z_{\text{probe before reversal}}(x) = \delta_{\text{CMM}}(x) - \delta_{\text{part}}(x)$$

The part is then turned over, taking care to keep its axial position justified, then the machine is used to remeasure the part, obtaining a reading of

$$Z_{\text{probe after reversal}}(x) = \delta_{\text{CMM}}(x) - \delta_{\text{part}}(x)$$

By subtracting the measurements from each other, the repeatable error in the measuring machine is removed:

$$\delta_{\text{part}}(x) = \frac{-Z_{\text{probe before reversal}}(x) + Z_{\text{probe after reversal}}(x)}{2}$$

There are many variations (e.g., for roundness measurements), and the principle shows how repeatability is often the most important characteristic of a precision machine. In fact, the principle can be applied to the design of the machine itself. For example, two bearing rails can be ground side by side, and then placed end to end on a machine. If the carriage that rides on them has the same bearing spacing as the individual rail length, then as the carriage moves on the end-to-end rails, it will not pitch or yaw, it will only have a straightness error. This straightness error can then be more readily compensated for by the motion of an orthogonal axis via an error compensation algorithm in the controller.

**Modeling the Errors in a Machine**

In order to determine the effects of a component’s error on the position of the toolpoint or the workpiece, the spatial relationship between the two must be defined. Figure 11.8.4 illustrates the issue: the tool is connected to the workpiece through the linkage that is the machine. Any errors between the machine’s links create error between the tool and the workpiece. The essential goal of precision machine design is to be able to model and predict these errors, so they can be addressed during the design state of the machine.

**FIGURE 11.8.4** The goal is to be able to model the errors in the machine to predict the error between the tool and the work during the design phase so appropriate action can be taken before the machine is built.

To represent the relative position of a rigid body in three-dimensional space with respect to a given coordinate system, a  $4 \times 4$  matrix is needed. This matrix represents the coordinate transformation to the reference coordinate system ( $X_R Y_R Z_R$ ) from that of the rigid body frame ( $X_n Y_n Z_n$ ), and it is called the *homogeneous transformation matrix* (HTM).<sup>\*</sup> The first three columns of the HTM are direction cosines (unit vectors  $i, j, k$ ) representing the orientation of the rigid body's  $X_n, Y_n,$  and  $Z_n$  axes with respect to the reference coordinate frame, and their scale factors are zero. The last column represents the position of the rigid body's coordinate system's origin with respect to the reference coordinate frame.  $P_s$  is a scale factor, which is usually set to unity to help avoid confusion. The presubscript represents the reference frame you want the result to be represented in, and the postsubscript represents the reference frame from which you are transferring:

$$R_{T_n} = \begin{bmatrix} O_{ix} & O_{iy} & O_{iz} & P_x \\ O_{jx} & O_{jy} & O_{jz} & P_y \\ O_{kx} & O_{ky} & O_{kz} & P_z \\ 0 & 0 & 0 & P_s \end{bmatrix} \quad (11.8.2)$$

Thus, the equivalent coordinates of a point in a coordinate frame  $n$ , with respect to a reference frame  $R$ , are

$$\begin{bmatrix} X_R \\ Y_R \\ Z_R \\ 1 \end{bmatrix} = R_{T_n} \begin{bmatrix} X_n \\ Y_n \\ Z_n \\ 1 \end{bmatrix} \quad (11.8.3)$$

For example, if the  $X_1 Y_1 Z_1$  coordinate system is translated by an amount  $x$  along the  $X$  axis, the HTM that transforms the coordinates of a point in the  $X_1 Y_1 Z_1$  coordinate frame into the  $XYZ$  reference frame is

$$XYZ_{T_{x_1 y_1 z_1}} = \begin{bmatrix} 1 & 0 & 0 & x \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11.8.4)$$

If the  $X_1 Y_1 Z_1$  coordinate system is rotated by an amount  $\theta_x$  about the  $X$  axis, the HTM that transforms the coordinates of a point in the  $X_1 Y_1 Z_1$  coordinate frame into the  $XYZ$  frame is

$$XYZ_{T_{x_1 y_1 z_1}} = \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & \cos\theta_x & -\sin\theta_x & 0 \\ 0 & \sin\theta_x & \cos\theta_x & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11.8.5)$$

Machine structures can be decomposed into a series of coordinate transformation matrices describing the relative position of each axis and any intermediate coordinate frames that may assist in the modeling

---

<sup>\*</sup> The HTM representation of structures has existed for many decades. See, for example, Denavit, J. and Hartenberg, R. June 1955. A kinematic notation for lower-pair mechanisms based on matrices. *J. Appl. Mech.* Perhaps the most often referenced work with respect to its application to manufacturing tools is Paul, R. 1981. *Robot Manipulators: Mathematics, Programming, and Control*. MIT Press, Cambridge, MA.

process, starting at the tip and working all the way down to the base reference coordinate system ( $n = 0$ ). If  $N$  rigid bodies are connected in series and the relative HTMs between connecting axes are known, the position of the tip ( $N$ th axis) in terms of the reference coordinate system will be the sequential product of all the HTMs:

$${}^R\mathbf{T}_N = \prod_{m=1}^N {}^{m-1}\mathbf{T}_m = {}^0\mathbf{T}_1 {}^1\mathbf{T}_2 {}^2\mathbf{T}_3 \dots \tag{11.8.6}$$

It can be difficult to determine how a part modeled as a rigid body actually moves; thus care must be taken when evaluating the error terms in the HTMs of systems with multiple contact points. Nonserial link machines (e.g., a four-bar linkage robot) require a customized formulation to account for interaction of the links.

**Determination of the Relative Errors Between the Tool and the Workpiece**

Ideally, the HTM products (Equation 11.8.6) for the position of the point on the workpiece the tool contacts and the location of the toolpoint with respect to the reference frame will be identical. The relative error HTM  $\mathbf{E}_{rel}$ , representing position and orientation errors between the tool and workpiece, is determined for  ${}^R\mathbf{T}_{work} = {}^R\mathbf{T}_{tool}\mathbf{E}_{rel}$ :

$$\mathbf{E}_{rel} = {}^R\mathbf{T}_{tool}^{-1} {}^R\mathbf{T}_{work} \tag{11.8.7}$$

The relative error HTM is the transformation in the toolpoint coordinate system that must be done to the tool in order to be at the proper position on the workpiece. For implementation of error correction algorithms on numerically controlled machines, as illustrated in Figure 11.8.5 one must consider how the axes will be required to move in order to create the desired motion, specified by Equation 11.8.7 in the tool reference frame. For the general case of a machine with revolute and translational axes (e.g., a five-axis machining center), one would have to use inverse kinematic solutions such as those developed for robot motion path planning. Most machine tools and CMMs have only translational axes, and thus the error correction vector  ${}^R\mathbf{P}_{correction}$  with respect to the reference coordinate frame can be obtained from

$${}^R \begin{bmatrix} P_x \\ P_y \\ P_z \end{bmatrix}_{correction} = {}^R \begin{bmatrix} P_x \\ P_y \\ P_z \end{bmatrix}_{work} - {}^R \begin{bmatrix} P_x \\ P_y \\ P_z \end{bmatrix}_{tool} \tag{11.8.8}$$

Because of Abbe offsets and angular orientation errors of the axes,  ${}^R\mathbf{P}_{correction}$  will not necessarily be equal to the position vector  $\mathbf{P}$  component of  $\mathbf{E}_{rel}$ .  ${}^R\mathbf{P}_{correction}$  does represent the incremental motions the X, Y, and Z axes must make on a Cartesian machine in order to compensate for toolpoint location errors.

**FIGURE 11.8.5** Repeatable error motions in one axis can be mapped and compensated for by motion of an orthogonal axis.

Compensating for errors in a machine can be a good thing; however, electronic compensation can only do so much. One has to start with a good design. The error in a machine can be minimized in general by maximizing the efficiency of the machine's *structural loop*. The structural loop is defined as the structure that joins the tool to the fixture to which the workpiece is attached. During cutting operations, the contact between the tool and workpiece can change the structural loop's characteristics. Maximizing the efficiency of the structural loop generally requires minimizing the path length of the mechanism. As can be seen from Abbe's principle or the HTM analysis method, the shorter the path length, the less the error amplification and the total end point error.

### Linear Motion System Errors

Consider the case of an ideal linear motion carriage shown in Figure 11.8.6 with  $x$ ,  $y$ , and  $z$  offsets of  $a$ ,  $b$ , and  $c$ , respectively. All rigid bodies have three rotational ( $\epsilon_x$ ,  $\epsilon_y$ ,  $\epsilon_z$ ) and three translational ( $\delta_x$ ,  $\delta_y$ ,  $\delta_z$ ) error components associated with their motion. These errors can be defined as occurring about and along the reference coordinate system's axes, respectively. Often the errors will be a function of the position of the body in the reference frame.

**FIGURE 11.8.6** Motion and errors in a single-axis linear motion carriage (prismatic joint).

For the linear carriage, the HTM (see Equation (11.8.2)) that describes the effects of errors on carriage motion can be obtained in the following manner. Observing the right-hand rule, a rotation  $\epsilon_x$ , about the  $X$  axis (*roll*) causes the tip of the  $Y$ -axis vector to move in the positive  $Z$  direction by an amount proportional to  $\sin \epsilon_x$ , and in the negative  $Y$  direction by an amount proportional to  $1 - \cos \epsilon_x$ . Since the error terms are very small, at most on the order of minutes of arc, small-angle approximations are valid and will be used. Hence the element  $o_{ky} = \epsilon_x$ . The roll error  $\epsilon_x$  also causes the tip of the  $Z$ -axis vector to move in the negative  $Y$  direction, so that the element  $o_{jz} = -\epsilon_x$ . A rotation  $\epsilon_y$  about the  $Y$  axis (*yaw*) causes the tip of the  $X$ -axis vector to move in the negative  $Z$  direction, so that  $o_{kx} = -\epsilon_y$ , and causes the tip of the  $Z$ -axis vector to move in the positive  $X$  direction, so  $o_{iz} = \epsilon_y$ . Similarly, a rotation  $\epsilon_z$  about the  $Z$  axis (*pitch*) causes the tip of the  $X$ -axis vector to move in the positive  $Y$  direction, so  $o_{jx} = \epsilon_z$ , and causes the tip of the  $Y$  axis vector to move in the negative  $X$  direction so that  $o_{iy} = -\epsilon_z$ . Translational errors  $\delta_x$ ,  $\delta_y$ , and  $\delta_z$  directly affect their respective axes, but care must be taken in defining them. Having neglected second-order terms, the HTM for the linear motion carriage with errors is

$${}^R\mathbf{T}_{\text{herr}} = \begin{bmatrix} 1 & -\epsilon_z & \epsilon_y & a + \delta_x \\ \epsilon_z & 1 & -\epsilon_x & b + \delta_y \\ -\epsilon_y & \epsilon_x & 1 & c + \delta_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11.8.9)$$

### Estimating Position Errors from Modular Bearing Catalog Data

The HTM method is powerful, but from where does one get estimates of the errors? For the linear motion system, the HTM assumes that the errors occur at the center of stiffness of the carriage. The *center of stiffness* is the point at which, when a force is applied to the system, no net angular motion results. For a symmetrical system, it is located at the center of the system. For other systems, the center of stiffness can be found in the same way that the *center of mass* is found:

$$x_{\text{center of stiffness}} = \frac{\sum_{i=1}^N K_i x_i}{\sum_{i=1}^N K_i} \quad (11.8.10)$$

Indeed, the *center of friction* can also be defined, and when locating the point, where the actuation force of an axis is to be applied, one can see that ideally, the center of mass, the center of stiffness, and the center of friction should all be coincident. In the best case, they will also be concurrent with external loads applied to an axis.

Once the center of stiffness has been found, the error motions about the center of stiffness can be determined using the dimensions of the system and estimates for the errors in individual bearing elements (e.g., linear ball bearing catalogs often include data on the vertical and horizontal error motions that will occur between the bearing block and the rail). Figure 11.8.7 illustrates the model of a linear motion system supported by modular bearings.

It can be assumed that the translational errors are based on the average of the straightness errors experienced by the bearing blocks:

$$\begin{aligned} \delta_x &= \delta_{\text{servo}} \\ \delta_y &= \frac{\delta_{y1} + \delta_{y2} + \delta_{y3} + \delta_{y4}}{4} \\ \delta_z &= \frac{\delta_{z1} + \delta_{z2} + \delta_{z3} + \delta_{z4}}{4} \end{aligned} \quad (11.8.11)$$

The angular errors are based on the differences in the average straightness errors experienced by pairs of bearing blocks acting across the carriage:

$$\begin{aligned} \epsilon_x &= \frac{\frac{(\delta_{y2} + \delta_{y3})}{2} - \frac{(\delta_{y1} + \delta_{y4})}{2}}{W} \\ \epsilon_y &= \frac{\frac{(\delta_{z3} + \delta_{z4})}{2} - \frac{(\delta_{z1} + \delta_{z2})}{2}}{L} \\ \epsilon_z &= \frac{\frac{(\delta_{y1} + \delta_{y2})}{2} - \frac{(\delta_{y3} + \delta_{y4})}{2}}{L} \end{aligned} \quad (11.8.12)$$

**FIGURE 11.8.7** A linear motion system will have errors that act about the center of stiffness of the system.

When the bearing blocks are moving in unison to create the straightness error, they would not be creating the angular errors. However, to be conservative when modeling the errors in a machine, since it cannot be known which errors are going to occur, one should simultaneously incorporate both translational and angular error estimates into the error model of the machine.

Once a machine has been built, the error motions would be measured and analyzed to verify whether the machine meets its performance criteria. This is also a good time to evaluate the effectiveness of the model. For example, [Figure 11.8.8](#) shows the straightness measurements for a linear motion axis supported by cam followers running on a vee and a flat. It is very difficult to tell what the source of the error is. [Figure 11.8.9](#) shows a Fast Fourier Transform of the straightness data. Note that the FFT is plotted in terms of amplitude and wavelength (as opposed to the more commonly seen power and frequency plots used by electrical engineers). It can help identify the dominant sources of error, so design attention can be properly allocated. It can also show, as in this case, that the errors from a number of different sources are of similar magnitude, so if greater performance is required, one should probably seek an alternate design.

### Axis of Rotation Errors\*

Consider the rotating body shown in [Figure 11.8.10](#). Ideally, the body rotates about its axis of rotation without any errors; however, in reality the axis of rotation revolves around an axis of the reference coordinate frame with radial errors  $\delta_x$  and  $\delta_y$ , an axial error  $\delta_z$ , and tilt errors  $\epsilon_x$  and  $\epsilon_y$ . All of these errors may be a function of the rotation angle  $\theta_z$ . For a point in the spindle coordinate frame  $X_n Y_n Z_n$ ,

\* Definitions used in this section were condensed from those provided in *Axis of Rotation: Methods for Specifying and Testing*. ANSI Standard B89.3.4M-1985, American Society of Mechanical Engineers, United Engineering Center, 345 East 47th Street, New York, NY 10017. This document also contains appendices which describe measurement techniques and other useful topics pertaining to axes of rotation.

FIGURE 11.8.8 Straightness of a linear motion system.

FIGURE 11.8.9 Fourier transform of the straightness of a linear motion system.

one would first use the rotation angle  $\theta_z$  to transform the point roughly the reference frame. Then, since the other error motions are small, the order of multiplication of their HTMs would not be critical.

With the operators  $S = \text{sine}$  and  $C = \text{cosine}$ , the general result is

$${}^R\mathbf{T}_{\text{nerr}} = \begin{bmatrix} C\epsilon_y C\theta_z & -C\epsilon_y S\theta_z & S\epsilon_y & \delta_x \\ S\epsilon_x S\epsilon_y C\theta_z & C\epsilon_x C\theta_z - S\epsilon_x S\epsilon_y S\theta_z & -S\epsilon_y C\epsilon_y & \delta_y \\ -C\epsilon_x S\epsilon_y C\theta_z + S\epsilon_x S\theta_z & S\epsilon_x C\theta_z + C\epsilon_x S\epsilon_y S\theta_z & C\epsilon_x C\epsilon_y & \delta_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11.8.13)$$

Note that this general result may also be used for the case of a linear motion carriage if  $\epsilon_z$  is substituted for  $\theta_z$ . Most often, second-order terms such as  $\epsilon_x\epsilon_y$  are negligible and small-angle approximations (i.e.,  $\cos \epsilon = 1$ ,  $\sin \epsilon = \epsilon$ ) can be used, which leads to

$${}^R\mathbf{T}_{\text{nerr}} = \begin{bmatrix} \cos\theta_z & -\sin\theta_z & \epsilon_y & \delta_x \\ \sin\theta_z & \cos\theta_z & -\epsilon_x & \delta_y \\ \epsilon_x \sin\theta_z - \epsilon_y \cos\theta_z & \epsilon_x \cos\theta_z + \epsilon_y \sin\theta_z & 1 & \delta_z \\ 0 & 0 & 0 & 1 \end{bmatrix} \quad (11.8.14)$$

**FIGURE 11.8.10** Motion and errors about an axis of rotation (revolute joint).

However, since this matrix is usually evaluated using a spreadsheet, it is best to use the exact form. When nanometer performance levels are sought, second-order effects can start to become important.

In the context of evaluating errors of rotating bodies, particularly when making measurements and discussing the results, it is necessary to consult the axis of rotation standard ANSI B89.3.4M. The “*error motion* of a spindle is the change in position, relative to the reference coordinate axes, of the surface of a perfect workpiece with its center line coincident with the axis of rotation.” This definition excludes thermal drift errors. The *runout* is the total displacement measured by an instrument sensing against a moving surface or moved with respect to a fixed surface. The term total indicator reading (TIR) is equivalent to runout. Unfortunately, all too often an imperfect workpiece is eccentrically mounted to a spindle and used to evaluate the performance of a spindle; hence the runout can be a misleading measurement. The “*axial motion* is the error motion colinear with the Z reference axis.” “Axial slip”, “end camming”, and “drunkenness” are nonpreferred terms which have been used in the past. The *tilt motion* is the error motion in an angular direction relative to the Z reference axis. Tilt motion creates sine errors on the spindle which is why the radial error motion is a function of Z position and face motion is a function of radius. Note that “coning”, “wobble”, and “swash” are sometimes used to describe tilt motion, but they are nonpreferred terms.

These errors are measured and then plotted using polar plots. The *error motion polar plot* is a polar plot of error motion made in synchronization with the rotation of the spindle. Error motion polar plots are often decomposed into plots of various error components. Some of the various types of error motion polar plots are shown in Figure 11.8.11. The *total error motion polar plot* is the complete error motion polar plot as recorded. The *average error motion polar plot* is the mean contour of the total error motion polar plot averaged over the number of revolutions. Note that asynchronous error motion components do not always average out to zero, so the average error motion polar plot may still contain asynchronous components. The average error motion value is a measure of the best roundness that can be obtained for a part machined while being held in the spindle (or the roundness of a hole the spindle is used to bore). The *fundamental error motion polar plot* is the best-fit reference circle fitted to the average error motion polar plots. The *residual error motion polar plot* is the deviation of the average error motion polar plot from the fundamental error motion polar plot. For radial error motion measurements, this represents the sum of the error motion and the workpiece (e.g., ball) out-of-roundness. The workpiece out-of-roundness can be removed using a reversal technique.\* The *asynchronous error motion polar plot* is the deviation of the total error motion polar plot from the average error motion polar plot. Asynchronous in this context means that the deviations are not repetitive from revolution to revolution. Asynchronous

\* The former was developed by Bob Donaldson at LLNL, and the latter by Spragg and Whitehouse. See Appendix B of ANSI B89.3.4M-1985 and the various cited references. Also see the ANSI standard *Measurement of Out-of-Roundness*, ANSI B89.3.1-1972(R1979).

**FIGURE 11.8.11** Examples of error motion and error motion component polar plots.

error motions are not necessarily random (in the statistical sense), but they do provide an indication of the attainable surface finish of the part.

Once again, the FFT is a vital tool for identifying the source of errors so that the designer can seek to minimize them. [Figure 11.8.12](#) shows an FFT of a grinding spindle’s error motion. The spindle speed was 1680 rpm (28 Hz), the bearing inner diameter was 75 mm, the outer diameter was 105 mm, the number of balls was 20, and the ball diameter was 10 mm. One of the dominant errors occurs at twice the rotation frequency, indicating that the bore in which the bearing is placed is most likely out-of-round.

**FIGURE 11.8.12** FFT of grinding spindle error motion.

## Error Budgets

To define the relative position of one rigid body with respect to another, six degrees of freedom must be specified. To further complicate matters, error in each of the six degrees of freedom can have numerous contributing components. In fact, considering all the interacting elements in a typical machine tool, the number of errors that must be kept track of can be mindboggling. Therefore, the best way to keep track of and allocate allowable values for these errors is to use an *error budget*. An error budget, like any other budget, allocates resources (allowable amounts of error) among a machine's different components.\* The goal is to allocate errors such that the ability of any particular component to meet its error allocation is not exceeded.

An error budget is formulated based on connectivity rules that define the behavior of a machine's components and their interfaces, and combinational rules that describe how errors of different types are to be combined. The first step in developing an error budget is to develop a kinematic model of the proposed system in the form of a series of homogeneous transformation matrices (HTM). The next step is to analyze systematically each type of error that can occur in the system and use the HTM model to help determine the effect of the errors on the toolpoint position accuracy with respect to the workpiece. The result is a list of all end point error components, their sources, and amplification-at-the-toolpoint factors (called the *error gains* or *sensitivities*). Different combinational rules can then be applied to yield upper and lower bound estimates of the total error in the machine.

Perhaps the most important step in assembling the error budget for a machine is the placement of the coordinate frames and the assignment of linear and angular errors corresponding to the axes. Angular motion errors suffer no ambiguity in their definition since they are unaffected by other errors and therefore can be defined with respect to any set of axes. Linear motion errors, on the other hand, must be carefully defined in terms of linear motion caused directly and linear motion that is the result of an Abbe error. During the design phase, the coordinate systems must be located at the origin of the angular errors, where pitch, yaw, and roll errors are the center of stiffness as defined above.

## Combinational Rules for Errors

Different types of errors do not mix unless handled properly. Once all error components are multiplied by their respective error gains, a final combination of errors can then be made to yield an educated guess as to the machine's expected performance. There are three common types of errors, which are defined as:\*\*

1. "*Random* — which, under apparently equal conditions at a given position, does not always have the same value, and can only be expressed statistically."
2. "*Systematic* — which always have the same value and sign at a given position and under given circumstances. (Wherever systematic errors have been established, they may be used for correcting the value measured.)" Systematic errors can generally be correlated with position along an axis and can be corrected if the relative accompanying random error is small enough.
3. "*Hysteresis* — is a systematic error (which in this instance is separated out for convenience). It is usually reproducible, has a sign depending on the direction of approach, and a value partly dependent on the travel. (Hysteresis errors may be used for correcting the measured value if the direction of approach is known and an adequate pretravel is made.)" Backlash is a type of hysteresis error that can be compensated for to the extent that is repeatable.

Systematic and hysteresis errors can often be compensated for to a certain degree using calibration techniques. Random error cannot be compensated for without real-time measurement and feedback into a correcting servoloop. Thus, when evaluating the error budget for a machine, three distinct *subbudgets*

---

\* See Donaldson, R. Error budgets. In *Technology of Machine Tools*, Vol. 5. *Machine Tool Accuracy*, R.J. Hocken, (ed.), Machine Tool Task Force.

\*\* These definitions are from the CIRP Scientific Committee for Metrology and Interchangeability, 1978. A proposal for defining and specifying the dimensional uncertainty of multiaxis measuring machines. *Ann. CIRP* 27(2):623–630.

based on systematic, hysteresis, and random errors should be kept. Often inputs for the error budget are obtained from manufacturers' catalogs (e.g., straightness of linear bearings), and they represent the peak-to-valley amplitude errors  $\epsilon_{pv}$ . A peak-to-valley error's equivalent random error with uniform probability of occurrence is given by  $\epsilon_{equiv, random} = \epsilon_{pv}/K_{pv}$ . If the error is Gaussian, then  $K_{pvrms} = 4$  and there is a 99.9937% probability that the peak-to-valley error will not exceed four times the equivalent random error.

In the systematic subbudget, errors are added together and sign is preserved so cancellation may sometimes occur. The same is true for the hysteresis subbudget. In the random subbudget, both the sum and the root-mean-square error should be considered, where the latter is given by

$$\epsilon_{irms} = \left( \frac{1}{N} \sum_{i=1}^N \epsilon_{irandom}^2 \right)^{1/2} \quad (11.8.15)$$

Note that in the random subbudget, all the random errors are taken as the  $1\sigma$  values. For the final combination of errors, the  $4\sigma$  value is typically used, which means that there is a 99.9937% chance that the random error component will not exceed the  $4\sigma$  value. In this case the total worst-case error for the machine will be

$$\epsilon_{iworst\ case} = \sum \epsilon_{isystematic} + \sum \epsilon_{ihysteresis} + 4 \sum \epsilon_{irandom} \quad (11.8.16)$$

The best-case error for the machine will probably be

$$\epsilon_{ibest\ case} = \sum \epsilon_{isystematic} + \sum \epsilon_{ihysteresis} + 4 \left( \sum \epsilon_{irandom}^2 \right)^{1/2} \quad (11.8.17)$$

In practice, the average of these two values is often used as an estimate of the accuracy the design is likely to achieve.

### Type of Errors

There are many types of errors that occur in a machine including:

**Straightness.** *Straightness* is the deviation from true straight-line motion. One generally thinks of the straightness error as primarily dependent on the overall geometry of the machine and applied loads. As shown in [Figure 11.8.13](#) straightness error can be considered the deviation from a straight line motion along a linear axis. The unofficial term *smoothness* can be used to describe straightness errors that are dependent on the surface finish of the parts in contact, the type of bearing used, and the bearing preload. In other words, the smoothness of motion would be the deviation from the best-fit polynomial describing the straightness of motion. Smoothness is not intended to be a descriptor of surface finish, but rather a descriptor of high-frequency straightness errors whose wavelength is typically on the order of the magnitude of the error, normal to the surface of two moving bodies in contact.

**Kinematic Errors.** Kinematic errors are defined here as *errors in the trajectory of an axis that are caused by misaligned or improperly sized components*. For example, kinematic errors include orthogonality (squareness or perpendicularity) and parallelism of axes with respect to their ideal locations and each other. Translational errors in the spatial position of axes are also a form of kinematic error. The dimensions of an axis's components can also cause the tool or workpiece to be offset from where it is supposed to be and is also classified as a kinematic error.

As shown in [Figure 11.8.14](#) given two machine axes of motion in the XZ plane with one machine axis aligned with the X reference axis, the orthogonality error is defined as the deviation  $\epsilon_y$  from  $90^\circ$  between the machine's other axis and the reference X axis. This is a straightforward definition which is simple to specify on a drawing, but is not necessarily simple to measure or control in production. Parallelism between two axes has horizontal and vertical forms that define the relative taper and twist

FIGURE 11.8.13 Straightness errors caused by surface form and finish errors.

FIGURE 11.8.14 Orthogonality and horizontal and vertical parallelism errors.

between the two axes, respectively. An example of horizontal parallelism error (taper) would be an axis on a lathe that was not parallel to the spindle's axis of rotation. Using this axis to move a tool along the outer surface of a part would result in the part becoming tapered along its length. An example of vertical parallelism error is two axes used to support a milling machine bed. If one end of one of the axes is high, the bed itself will be warped when bolted to the axes, and parts machined while bolted to the bed will wobble.

Kinematic errors in a well-designed and manufactured machine would be very repeatable and can be compensated for if the controller is well designed. However, the fundamental principle of modern precision machine design is still to *maximize mechanical performance for a reasonable cost before using special controllers, algorithms, and sensors to correct for mechanical errors.*

**External Load-Induced Errors.** External loads that cause errors in a machine include gravity loads, cutting loads, and axis acceleration loads. The difficulty in modeling load-induced errors lies in their often distributed and/or varying effects. The types of errors discussed thus far have been geometrically induced and were a function of position. Thus, they could be relatively easily included in the HTM model of a machine. Load-induced errors, on the other hand, are often distributed throughout the structure. In order to incorporate them into the HTM model, a method for lumping them at discrete points must be devised. Depending on the structure, the bearing interface is often the most compliant part of the structure, and it can make sense to lump load-induced errors at the bearing interfaces. For more complex structures, it may be necessary to introduce additional coordinate frames into the HTM model.

In addition to increasing accuracy for enhancement of quality, machines are being required to move at greater speeds in order to increase productivity. Machine tools are usually thought of as big, bulky, slow-moving structures. The next generation of machine tools, however, will probably require axes to have acceleration capabilities in excess of 1 g. Deflections caused by accelerating the mass are acceptable for many drilling operations which would allow high spindle speeds and high axis feed rates to be used to increase productivity. Acceleration and deceleration rates of high-speed manufacturing equipment's

axes may one day routinely approach several g. In designing this type of equipment, accuracy along the path of motion may or may not be critical. However, final placement and settling time, where the maximum accelerations and inertial forces are present, will be important. Note that in the design of this type of machinery, cutting forces are often insignificant compared to inertial forces.

Another major contributor to load-induced errors in machine tools and some robots are cutting forces. Fortunately, high-speed cutting processes often generate low cutting forces, so the problems of high acceleration and high cutting force usually do not occur simultaneously. However, cutting forces are applied at the tool tip and act on every element in the machine. In order to estimate forces generated by the cutting process, actual cutting forces on machines with similar tools should be measured or appropriate handbooks consulted. In many cases, the rapid advance of new types of cutting tool materials and tool shapes will require the design engineer to consult with a tooling manufacturer or make experimental tests.

*Load-Induced Errors from Machine Assembly.* Even if all machine components are within required tolerance prior to assembly, additional load-induced errors can be introduced during assembly. The first type of error is forced geometric congruence between moving parts. An example is the bolting of a leadscrew to a carriage, where the nonstraightness of the leadscrew shaft creates a straightness error in the carriage with a period equal to the lead of the screw. A common example is mounting a mirror at its four corners, which often creates a visible distortion. The second type of error is the effect of the assembly process on the stiffness of the structure itself, and how the stiffness can be evaluated and incorporated into the HTM model. A third type of error, one that can be predicted, is the deformation of the machine when forces are applied to preload bearings and bolts. In addition, errors may also be caused by clamping or locking mechanisms.

*Thermal Expansion Errors\**. The need for ever-increasing accuracy and greater machine speeds makes thermal errors ever more important to control. Errors caused by thermal expansion are among the largest, most overlooked, and misunderstood form of error in the world of machine design. Thermal errors affect the machine, the part, and the tool. Even the warmth of a machinist's body can disrupt the accuracy of an ultraprecision machine. [Figure 11.8.15](#) shows the thermal effects that must be accounted for in the design of a precision machine.\*\* Thermal errors are particularly bothersome because they often cause angular errors that lead to Abbe errors.

Temperature changes induce thermal elastic strains  $\epsilon_T$ , that are proportional to the product of the coefficient of expansion  $\alpha$ , of the material and the temperature change,  $\Delta T$ , experienced by the material:

$$\epsilon_T = \alpha \Delta T$$

In addition, temperature gradients often cause angular errors, which lead to Abbe errors. If a machine, a tool, and a workpiece all expanded the same amount and could all be kept at the same temperature, then the system might expand uniformly with respect to the standard (always measured at 20°C) and everything would be within tolerance when brought back to standard temperature. However, different metals manufactured at different temperatures can experience serious dimensional metrology problems. Fortunately, standards have been developed (e.g., ANSI B89.6.2\*\*\*) that define in great detail the effects of temperature and humidity on dimensional measurement and how measurements of these effects should be made. Although thermal strains can be minimized by using materials that do not expand very much,

---

\*  $C^\circ$  denotes temperature difference, whereas  $^\circ C$  denotes an absolute temperature. This helps to avoid confusion, particularly when reference is made to temperature increases above ambient.

and by accurately controlling the environment; in practice, however, these can be difficult solutions to implement for economic reasons.

### Structures

The detailed design of the machine structure requires an understanding of the errors in a machine and how they interact with the envisioned assemblage of components. When designing the structure, the engineer must have an overall philosophy in mind with respect to how to assemble the system and address principle types of errors.

For a precision machine, the engineer must first develop a strategy for attaining accuracy (these issues were addressed in the context of 11.8.1 “Analysis of Errors in a Precision Machine”):

- Accuracy obtained from component and assembly accuracy
  - Inexpensive once the process is perfected.
  - Accuracy is strongly coupled to thermal and mechanical loads on the machine.
- Accuracy obtained by error mapping a repeatable system
  - Inexpensive once the process is perfected.
  - Accuracy is moderately coupled to thermal and mechanical loads on the machine.
- Accuracy obtained from a metrology frame (measure the position of an inaccurate machine with respect to an accurate reference frame)
  - Expensive, but sometimes the only choice.
  - Accuracy is uncoupled to thermal and mechanical loads on the machine.

Next, a direction should be set regarding dynamic performance and how much is needed, by considering the following:

- System bandwidth requirements
- Effects of changing system parameters
- Methods to add damping
- Experimental modal analysis

Thermal errors are among the most difficult to predict and control, and an approach to address them should be established early on:

- Passive temperature control
- Active temperature control

With design approaches to the above, the next step is to consider structural materials and different machine configurations that are available:

- Materials
- Existing configurations

Finally, a decision should be made regarding the overall approach to be used with regard to how all the components are assembled:

- Elastically averaged design
- Kinematic design
- Bolted joint design
- Kinematic coupling design

These issues are discussed in greater detail below. Proper consideration of all the details takes a great deal of study\* and practice, but these highlights should be useful as an introduction, or as a refresher.

### Dynamic System Requirements

Engineers commonly ask “how stiff should the structure be?” A minimum specified static stiffness is a useful but not sufficient specification. For example, the machine can be made to not deflect too much under its own weight or the weight of a part. Fortunately, it can be predicted with reasonable accuracy. To obtain good surface finish or dynamic performance, the dynamic stiffness needs to be specified.

The dynamic stiffness of a system is the stiffness measured using an excitation force with a frequency equal to the damped natural frequency of the structure. The dynamic stiffness of a system is also equal to the static stiffness divided by the amplification at dynamic resonance. It takes a large amount of damping to reduce the amplification factor to a low level. There are several damping quantifiers that are used to describe energy dissipation in a structure. The quantifiers include:

$\eta$	Loss factor of material
$\eta_s$	Loss factor of material (geometry and load dependent)
$Q = A_r$	Resonance amplification factor
$\phi$	Phase angle $\phi$ between stress and strain (hysteresis factor)
$\delta_{Ld}$	Logarithmic decrement**
$\Delta U$	The energy dissipated during one cycle
$\zeta$	The damping factor associated with second-order systems

---

\* See, for example, Slocum, A. 1997. *Precision Machine Design*. Society of Manufacturing Engineers, Dearborn, MI. Much of the contents of this section was derived from this book.

\*\* Most texts on vibration refer to the log decrement as  $\delta$ , however, to avoid confusion with discussions on displacement termed  $\delta$ , the log decrement will be referred to here as  $\delta_{Ld}$ .

The various damping terms are related (approximately) in the following manner:

$$\eta = \frac{1}{A_r} = \frac{\delta}{\pi} = \phi = \frac{\Delta U}{2\pi U} \quad (11.8.18)$$

The logarithmic decrement  $\delta_{Ld}$  is an extremely useful measure of the relative amplitude between  $N$  successive oscillations of a freely vibrating system (one excited by an impulse):

$$\delta_{Ld} = \frac{-1}{N} \log_e \left( \frac{a_N}{a_1} \right) \quad (11.8.19)$$

The logarithmic decrement can also be related to the damping factor  $\zeta$ , velocity damping factor  $b$ , mass  $m$ , and natural frequency  $\omega_n$  of a second-order system model:

$$\zeta = \frac{\delta_{Ld}}{\sqrt{4\pi^2 + \delta_{Ld}^2}} \quad (11.8.20)$$

Note that the amplification at resonance of a second-order system is given by

$$Q = A_r = \frac{1}{2\zeta\sqrt{1-\zeta^2}} \quad (\zeta \leq 0.707) \quad (11.8.21)$$

For example, [Figure 11.8.16](#) shows the time decay of a fairly well-damped system. For this system,  $n = 4$ ,  $a_5 = 0.5$ ,  $a_1 = 1.5$ ,  $\delta_{Ld} = 0.275$ ,  $\zeta = 0.44$ , and  $Q = 11.5$ .

**FIGURE 11.8.16** Time decay signal from a fairly well-damped system struck with an impulse.

Machines with good dynamic performance achieve damping by material selection and by the bolted joints and bearing interfaces in the structure. Unfortunately, material and joint damping factors are difficult to predict and are often too low. Thus the designer must consider the stiffness, mass, and damping of the system, and be prepared to alter them to achieve the desired level of performance. For high speed or high accuracy machines, damping mechanisms may have to be designed into the structure in order to meet realistic damping levels. The first step, however, is to try and determine the bandwidth required with an initial estimate of the stiffness, mass, and damping in the system. Then with these goals, one can try to change the parameter that has the greatest impact on performance.

*System Bandwidth Requirements.* An estimate of the system’s servo bandwidth can be made by considering the motions the system is required to make. Most systems null high frequency disturbance forces with their own mass or added damping; however, lower frequency forces must be offset by forces from the controller/actuator. As a result, the servo bandwidth required is primarily a function of the types of moves that the system will be required to make. For start and stop moves (e.g., in a wafer stepper), the bandwidth should be on the order of

$$\omega(\text{hz}) = \frac{10}{2\pi t_{\text{settling time}}} \tag{11.8.22}$$

When contouring, the X and Y axis moves according to  $x = R\sin\omega t$  and  $y = R\cos\omega t$ , the frequency  $\omega$  is a function of the linear velocity of the cutter through the material, and the radius of the contour:

$$\omega(\text{hz}) = \frac{v_{\text{linear}}}{2\pi r_{\text{path radius}}} \tag{11.8.23}$$

For example, for a large circle (e.g., 200 mm D) being cut at modest speeds (e.g., 0.1 m/sec), the bandwidth required is only 0.16 Hz. On the other hand, for a sharp turn in a corner, the radius of the cutter path trajectory may only be 1 mm, so  $\omega > 16$  Hz. The latter is a reasonable requirement for a large machine tool, where the spindle axis may weigh 1000 kg and thus require a critically damped system stiffness of 10 N/μm, which means a design stiffness on the order of 100 N/μm when one considers the limited damping that is obtainable.

In order to make a better assessment of what system parameters should be, a simple model can be used in the early stages of design. For example, a system with a motor driving a carriage can be modeled as shown in [Figure 11.8.17](#).

**FIGURE 11.8.17** Effect of changing system mass on dynamic performance.

In this model:

- $m_1$  is the mass of a linear motor forcer or  $m_1$  is the reflected inertia of the motor rotor and leadscrew (or just a linear motor’s moving part):

$$M_{\text{reflected}} = \frac{4\pi^2 J}{l^2}$$

- $m_2$  is the mass of the carriage.
- $c_1$  is the damping in the linear and rotary bearings.
- $c_2$  is the damping in the actuator-carriage coupling and the carriage structure.
- $k_2$  is the stiffness of the actuator and actuator-carriage-tool structural loop.

The equations of motion of this system are

$$\begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix} \begin{bmatrix} \ddot{x}_1 \\ \ddot{x}_2 \end{bmatrix} + \begin{bmatrix} c_1 + c_2 & -c_2 \\ -c_2 & c_2 \end{bmatrix} \begin{bmatrix} \dot{x}_1 \\ \dot{x}_2 \end{bmatrix} + \begin{bmatrix} k_2 & -k_2 \\ -k_2 & k_2 \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = \begin{bmatrix} F(t) \\ 0 \end{bmatrix} \tag{11.8.24}$$

The transfer function  $x_2/F$  (dynamic response of the carriage) is

$$\frac{x_2}{F} = \frac{k_2 + c_2s}{c_1s(k_2 + c_2s + m_2s^2) + (m_1 + m_2)s^2(k_2 + c_2s) + m_1m_2s^4} \quad (11.8.25)$$

Note that the product of the masses term tends to dominate the system. To illustrate the design implications, consider four different calculated design options for a linear motion system shown in [Figure 11.8.18](#).

Actuator	ballscrew	lin. motor	lin. motor	lin. motor
Bearings	linear ball	linear ball	air	air
Structural damping	no	no	no	yes
material damping zeta	0.005	0.005	0.005	0.1
actuator to ground zeta	0.05	0.03	0	0
m1 (actuator) (kg)	50	5	5	5
m2 (carriage), kg	50	50	50	50
c1 (N/m/s)	187	355	0	0
c2 (N/m/s)	19	19	19	374
k1 (N/m)	1.75E+08	1.75E+08	1.75E+08	1.75E+08
Bandwidth (Hz)	25	100	30	100

**FIGURE 11.8.18** Calculated parameters of four possible linear motion systems.

As a guideline, the servo bandwidth of the system is generally limited by the frequency at which the servo can drive the system without exciting structural modes. Without special control techniques, the servo bandwidth can be no higher than the frequency found by drawing a horizontal line 3 dB above the resonant peak to intersect the response curve. This method is used only to initially size components. A detailed controls simulation must be done to verify performance and guide further system optimization. As an example, consider the response of the ballscrew-driven carriage supported by rolling element linear bearings, as shown in [Figure 11.8.19](#). In this case, since preloaded linear guides and a ballnut are used, damping to ground will be high. The inertia of the ballscrew will lower the system frequency considerably (note the  $m_1m_2s^4$  term in the transfer function). Going up 3 dB from the resonance peak and projecting to the left to intersect the response curve gives an estimate of the maximum bandwidth the machine can be driven at, without danger of exciting a resonance, of about 25 Hz.

*Effects of Changing the System's Mass.* Decreasing the mass of the system will enhance the ability of the machine to respond to command signals. However, the trade-off is that the system will lose the ability to attenuate high frequency noise and vibration as shown in [Figure 11.8.20](#).

A system with decreased mass offers a higher natural frequency, which means that higher speed controller signals can be used without compromising the accuracy of the system. A low mass system also shows improved damping, a result of the increased loss factor [the loss factor  $\zeta = c/(2m)$ ], but a low mass system shows less noise rejection at higher frequencies. This suggests that the machine will be less able to attenuate noise and vibration. Considering all the issues, in conclusion, the mass should be minimized to reduce controller effort and improve the frequency response and loss factor ( $\zeta$ ).

*Effects of Changing the System's Stiffness.* A system with higher stiffness will give a flatter response at low frequencies and give smaller displacements for a given force input. More importantly, the compromise of decreased noise attenuation is not as dramatic as is the case with lowering the system mass. This is shown by the similar shapes in the three curves at high frequencies in [Figure 11.8.21](#). However, acoustical noise may be worsened by adding stiffness. In conclusion, the stiffness of the machine structure should be maximized to improve positioning accuracy.

FIGURE 11.8.19 Frequency response of a ballscrew-driven system.

FIGURE 11.8.20 Effect of changing system mass on dynamic performance.

*Effects of Changing the System’s Damping.* Increasing the system’s damping can make a dramatic improvement in the system’s response. The trend is for decreasing amplification of the output at resonance with increasing damping, although a damping coefficient of 0.4 may be difficult to obtain in practice. Figure 11.8.22 shows the dramatic improvement available by doubling the system’s damping.

**Methods of Achieving Damping**

Although it has been extensively studied, the mechanism of damping in a material is difficult to quantify and one must generally rely on empirical results.\* In fact, damping is highly dependent on alloy

\* A discussion of the many different microstructural mechanisms that generate damping in materials is beyond the scope of this book. For a detailed discussion see Lazan, B.J., *Damping of Materials and Members in Structural Mechanics*. Pergamon Press, London.

FIGURE 11.8.21 Effect of changing system stiffness on dynamic performance.

FIGURE 11.8.22 Effect of changing system damping on dynamic performance.

composition, frequency, stress level and type, and temperature. Structural damping levels are often quite low, and frequently the dominant source of damping is the joints in an assembly. In fact, one must be extremely wary of damping data that are presented in the literature, because often it is presented without a discussion of the design of the test setup.

The amount of damping one obtains from a material is very low compared to the amount of damping that one can obtain with the addition of a damping mechanism. Damping mechanisms can range from simple sand piles to more complex shear dampers or tuned mass dampers as discussed below. In general, cast iron is the best damped structural metal. Polymer concrete or granite make well-damped structures that tend to be more monolithic in nature; but ceramics have very poor damping.

**Tuned Mass Dampers.** In a machine with a rotating component (e.g., a grinding wheel), there is often enough energy at multiples of the rotational frequency (harmonics) to cause resonant vibrations in some of the machine's components. This often occurs in cantilevered components such as boring bars and some grinding wheel dressers. The amplification at a particular frequency can be minimized with the use of a tuned mass damper. A tuned mass damper is simply a mass, spring, and damper attached to a structure at the point where vibration motion is to be decreased. The size of the mass, spring, and damper

are chosen so they oscillate out of phase with the structure and thus help to reduce the structure's vibration amplitude.

Consider the single-degree-of-freedom system shown in Figure 11.8.23. The system contains a spring, mass, and damper. For a cantilevered steel beam, the spring would represent the beam stiffness, the mass would be that which combined with the spring yielded the natural frequency of the cantilevered beam, and the damper would be that which caused a 2% energy loss per cycle. As also shown in Figure 11.8.23, a second spring-mass-damper system can be added to the first to decrease the cantilevered beam's amplitude at resonance. The equations of motion of the system are

FIGURE 11.8.23 Cantilever beam, model, and model with tuned mass damper.

$$\begin{bmatrix} m_1 & 0 \\ 0 & m_2 \end{bmatrix} \ddot{x}(t) + \begin{bmatrix} c_1 + c_2 & -c_2 \\ -c_2 & c_2 \end{bmatrix} \dot{x}(t) + \begin{bmatrix} k_1 + k_2 & -k_2 \\ -k_2 & k_2 \end{bmatrix} x(t) \tag{11.8.26}$$

In the frequency domain, in order to present a solution for the motion of the system, the following notation is introduced:

$$Z_{ij}(\omega) = -\omega^2 m_{ij} + i\omega c_{ij} + k_{ij} \quad i, j = 1, 2 \tag{11.8.27}$$

The amplitudes of the motions of the component and the damper as a function of frequency are given by\*

$$X_2(\omega) = \frac{-Z_{12}(\omega)F_1}{Z_{11}(\omega)Z_{22}(\omega) - Z_{12}^2(\omega)} \tag{11.8.28}$$

The design of a tuned mass damper system for a machine component may involve the following steps:

- Determine the space available for the damper and calculate the mass ( $m_2$ ) that can fit into this space.
- Determine the spring size ( $k_2$ ) that makes the natural frequency of the damper equal to the natural frequency of the component.
- Use a spreadsheet to generate plots of component amplitude as a function of frequency and damper damping magnitude ( $c_2$ ).

*Constrained Layer Dampers.* The structural joints in a machine tool have long been known to be a source of damping by the mechanisms of friction and microslip. A study of structural joint damping has shown that numerous theories are available for predicting damping by these mechanisms,\*\* however, the amount of damping obtained is still less than what is required for critical damping, and controlling the surface interface parameters at the joint to achieve uniform results from machine to machine is difficult. In addition, as far as the accuracy of the machine is required, it would be best if the joints behaved as

\* Ibid., p 115.

\*\* See, for example, Tsutsumi, M. and Ito, Y. September 1979. Damping mechanisms of a bolted joint in machine tools, *Proc. 20th Int. Mach. Tool Des. Res. Conf.*, pp. 443–448; and Murty, A.S.R. and Padmanabhan, K.K. 1982. Effect of surface topography on damping in machine joints. *Precis. Eng.* 4(4):185–190.

**FIGURE 11.8.24** Increasing structural damping by adding alternate layers of viscous and structural materials.

a rigid interface which, as discussed below, can be obtained by bolting and grouting (or bonding) a joint. A better method is to add damping by applying alternate layers of viscoelastic and structural materials to a machine tool structure,\* as illustrated in [Figure 11.8.24](#).

### Experimental Modal Analysis of a Machine's Dynamic Performance

The manner in which a machine behaves dynamically has a direct effect on the quality of the process. It is vital to be able to measure a machine's dynamic performance to enable engineers to determine exactly which parts of a machine need to be strengthened or made to be better damped.

Experimental modal analysis allows the study of vibration modes in a machine tool structure. An understanding of data acquisition, signal processing, and vibration theory is necessary to obtain meaningful results. For a modest-sized company (50 employees), it is feasible and reasonable to have one person dedicated to metrology, including experimental modal analysis. Companies routinely invest \$100,000 or more in precision measurement devices (e.g., gauges, autocollimator, laser interferometer, ball bar, surface roughness, etc.). The dynamic performance of a machine is every bit as important, and requires only a modest investment (about \$40K).

When a company's metrologist is trained in modal analysis, results can be rapidly obtained and presented to the design department. For example, suppose a new machine is being designed where axial stiffness of the drive system is of extreme importance (e.g., a centerless grinder). The design engineer wants to know if a rollerscrew will give better performance than a ballscrew. Not completely trusting catalog data, and not knowing the primary source of compliance (the mounting, the bearings, the shaft, or the nut), the engineer replaces a ballscrew — in a known good machine — with a rollerscrew. The metrologist does the modal analysis and the engineer learns in “real time” what the result is. Similarly, the engineer can look to other machines on the shop floor for physical models of elements to be used in a new design, and the metrologist can make the measurements in a short time.

All too often a modal analysis is done after a design is complete to help solve a problem. The results can often be used to help repair the problem; however, done before hand, modal testing of similar machines or test-subassemblies would have led to a better design approach that in the end would have resulted in a better integrated system. The results of a modal analysis yield important information regarding the machine's dynamic properties, including:

- Modal natural frequencies
- Modal damping factors
- Vibration mode shapes

\* See, for example, Haranath, S., Ganesan, N., and Rao, B. 1987. Dynamic analysis of machine tool structures with applied damping treatment. *Int. J. Mach. Tools Manuf.* 27(1):43–55. Also see Marsh, E.R., Slocum, A.H. 1996. An integrated approach to structural damping. *Precis. Eng.*, 18(2,3):103–109.

This information is vital to a designer, who may use the information to

- Locate sources of compliance in a structure.
- Characterize machine performance.
- Optimize design parameters.
- Identify the weak links in a structure for design optimization.
- Identify modes which are being excited by the process (e.g., an end mill) so that structure can be modified accordingly.
- Identify modes (parts of the structure) which limit the speed of operation (e.g., in a coordinate measuring machine).

A manager may ask “why should we start doing this if we have not done it in the past, and were very successful?” The engineering answer is that faster and more accurate machines are needed in the future, and the materials being processed are getting harder and harder (e.g., ceramics). The business answer is that the problems are getting tougher to solve, and engineering time is expensive. Also, international competition is more widespread and much tougher. History has shown that application of new advanced tools virtually always guarantees an increase in performance and competitive edge.

### **Identification, Control, and Isolation of Heat Sources\***

Heat that causes thermal errors is introduced into the machine from a number of sources including moving parts (e.g., high-speed spindles, leadscrew nuts, linear bearings, transmissions), motors, the material removal process, and the external environment (e.g., sunshine through a window, direct incandescent lighting, heating ducts, the floor, operators’ body heat, etc.). Heat transfer mechanisms in a machine include conduction, convection, evaporation,\*\* and radiation. They are executed by recirculating lubricating oil and cutting fluid, chips from the cutting process, conduction through the frame of the machine, convection of air in and around the machine, and internal and external sources of radiation.

There are three schools of thought regarding minimization of thermally induced errors. The first is to prevent thermal expansion in the first place. The second is to minimize the time it takes for the machine to reach its equilibrium temperature, or in some cases, bring the entire machine to a uniform temperature (e.g., circulate, temperature-controlled fluid through the machine), which can help to minimize differential expansion. The third is to disregard the effects of thermal errors and simply map them, which is a very difficult and often impractical thing to do. Regardless of the methodology followed, a thorough understanding of the effects of heat sources and transfer mechanisms is required, which is beyond the scope of this work.

The manner in which the temperature of a machine is to be controlled can have a large impact on the machine’s design. In summary, there are many options available to the design engineer:

- Passive temperature control:
  - Minimize and isolate heat sources.
  - Minimize coefficient of thermal expansion.
  - Maximize thermal conductivity to minimize thermal gradients.
  - Maximize thermal diffusivity to quickly equilibrate transient thermal effects.
  - Minimize thermal emissivity of the structure to minimize radiant coupling to the environment, or maximize the emissivity to couple the structure to an environmental control enclosure.

---

\* An important reference to have that discusses many of the issues discussed here in greater detail is *Temperature and Humidity Environment for Dimensional Measurement*, ANSI Standard B89.6.2-1973.

\*\* Evaporation cooling occurs when aqueous fluids are used. Evaporative cooling is usually uneven and represents one of the biggest temperature control problems facing the precision machine design engineer.

- Active temperature control:
  - Air showers
  - Circulating temperature-controlled fluid within the machine
  - Oil showers
  - Thermoelectric coolers for localized temperature control of hot spots

Each conceptual design option must consider how the temperature within the machine will vary if each of these different temperature control strategies were applied.

## Material Considerations

For the conceptual design phase, one should design the structure using differently available materials, and then also design a multimaterial hybrid. For example, cast iron can be made into virtually any shape, so the design engineer has greater freedom, but large sections are expensive to thermally anneal, which must be done to achieve material homogeneity and stability. Granite is usually used in the form of simple rectangular, circular, or planar shapes. Ships are made from welded steel plate and thus conceivably any size of machine tool could also be welded together. Polymer concrete can be cast into virtually any shape and requires no stress relief or prolonged aging cycle. With new ceramics and composite materials, the choices become even more varied, so one really must be alert and consider all options.

### Cast Iron Structures

The good general properties of cast iron and the ease with which parts can be cast have made cast iron the foundation of the machine tool industry. Generally, when a machine tool component is smaller than a compact car, it is a candidate for being made of cast iron, although castings weighing hundreds of tons have been made. For larger parts or where economy is of prime importance, one should consider welding together plates and standard structural shapes (e.g., boxes, angles, I-beams, and channels), as discussed below.

Sand casting can be used to make virtually any size part, and it basically involves making a pattern out of a suitable material (e.g., foam, wood, or metal) and packing sand around it. Parting lines are used to allow the sand mold components to be disassembled from around the pattern and then reassembled after the part is removed. Sand cores are often inserted into the mold to form cavities inside the mold (e.g., the cylinders of an engine casting). Regardless of the design of the part, one must also consider that as the metal cools it shrinks (on the order of 5 to 10% for most metals), and that in order to remove the part from the mold without breaking the mold, a taper (draft) of about 1:10 is required. In addition, extra metal should be added to surfaces that will have to be machined (a machining allowance), and locating surfaces should be added so that the part can be fixtured to facilitate machining. Thus in order to specify a casting, there are a few basic guidelines one needs to know in order to minimize the work that a professional mold design engineer has to do to clean up your design. These guidelines are discussed below.\*

### Granite Structures\*\*

Granite is used as a structural material in machines that are generally used in dry environments because granite can absorb moisture and swell. Thus it may not be appropriate to use granite in a machine where cutting fluid splashes all over it, although there is some debate as to how susceptible to swelling granite actually is. Granite can be sawed into a part of virtually any shape or size (deviations from round slabs

---

\* See, for example, the handbook *Casting Design as Influenced by Foundry Practice*. Mechanite Metal Corp., Marietta, GA.

\*\* A good source of design information about what shapes and sizes can be made is available from Rock of Ages Corp., Industrial Products Group, P.O. Box 482, Barre, VT 05641.

or rectilinear shapes can be expensive). Since it is a brittle material, sharp corners are not allowed, and most structures are built from pieces that are bolted (using inserts) and grouted or bonded together. Since granite is brittle, threaded holes cannot be formed, and thus threaded inserts must be glued or press-fit into round holes in the granite. Common applications of granite components in machine tools include structural members and air-bearing ways in coordinate measuring machines and other inspection machines. Note that the porosity of some granite makes it unsuitable for air bearings even after it has been polished.

The low thermal conductivity of granite makes it slow to absorb heat. This makes granite, particularly black granite, susceptible to thermal distortions caused by the top surface absorbing heat from overhead lights. Granite's coefficient of thermal expansion is less than that of most metals, so in the process of manufacture, shipping, and use, one must consider how differential thermal expansion will affect a machine's performance if metal components have been bolted to it. Although granite has been sitting in the ground for millions of years and thus may seem to possess the ultimate stability, one must consider the effects of relieving the stress upon the granite's dimensional stability after it has been quarried. There are suppliers of very stable granite components, so the design engineer must carefully shop around. A very desirable property of granite (or any other brittle material) is that it will chip when banged instead of forming a crater with a raised lip (Brinell). Granite is also relatively inexpensive to quarry, cut, and lap. Hence granite is often the material of choice for coordinate measuring machine tables.

### **Welded Structures\***

Welded structures can be made from any weldable alloy (e.g., iron alloys such as 1018 structural steel or Invar). Welded structures (weldments) are commonly used, for example, where (1) the cost of a large structure is to be minimized, (2) a high degree of material damping is not needed or the structure will be filled with a damping material, and/or (3) the part is too large to be cast and thermally stress relieved economically. If welded properly, so that the weld material is in a metallurgically stable form, residual stresses can sometimes be removed using vibratory stress-relief methods.

A welded structure is similar to a cast structure, in that strength and stiffness are achieved through the use of sections that are reinforced with ribs; consequently, structural analysis can be difficult and beyond the conceptual design phase often requires the use of finite element methods. Damping and heat transfer characteristics across welded joints are also difficult to model because they are dependent on depth of weld penetration, composition of the weld material, and contact pressure between member surfaces at the joints where the weld does not penetrate. One solution is to specify full penetration welds. To minimize the cost of welded structures, the number of parts and linear meters of weld must be minimized. Furthermore, the more welds that are made, the greater the thermal distortion that is likely to occur as a result of the manufacturing process. However, if too few ribs are used, large plate sections can vibrate like drums. Damping and thermal performance of a welded structure can improve greatly if a viscous temperature-cooled fluid is recirculated throughout the structure, or if damping mechanisms are used as described above. A welded structure can also be used as a mold for a polymer concrete casting which creates a heavy but well-damped and stiff structure, but care must be taken to avoid bimaterial thermal deformation problems.

### **Ceramic Structures\*\***

The first introduction of a machine that was made almost entirely of ceramics was in 1984 at the Tokyo machine tool show. Although all-ceramic machines generally perform admirably, they have yet to compete economically with machines made from cast iron or polymer concrete. However, in the future,

---

\*\* See, for example, Ormiston, T. September 1990. Advanced Ceramics and Machine Design. *SME Tech. Paper* EM90-353.

as more and more ceramic components are made for use in consumer products (e.g., automobiles), it is likely that precision machines will contain more and more ceramic components.\*

Hard materials (e.g., ceramics) offer advantages over conventional materials in terms of dimensional stability, strength, and stiffness over a wide range of temperatures. In applications ranging from adiabatic internal combustion engines for maximum efficiency to X-ray mirrors for X-ray photolithography, the ability to manufacture components from hard materials is clearly of vital importance to the future of the manufacturing industry. Unfortunately, most ceramic components are finish machined on machines built from cast iron and the abrasive nature of ceramics limits the life of these machines. Thus a new family of machine tools and machine tool components will have to be developed specifically for the manufacture of ceramic components. Consider several key properties of some ceramic materials that can help guide the design process for new machines:

- Most ceramic materials (e.g., aluminum oxide and silicon nitride) will not corrode in any fluid environment that might be used in the manufacture of ceramic components (i.e., fluids from oil to water).\*\* Thus ceramics are key materials for water hydrostatic bearings.
- The more brittle a material is, the less plastic deformation that is generated during finish grinding or lapping; hence the surface is more likely to have a negative skewness. A surface with a negative skewness minimizes the need for a lubricant that has good wetting properties that allows for water to be considered as a lubricant. A surface with a negative skewness will also suffer less damage in the event that the lubricant is lost.
- The more brittle a material is, the less plastic deformation that is generated during finish grinding; hence the surface is less likely to contain high residual stress levels that can lead to dimensional instability. In addition, a precision machine should not be subjected to shock loads in the first place. For general machine tool applications, such as bearing rails, the element geometry generally provides more than enough strength to withstand impact loads generated when a machine crashes.
- Generous radii must be used in all corners, and threaded steel inserts must be used if parts are to be bolted to ceramic components. To bond two ceramic components together, conventional adhesives can be used, or for high-performance applications, ceramic parts can be frit bonded. In frit bonding, a glass powder is applied to the two mating surfaces and then fused by heating the parts above the melting point of the glass. The bond will not be as strong as the ceramic, but it will be almost as stiff.
- Unlike some metals, elements do not precipitate out of a ceramic material's microstructure with time (e.g., carbides do not form like in some iron alloys) so dimensional stability is enhanced. Thus ceramic components can also have virtually unmatched dimensional stability. For metrology masters (e.g., squares and straight edges), ceramics are much lighter than conventional materials, they are less likely to be damaged (dropped) in the first place, and they are less likely to become scratched or worn in everyday use.
- Most ceramics are pure and thus the achievable surface finish is limited only by the size of the grain structure formed during the sintering process; however, most advanced ceramic materials have submicron sizes and this effect is usually not a problem the way it can be with metals. Also note that metals contain discrete hard particles that are dragged across the softer surface during machining which degrades surface finish.

---

\* Furukawa, Y. et al. 1986. Development of ultra precision machine tool made of ceramics. *Ann. CIRP*. 35(1): 279–282.

\*\* Aluminum oxide components are subject to stress corrosion cracking in aqueous environments and thus care must be taken to minimize tensile stresses. Note that silicon-based ceramics, which have predominantly covalent molecules, are far less reactive with water. Only at high temperature and pressure do silicon-based ceramics become appreciably affected by aqueous environments.

- Ceramic materials have a high modulus that is good for machine stiffness, but some have poor thermal properties (e.g., alumina) that can lead to increased thermal deformations of the machine. Note that silicon carbide has very good thermal properties but it is considerably more expensive than alumina
- Ceramic materials in intimate contact will not gall or fret the way many metals often do; thus they make excellent bearing surfaces. However, when ceramic materials are in intimate sliding contact, traction forces can cause the local tensile strength to be exceeded, which produces surface cracks that lead to spalling. In such situations, it may be desirable to use a ceramic material with a high fracture toughness and tensile strength (e.g., silicon nitride). Thermal stresses can also initiate local or gross failure.
- Ceramic materials have a higher modulus of elasticity and lower density than do bearing steels; hence ceramic rolling elements have a smaller contact zone that leads to less heat generation. Hybrid bearings (e.g., metal rings and ceramic rolling elements) generate 30 to 50% less heat than do steel bearings. This means that grease can be used to lubricate the bearings at much higher speeds.\* In general, for smaller diameter ultraprecision bearings, hybrid bearings can have up to three times the DN value of steel bearings (i.e., 4.5 million vs. 1.5 million).
- Aluminum oxide has good overall properties for structural applications such as fluidstatic bearing rails and CMM structures. Zirconia is very tough, and its coefficient of thermal expansion matches that of steel, so it can be used as a bearing rail liner for rolling element bearings without worrying about bimaterial expansion problems. However, most zirconias are multiphase materials and thus are not well suited for applications where high-dimensional stability is required (e.g., in precision bearings). Silicon nitride has the best overall properties including very high toughness, which makes it ideal for rolling element bearings, but it is too expensive to use for large structural components. Silicon carbide and tungsten carbide are extremely hard and wear-resistant and they are often used in cutting tool applications.
- Aluminum oxide components can be made by cold pressing followed by machining, firing, and grinding. Note that there is significant volume shrinkage during the firing process. Hence designing ceramic structural parts often requires assistance from the manufacturer. In general, the same shape design rules apply as for metal castings, and the wall thickness should not be greater than about 25 mm. Ceramics components (e.g., those made from silicon nitride) can also be made by hot pressing followed by grinding and lapping.

### Polymer Concrete Castings\*\*

Portland cement-based concrete is not dimensionally stable enough, due to its own internal structural variations with time and its hygroscopic nature, to allow it to be used for the main structure of a precision machine tool. Although in many applications, properly cured reinforced concrete on a stable, dry subgrade can provide a reasonably stable foundation for very large machines that are not self-supporting, unreinforced Portland cement concrete itself is not dimensionally stable due to (1) reaction shrinkage from cement hydration; (2) shrinkage due to loss of excess nonstoichiometric water, which leaves conduits for humidity-induced expansion or contraction; and (3) nonelastic dimensional changes (e.g., creep and microcracking in the inherent brittle/porous structure). Overall, strain variations with time may be as high as 1000  $\mu\text{m}/\text{m}$ .

---

\* Steel bearings require oil mist lubrication at higher speeds. Introducing an oil mist (oil dripped into a high-pressure air stream) into a bearing increases the chance that water and dirt particles might be introduced into the bearing, which can lead to premature failure. Actually, a precision bearing cooled by an oil mist should have its air cleaned and dried to a level usually associated with air bearings (e.g., 3- $\mu\text{m}$  filter and  $\text{H}_2\text{O} < 50$  to 100 ppm).

\*\* See, for example, Capuano, T. September 10, 1987. Polymer concrete. *Mach. Des.* 133–135; Jablonowski, J. August 1987. New ways to build machine structures. *Am. Mach. Automat. Manuf.* 88–94; and McKeown, P.A. and Morgan, G.H. 1979. Epoxy granite: a structural material for precision machines. *Precis. Eng.* 1(4): 227–229.

Fortunately, a number of different types of polymer-based concretes have been developed which can be used to cast machine tool quality structures. For example, Fritz Studer AG, a prominent manufacturer of precision grinders in Switzerland, discovered that special polymers can be used to bind together specially prepared and sized aggregate to yield a stable, essentially castable, granite-like material with a damping coefficient much higher than that of cast iron.\* By carefully controlling the manufacturing process and selection of binder and aggregate, properties can be varied somewhat to suit the user. The polymer concrete material and process developed by Studer is known as Granitan™ and its composition and manufacturing process was patented. Numerous companies have licensed the process and will make castings from Granitan™ to order. Other companies have developed their own proprietary polymer concretes with similar high performance properties.

For polymer concrete castings, the same rules for draft allowance apply as for metal castings if the mold is to be removed. Instead of ribs, polymer concrete structures usually use internal foam cores to maximize their stiffness-to-weight ratio. Unlike metal castings, a polymer concrete casting will not develop hot spots while curing even in thick, uneven sections. Polymer concrete castings can readily accommodate cast-in-place components such as bolt inserts, conduit, bearing rails, hydraulic lines, etc. It should be noted that a bolt will fail before a bonded-in-place insert.

With appropriate section design, polymer concrete structures can have the stiffness of cast iron structures and much greater damping than cast iron structures.\*\* However due to polymer concretes' lower strength, heavily loaded machine substructures (e.g., carriages) are still best made from cast iron. Polymer concretes do not diffuse heat as well as cast iron structures and thus attention must be paid to the isolation of heat sources to prevent the formation of hot spots in a polymer concrete structure. In addition, their modulus of elasticity is about one fifth that of steel, and their strength is an order of magnitude less, so they are used primarily for machine bases.

## Structural Configurations

For proper functioning of moving axes and operational stability, often it is important to minimize thermal and elastic structural loops. By this it is meant that the path length from the toolpoint to the workpiece through the structure should be minimal. The less material that separates the part of the structure that holds the tool and the part of the structure that holds the part, the more likely the entire system will quickly reach and maintain a stable equilibrium.

### Open-Section (C or G) Frames

Most small machines are designed with an open frame, as shown in [Figure 11.8.25](#) which greatly facilitates workzone access for fixturing and part handling. Note that the machine could be designed with the spindle oriented in the horizontal or the vertical direction. Unfortunately, open section frames are the least structurally and thermally stable. The lack of symmetry leads to undesirable thermal gradients and bending moments. The fact that a critical part of the structure is cantilevered means that Abbe errors abound; hence great care must be used when designing a precision machine with an open frame. Note that there are many different variations on this design for different types of machines (e.g., milling machines and lathes). The common feature of all is the fact that the structural loop is open.

### Closed-Section (Bridge or Portal) Frames

Most large machines are designed with a closed frame as shown in [Figure 11.8.26](#). When the Z motion is built into the bridge, a second actuator must often be slaved to the primary actuator that moves the

Eng.* 7(3): 165–170; and Salje, I. et al. 1988. Comparison of machine tool elements made of polymer concrete and cast iron. *Ann CIRP*. 37(1): 381–384.

**FIGURE 11.8.25** Structural loop in an open-frame machine tool.

**FIGURE 11.8.26** Structural loop in a closed-frame (bridge) machine tool.

bridge. This prevents the bridge from yawing (walking). Note that there are many different variations on this design for different types of machines (e.g., milling machines and lathes). The common feature of all is the fact that the structural loop is closed.

**Tetrahedral Frames**

Nature invented the tetrahedron and found it to be an immensely stable and powerful form (e.g., diamonds). In engineering and architecture, the tetrahedron represents the three-dimensional application of the age-old structure of stability, the triangle. Lindsey of NPL in England took these basic building blocks of nature and added well-engineered damping mechanisms to yield a major advancement in the

**FIGURE 11.8.27** Tetraform structural concept for machine tools and instruments developed by Lindsey. (Courtesy of the National Physical Laboratory.)

structure of machine tools. The *Tetraform* machine tool concept is shown in [Figure 11.8.27](#). The structures owes its exceptional dynamic performance to the following:<sup>\*</sup>

- Damping in the legs is achieved through the use of inner cylinders which dissipate energy through viscous shear. Energy is dissipated via squeeze film damping and relative sliding motion damping.
- Damping at the joints is achieved by a sliding bearing (PTFE) interface.
- Microslip at the joints does not affect the dimensional stability of the machine because the minimum energy form of the tetrahedron wants to be preserved. Unlike a plane joint which can continue to slip and lead to dimensional instability, the tetrahedron's legs' spherical ends want to stay on the spherical joint nodes.

The latter point has even more profound consequences, in that it makes the use of composite materials in the structure an attractive alternative to metals or ceramics. Wound carbon fiber tubes can be designed to have a zero coefficient of thermal expansion along their length and they can have stiffness-to-weight ratios two times higher than are obtainable with metals. It would be difficult to design a conventional machine tool that made economical use of the desirable properties of carbon fibers.

### Counterweights and Counterbalances

Counterweights, shown in [Figure 11.8.28](#) can be used to minimize gravity loads. This helps minimize the holding torque required of servomotors, which in turn minimizes motor size and heat input to the machine. For a very high precision machine, however, the bearings used to guide the counterweights and support the pulley bearings should have negligible static friction. Counterweights also increase the mass of the system, which can decrease dynamic performance. In the case of quasistatic axes (e.g., large gantry-type surface grinders), the counterweight can increase the load on the structure that supports the axes, and if the structure is cantilevered, then as the counterbalanced axis moves, the deflection errors

<sup>\*</sup> This concept is protected by worldwide patents. See, for example, U.K. patent 8,719,169, or contact the British Technology Group, 101 Newington Causeway, London, SE1 6BU, England.

**FIGURE 11.8.28** Use of a counterweight to balance the deadweight of an axis.

caused by the weight of the counterbalanced axis will change. Alternatively, a separate frame and low-accuracy slave carriage can be used to support the counterweights.

A counterbalance can be any passive means used to support the weight of an axis that moves in a vertical direction. Pistons have been used successfully but they can impart frictional and misalignment forces. A very effective counterbalance method is to use a float. This also provides viscous damping if the fluid used is a viscous oil.

### Compensating Curvatures

All structures have finite stiffness, and when loads are applied, lateral and angular displacements will result. To compensate for these effects, it is possible to shape the otherwise straight ways of an axis so that the sum of the deflections and the intentional nonstraightness results in minimal net straightness error. This type of correction is known as a *compensating curvature*. Usually, it is very difficult to also compensate for angular errors. If the error budget is properly assembled, it can be used to plot the total error as a function of the position of an axis. Once the plot is found, it can be used to help design a shape (ideally, the inverse of the plot) that will cancel the lateral and hopefully also angular errors for the given bearing design. Compensating curvatures can easily be measured using an autocollimator.

When the load does not greatly change on parts moving along axes that are curvature compensated (e.g., axes that carry a measuring head), the method can be effective. If the loads do change greatly (e.g., a table carrying different weight parts and fixtures), the compensating curvature can sometimes decrease performance. One of its main attractions, however, is that once the correct compensated curvature and manufacturing process is found for a particular machine, it can be the least expensive way to correct for straightness errors.

With modern mapping techniques, compensating curvatures are used primarily on very large structures or when angular errors caused by deflection are too large and cannot be corrected for by another axis. For example, they might be used in a situation where otherwise the toolpoint would enter the workpiece at an angle rather than being perpendicular. A rotary axis would be required to compensate for this type of angular error, as opposed to just another linear axis, which can only be used to compensate for an Abbe error.

### Structural Connectivity

*The principle of kinematic design* states that point contact should be established at the minimum number of points required to constrain a body in the desired position and orientation (i.e., six minus the number of desired degrees of freedom). This prevents overconstraint, and thus an “exact” mathematically continuous model of the system can be made. Kinematic locating mechanisms range from simple pins to Gothic arch-grooved three-ball couplings shown in [Figure 11.8.29](#). Kinematic designs, however, are

**FIGURE 11.8.29** Flat-groove-tetrahedron (Kelvin clamp) and three-vee-groove kinematic couplings. In both cases, the balls are mounted to an upper plate (not shown) which is held in position with respect to the lower plate by the coupling.

subject to high-contact stresses, which often may require the use of ceramic components (e.g., silicon nitride balls and grooves) if the highest level of performance is to be achieved. If stress and corrosion fatigue are controlled, repeatability of a kinematic system can be on the order of the surface finish of the points in contact if the loads are repeatable or the preload high enough. Finite contact areas do exist, and they effectively elastically average out the local errors due to surface roughness. In addition, note that friction and microindentation will limit the accuracy of the kinematic model.

Kinematic support of a structure is often desired to ensure that the structure is not deformed by inaccuracies or instabilities of the mounting surface. For a small instrument, only one of the kinematic mounting points may be rigidly connected and the other two may consist of flexures that will allow for differential thermal growth between the instrument and the mounting surface. Friction does exist in kinematic couplings, and thus forces can be transmitted between a mounting surface and an instrument.

The principle of *elastic averaging* states that to accurately locate two surfaces and support a large load, there should be a very large number of contact points spread out over a broad region. Examples include curvic or Hirth couplings, which use meshed gear teeth (of different forms, respectively) to form a coupling. The teeth are clamped together with a very large preload. This mechanism is commonly used for indexing tables and indexing tool turrets. Figure 11.8.30 shows an indexing and clamping mechanism for a lathe tool turret. Note that many different types of clamping preload systems exist. However, this type of mechanism causes the system to be overconstrained; on the other hand, if an elastically averaged system is properly designed, fabricated, and preloaded, the average contact stress will be low, high points will wear themselves in with use, and errors will be averaged out by elastic deformation. The system itself will then have very high load capacity and stiffness. For a worn-in elastically averaged system, the repeatability is on the order of the accuracy of the manufacturing process used to make the parts divided by the square root of the number of contact points (i.e., teeth in a tooth coupling). Still, because of the large number of contact points, the chance of dirt contaminating the interface increases.

With respect to the connectivity between structural elements (e.g., a headstock and a bed), elements of a structure can either be connected together via:

- Kinematic design
  - Deterministic
  - Less reliance on manufacturing
  - Stiffness and load capacity limited
- Elastically averaged design
  - Nondeterministic
  - More reliance on manufacturing
  - Stiffness and load capacity not limited

**FIGURE 11.8.30** Typical turret indexing and locking mechanism in engaged and disengaged positions.

It should be noted that overconstrained systems cannot accommodate differential thermal growth and hence are more prone to warping. Furthermore, finite deformation of the contact surface leads to micromechanical constraints that limit the true kinematicity of the structure. The use of hard materials (e.g., ceramics) helps to minimize the latter problem. For permanently connected components, one can align them using a kinematic location system and then inject epoxy or grout to create a bond between all the surfaces in close proximity, although with this method, one must make sure that the shrinkage of the bond material does not warp the components.

**Bolted Joints**

Bolts can be used to prevent two parts from separating or sliding relative to one another. For the former, the tensile forces across the joint are transferred through the bolt shaft. For the latter, sliding motion is resisted by frictional forces generated from the normal load on the joint produced by tightening of the bolt and the coefficient of friction between the joint’s parts. Because more than one bolt is usually used at a joint, it would be virtually impossible to ensure a tight fit of the bolt shafts in the holes, so it is not even worth trying. Sufficient lateral stiffness is usually provided by bolt preload and joint friction. For better resistance to shock loads, parts can be bolted in place and then holes drilled, reamed, and pinned with hardened steel dowels or roll pins. *In situ* drilling and reaming of the holes through both parts while they are bolted together maintains hole alignment, so multiple pins can be used.

Figure 11.8.31 illustrates the cross section of a typical portion of a bolted joint. A common bolt configuration used to bolt bearing rails for T-slides is shown in Figure 11.8.32. Many rails have a double row of bolts. In general, the cantilevered length should not exceed the bedded length. Ideally, the bedded length should be about 1.5 times the cantilevered length, but sadly this often takes up too much room. Furthermore, the stress cones under the boltheads should ideally overlap to maximize stiffness and minimize rail waviness. In practice, however, as shown in Figure 11.8.33 adequate stiffness can be obtained from a wider bolt spacing. The total stiffness for N segments of a bearing rail (e.g., N segments under a bearing pad) is given by\*\*

$$K_{\text{Rail}} = \frac{N_{\text{Segments}}}{\frac{1}{K_{\text{Rail bend \& shear}}} + \frac{1}{K_{\text{Joint}} + \frac{1}{\frac{1}{\frac{1}{K_{\text{Flange comp}}} + \frac{1}{K_{\text{Flange shear}}} + \frac{1}{K_{\text{Bed Shear}}} + \frac{1}{K_{\text{Bolt}}}}}}$$

\* For a more detailed discussion, see, for example, Bickford, J.H. 1981. *An Introduction to the Design and Behavior of Bolted Joints*. Marcel Dekker, New York; as well as A. Blake’s book.

\*\* The theory and practical implementation implications of bolted joints for machine tool applications are beyond the scope of this work. These are discussed in greater detail in Slocum, A. 1997. *Precision Machine Design*. Society of Manufacturing Engineers, Dearborn, MI.

FIGURE 11.8.31 Typical components of a bolted assembly.

FIGURE 11.8.32 Counterbored and bolted bearing rails with equal stiffness.

Bolt diameter is not a sensitive parameter for stiffness when bolt spacing is made a function of the bolt diameter. When the length of the bolt and the cone are expressed as bolt lengths, bolt joint stiffness becomes linearly dependent on the bolt diameter. As a result, bolt diameter cancels out as shown in Figure 11.8.33.

### Bearings

Since bearings are such a critical element in precision machines, one must *think* about the seemingly innumerable number of bearing design considerations that affect the performance of a machine, including:

- Speed and acceleration limits
- Range of motion
- Applied loads
- Accuracy
- Repeatability
- Sealability
- Size and configuration
- Weight
- Support equipment
- Maintenance

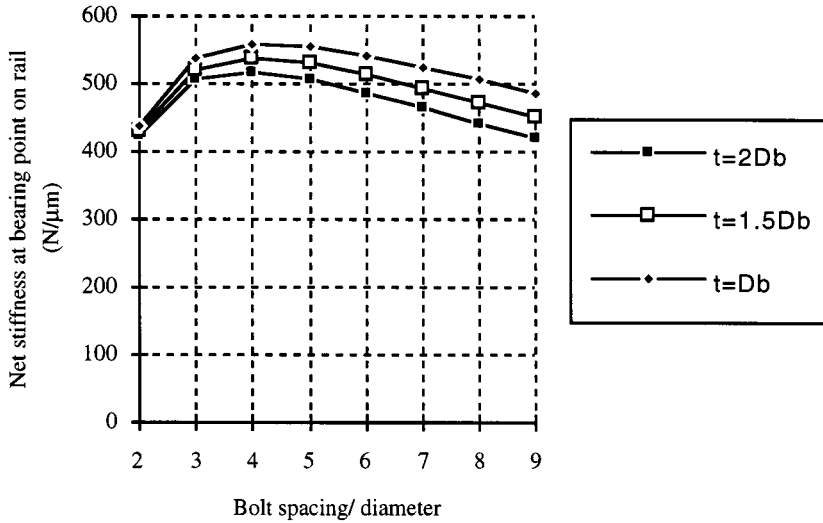

FIGURE 11.8.33 Relationships among stiffness and bolt spacing.

- Resolution
- Preload
- Stiffness
- Vibration and shock resistance
- Damping capability
- Friction
- Thermal performance
- Environmental sensitivity
- Material compatibility
- Mounting requirements
- Required life
- Availability
- Designability
- Manufacturability
- Cost

Because there are always design trade-offs in choosing a bearing for a precision machine, all of these factors must be considered simultaneously by the design engineer. In addition, there are several issues that are common to most types of bearings. These issues include surface roughness, preload, and replication of bearings in place.

**Surface Roughness**

Surface roughness is a characterization of the profile of the surface and often has an effect (although difficult if not impossible to characterize) on the smoothness of a bearing’s motion. In terms of the manufacturing process, smoothness of motion of a bearing can only be quantified in terms of the surface roughness and bearing design:

- Sliding contact bearings tend to average out surface finish errors and wear less when the skewness is negative. A positive skewness (defined below) can lead to continued wear of the bearing.
- For rolling element bearings, if the contact area is larger than the typical peak-to-valley spacing, an elastic averaging effect will occur and a kinematic arrangement of rollers will produce smooth motion. If this condition is not met, the effect will be like driving on a cobblestone street. If numerous rolling elements are used, the effects of elastic averaging can help to smooth out the motion.
- Hydrostatic and aerostatic bearings are insensitive to surface finish effects when they are considerably less than the bearing clearance.
- Flexural and magnetic bearings are not sensitive surface finish.

There are three common parameters for specifying the surface finish or roughness\*: the *root mean square* (rms or  $R_q$ ), the *centerline average* ( $R_a$ ), and the International Standards Organization (ISO) 10-point height parameter ( $R_z$ ). The latter is with respect to the five highest peaks and five lowest valleys on a sample. A surface profile measurement yields a jagged trace. If a best fit straight line is drawn through a section of the trace of length  $L$ , then the  $R_q$ ,  $R_a$ , and  $R_z$  surface finishes are defined, respectively, from deviations  $y$  from the line as a function of distance  $x$  along the sample:

$$R_q = \sqrt{\frac{1}{L} \int_0^L y^2(x) dx} \quad R_a = \frac{1}{L} \int_0^L |y(x)| dx \quad R_z = \frac{\sum_{i=1}^5 y_{\text{peak}}(i) - y_{\text{valley}}(i)}{5} \quad (11.8.29)$$

Unfortunately, these measures do not provide any information as to the topographical characteristics of the surface. As shown in Figure 11.8.34 the surface topography can be characterized by the *skewness*. The skewness is the ratio of the third moment of the amplitude distribution and the standard deviation  $\sigma$  from the mean line drawn through the surface roughness measurements. Hence the skewness provides a measure of the shape of the amplitude distribution curve. For a contact-type bearing, valleys separated by wide flat planes may be acceptable. This form would have a negative skewness value and is typically in the range  $-1.6$  to  $-2.0$  for bearing surfaces. Sharp spikes would soon grind off, creating wear debris and more damage, and hence positive skewness values are unacceptable for contact-type bearing surfaces. The skewness is defined mathematically from:

$$\text{skew} = \frac{\mu_3}{\sqrt{\mu_2}} = \frac{\mu_3}{\sigma} \quad \mu_n = \int_{-\infty}^{\infty} (y - \mu)^n f(y) dy \quad \mu = \int_{-\infty}^{\infty} yf(y) dy \quad (11.8.30)$$

FIGURE 11.8.34 Surfaces with positive (left) and negative (right) skewness.

Numerous other methods exist for defining the shape and intensity of surface roughness features. For example, the autocorrelation function is used to check for the degree of randomness in a surface. This can be used to help track down periodic components (e.g., those caused by tool chatter), which can then sometimes be reduced in subsequently made parts. A frequency spectrum analysis can also be used to accomplish this. The science of surface metrology is constantly evolving as surface finish requirements increase, and the interested reader should consult the literature.\*\*

\* See, for example, Stout, K. May 1980. How smooth is smooth. *Prod. Eng.* The following discussion on surface roughness is derived from this article. For a detailed discussion of this subject, see *Surface Texture (Surface Roughness, Waviness, and Lay)*, ANSI Standard B46.1-1985, American Society of Mechanical Engineers, 345 East 47th St., New York, NY 10017. \*\* See, for example, *Journal of Surface Metrology*, edited by K. Stout and published by Kogan Page, London.

## Bearing Preload

A preloaded bearing is one where one bearing pushes against another, thereby squeezing the bearing rail. This allows the bearing to resist bi-directional loads without motion nonlinearity (e.g., backlash) when the load reverses direction. As the force on a pair of opposing pads preloaded against each other is applied, one bearing pushes harder on the rail by an amount equal to the product of the pad stiffness and the carriage deflection, and one pushes less by the same amount.

Insufficient preload is synonymous with at least some of the bearing points periodically losing contact with the bearing surface. This results in difficult-to-map error motions and decreased stiffness, possibly leading to chatter of the tool. Tool chatter, in turn, degrades the surface finish of the part. However, with contact-type bearings, preload can accelerate wear and can lead to stiction, which decreases controllability. These issues lead to the desirability of externally pressurized fluid film bearings (air or fluid) where preload will not change with time.

Unless the axes of the machine are designed to utilize the weight of the machine itself as a preload, in many cases the preload will change with time. This is particularly true if contact-type bearing surfaces wear and if the structure relaxes, due to internal stress needed to maintain the preload. In an effort to counter these effects, the classic method has been to use a device known as a gib to generate the preload. In general, a gib can be defined as a mechanical device that can apply preload to a bearing. In the classical sense, a gib was a wedge-shaped part that was advanced by the action of a screw. When a gibbed machine wears, the gibs, bearings, and sometimes the ways must be rehand-finished and the gibs adjusted to provide the proper preload.

In many machines it is common to use modular rolling bearing components whose preload is set by using oversized balls or rollers, or by tightening bolts that push on a plate contacting the rollers. When the latter type of system wears, it is often discarded and replaced with a new unit. Hence large economies of scale can be obtained by some bearing component manufacturers.

## Replicated Bearings\*

Replication is a process whereby a very low shrinkage polymer is poured or injected around a master shape that has been coated with mold release. When the polymer cures, it has the shape of the master, which can then be removed and used again. This process can be used to form a bearing surface itself, such as a sliding bearing or a hydrostatic bearing with a pocket, or to form a mating surface between a modular bearing carriage and rough surface of a structure such as a casting.

Because hardening of many polymer resins is an exothermic reaction, one of the important aspects of this process is to minimize the amount of polymer used, and to maximize the stiffness and thermal diffusivity of the master and the part. This is required to prevent the heat of polymerization from heating the structure, deforming it, and then the polymer hardening to the thermally deformed shape. Unlike bolted assemblies, once the polymer cures to form the desired shape (e.g., a trough in which a linear bearing rail is placed), alignment is no longer possible.

Figure 11.8.35 shows schematic details of surface preparation required to ensure the debonding does not occur. This sawtooth pattern can be obtained in a number of different ways. In addition to the rough surface finish required, the surface must also be thoroughly cleaned and a mold release applied to the master.

## Sliding Contact Bearings

Sliding contact bearings are the oldest, simplest, least expensive bearing technology, and they still have a wide range of applications, from construction machinery to machines with atomic resolution. Sliding bearings are thus a very important element in the machine design engineer's tool kit. Sliding contact bearings utilize a variety of different types of lubricants between various interface materials. Lubricants

---

**FIGURE 11.8.35** Details of surface and region for replication (dimensions are in mm).

range from light oil to grease to a solid lubricant such as graphite or a PTFE polymer. Because they often distribute loads over a large area, contact stresses and space requirements are often low, while stiffness and damping are usually high. In this section, general properties of sliding contact bearings are discussed followed by a discussion of design considerations.

There are numerous types of sliding contact bearings available and in the context of discussing their general properties, some specific categories will be discussed. In general, one should note that all sliding contact bearings have a static coefficient of friction that is greater (to some degree, no matter how small) than the dynamic coefficient of friction (static  $\mu >$  dynamic  $\mu$ ). The difference between the static and dynamic friction coefficients will depend on the materials, surface finish, and lubricant.

**Rolling Element Bearings**

Figures 11.8.36 and 11.8.37 show representative types of ball and roller bearings. Typical linear rolling element bearing configurations are shown in Figure 11.8.38. Note that, in general, it is easier to make a ball spherical than a roller cylindrical; hence ball bearings are more commonly used in precision machines than are roller bearings, the exception being when very high loads must be withstood. A good roller bearing may be better than a moderate ball bearing, and hence in the end the most important thing is to compare manufacturers' specifications.

**FIGURE 11.8.36** Typical ball bearing configurations for rotary motion bearings.

For linear motion applications, it is more difficult to maintain quality control of a curved surface a ball rides on than a planar surface a roller rides on because the latter can be self-checking. Note that machine-made linear bearing rails will have the same errors as the linear bearings on the machine that

**FIGURE 11.8.37** Typical roller bearing configurations for rotary motion bearings.

**FIGURE 11.8.38** Typical linear rolling element bearing configurations.

was used to make them. For rotary axes, the raceway and the grinding tool can both be rotating at different speeds, which, combined with the random nature of precision spindle radial error motions, means that the form of the raceway can be uniform around its circumference. Thus rotary motion rolling element bearings can be made more accurate than linear motion rolling element bearings. Typical total radial error motion on a precision spindle is on the order of  $1/4$  to  $1 \mu\text{m}$ . For higher-performance linear or rotary motion bearings, one would typically move into the realm of aerostatic, hydrostatic, or magnetic bearings.

The design and production of a rolling element bearing requires careful analysis, materials selection, manufacturing quality control, and testing. Few companies other than bearing manufacturers have the resources for this type of effort. Whenever possible, one should use off-the-shelf bearing components. In addition, whenever possible, one should use modular components such as spindles and linear axes, particularly for nonsubmicron machines made in small lots (less than about 10 to 20 machines). The savings in design time, prototype testing, spare parts inventory, and repair and replacement costs often far outweigh the potential of saving a few dollars in manufacturing costs.

Designing with rolling element bearings can be intimidating because there are so many subtle details that can ruin a design if they are not considered. The best way to learn about how to handle these details is to think carefully about the physics of their design and the application and/or to work with others with experience, and if possible to experiment. In addition, manufacturers of precision bearing components are also usually willing to work with design engineers to integrate their bearing components into a design. Mapping and metrology frames can be used to increase accuracy given adequate repeatability, resolution, and controllability of the machine *if* the machine is designed with these error-reducing methods in mind.

### Rolling Element Linear Motion Bearings

After the rotary motion rolling element ball bearing, the linear motion rolling element bearing ranks on the list of major inventions. Although not found in consumer products with anywhere near the frequency

of rotary ball bearings, linear rolling element bearings are vital for the manufacturing industry. They are critical elements in the design of today's high performance machine tools and factory automation systems.

### Flexural Bearings\*

Sliding, rolling, and fluid film bearings all rely on some form of mechanical or fluid contact to maintain the distance between two objects while allowing for relative motion between them. Since no surface is perfect and no fluid system is free from dynamic or thermal effects, all these bearings have an inherent fundamental limit to their performance. *Flexural bearings* (also called *flexure pivots*), on the other hand, rely on the stretching of atomic bonds during elastic motion to attain smooth motion. Since there are millions of planes of atoms in a typical flexural bearing, an average effect is produced that allows flexural bearings to achieve atomically smooth motion. For example, flexural bearings allow the tip of a scanning tunneling microscope to scan the surface of a sample with subatomic resolution.\*\* There are two categories of flexural bearings, monolithic and clamped-flat-spring, as shown in Figures 11.8.39 and 11.8.40.

FIGURE 11.8.39 Monolithic flexural bearings.

FIGURE 11.8.40 Clamped (blade) flexure.

**Hydrostatic Bearings**

Hydrostatic bearings utilize a thin film of high-pressure oil to support a load. In general, bearing gaps can be rather large, on the order of 5 to 100  $\mu\text{m}$ . There are five basic types of hydrostatic bearings: single pad, opposed pad, journal, rotary thrust, and conical journal/thrust bearings. All operate on the principle of supporting a load on a thin film of high-pressure oil that flows continuously out of the bearing; hence a method is needed for supplying the pressurized oil and collecting and recirculating the oil that flows out of the bearing.

## 11.9 Robotics

---

*Leonard D. Albano*

The field of robotics is concerned with the design and development of mechanical devices that can be programmed to perform certain functions. Robots have been developed for a large variety of applications, such as material transport, automated assembly, and operations in controlled environments, such as high temperature and caustic surroundings. The semiconductor industry, for example, uses advanced robotic technology to fabricate IC chips. Many robots are simply relied on as a cost-effective alternative to human workers for certain highly repetitive tasks, such as spot welding and painting. For these applications, the robot must be able to undergo a range of accelerated motions while demonstrating the ability to position accurately its end effector. This must be done with minimum breakdowns and rapid repair. The control strategy involves solving the governing dynamic equations as the robot arm and end effector move through their operations. See Chapter 14 for further information.

## 11.10 Computer-Based Tools for Design Optimization

---

The range of computer applications in engineering design covers procedures from preliminary conceptual design to the production of manufacturing drawings and specifications (see Chapter 13). Most computer applications intended for production use can be classified into five or more major categories: analysis, computer-aided drafting and design, geometric modeling, data base management systems, and artificial intelligence. Traditional software for design optimization may be categorized as analytical applications, based on rational principles of mathematics and linear programming. Emerging computer-based tools for design optimization are an offshoot of research in artificial intelligence, capable of processing a variety of algorithmic, symbolic, deterministic, probabilistic, and fuzzy knowledge.

### Design Optimization with Genetic Algorithms

*Mark Jakiela*

#### Introduction

One broad use of computer-based tools in design is to automate the design process itself. This is commonly done by modeling a design problem (or class of design problems) as a search problem. Such a model requires a representation and a search process. A representation is some set of parameters, either continuous or discrete, which can represent every possible design with appropriate values assigned to each parameter. We can call each possible parameter setting a design, and the set of all possible designs (possibly infinite in number) is called the design space. The search process is some method to investigate the design space and find some design that is acceptable or desired. When some acceptable designs are more desirable than others, the search process can be used to perform optimization.

Traditionally, the search and optimization technique that has been used most frequently for mechanical engineering problems has been a gradient-based search with continuous variables. When this representation and search method agrees with the problem being solved (the optimization model functions should be smooth and the objective preferably unimodal), this technique works exceedingly well. Currently, however, a variety of important problems are not amenable to this well-established technique because they cannot be modeled with only continuous variables (discrete or mixed discrete problems) and/or the objective and constraint functions do not exhibit appropriate characteristics. Other techniques are therefore required.

This subsection will provide an introduction to genetic algorithms (“GAs”), a search and optimization process that mimics the natural process of evolution. First, a brief tutorial on the fundamentals of GAs is given. This is followed by several examples drawn from a range of engineering problem domains. We hope that the variety of examples demonstrates the real strength and advantage of genetic algorithms: their versatility. They can be used to address almost any type of optimization problem. Requirements for their use are discussed in the tutorial. Some general and philosophical remarks conclude the subsection.

#### Genetic Algorithm Tutorial

Genetic algorithms are a simulation of a simplified process of evolution (Holland, 1975). The fundamental object of data used by a GA is referred to as a chromosome. Some number of chromosomes exist simultaneously in a population. The GA transforms one population into a succeeding population, creating a generation of children from a generation of parents. It does this with operators that are analogous to the biological operators of reproduction, recombination, and mutation. A measure of the quality of each chromosome, analogous to the fitness of a biological organism in an environment, is created and used to probabilistically select chromosomes that will serve as parents. With an increasing number of generations, the overall (e.g., average, single best) fitness of the population increases and the diversity represented in the population decreases.

For engineering purposes (see e.g., Goldberg, 1989), the chromosome is some type of encoding of the characteristics of a possible design. There is the notion, therefore, of a genotype (chromosome space) to phenotype (design space) mapping. Consider, as a simple example, a GA that is used to evolve optimal values of a set of parameters. A chromosome might be set up as a string of binary digits (i.e., bits), with concatenated substrings being binary encodings for each parameter. This is shown in Figure 11.10.1. Each bit position can be thought of as a gene and the value found there can be thought of as an allele. The number of bits used to encode the parameter defines a resolution of the representation accuracy.

FIGURE 11.10.1 Binary chromosome representation.

Continuing with the explanatory parameter optimization example, the various processes of one iteration (i.e., generation) would proceed as follows. In a given generation, all chromosomes would be decoded, to yield possible values for the parameters. These parameters would be used in an objective function of interest to yield a value measuring the quality of that set of parameters. This objective function value is used as the fitness measure of the chromosome. The probability of choosing a chromosome to serve as a parent is influenced by its fitness value: as in nature, the fittest are more likely to reproduce. Pairs of parents are randomly chosen with these weighting probabilities and mated. Copies of the parent chromosomes (i.e., reproduction) are used to build the chromosomes of the children. This is done by performing some type of recombination operation on them.

Figure 11.10.2 shows a simple one-point crossover recombination operation. First, a crossover point is randomly selected along the length of the chromosomes. Then, the front of one chromosome is appended to the back of the other chromosome and vice versa. This creates two children from two parents. Performing crossover with all the pairs of parents will create a tentative population of children that can replace the parents. The final step is to perform mutation on these children with a very low probability. One bit per 1000, for example, can be randomly chosen and inverted in value as an aid to maintaining diversity in the population. Finally, replacing the parents with the children brings the algorithm to the next generation.

FIGURE 11.10.2 One-point crossover.

The procedure described above is commonly referred to as a “simple” GA (Goldberg, 1989) and can be thought of as a basic or canonical approach. In practice, several runtime parameters are required in its implementation. These include the probability of crossover (will two parents recombine, or will they proceed into the next generations unaltered?), the probability of mutation (on average, what fraction of genes are mutated?), a fitness scaling coefficient (an adjustment limiting the range of fitness values that

helps to prevent premature convergence), and population size (the number of chromosomes in a population). Note that a simple GA has the disadvantage of requiring a large number of function calls. This can be mitigated somewhat by using an “overlapping” population, in which a smaller number of parents will be chosen (i.e., fewer of the best) and the resulting children will replace the worst members of the parents’ population. Regardless of the amount of overlap, note that a GA requires no derivative computations; the search is directed by the zeroth-order sampling of fitness function values. Because of this, a GA can perform well in ill-behaved multimodal search spaces (see Goldberg, 1989) and is relatively unlikely to become trapped in local suboptima. Equally important is the high degree of general flexibility of a chromosome representation. Although a binary encoding makes clear the general operation mechanisms and actually is used for a variety of problems, several other types of representations have been used and found to work well. In almost all cases, the evolutionary optimization strategy succeeds in producing improved designs. A variety of representations and fitness/objective functions will be described in the following examples.

**Examples**

*Truss Parameter Selection.* As a first example, we describe a problem that could readily be formulated as a continuous optimization problem (see Arora, 1989, pp. 23–31). The following genetic algorithm formulation, condensed from Wallace et al. (1995), will highlight the different approaches that are needed for a GA-based optimization.

Consider the symmetric truss shown in Figure 11.10.3. The truss is to be made of medium strength structural steel. We will assume that the load  $W$  and the truss height  $h$  are specified. The designer wishes to determine the truss base  $s$  and the inside and outside diameters of the members 1 and 2. A possible list of design variables and associated upper and lower limits for this problem are shown in Table 11.10.1. Note that the variables  $r_1$  and  $r_2$  allow the cross sections to vary continuously from solid rod stock to thin-walled pipe.

**FIGURE 11.10.3** Definition of a simple two-member truss problem (gravity is assumed to be zero to simplify buckling calculations).

**TABLE 11.10.1** Design Variables or Parameters to be Optimized in the Truss Problem

Design Variable	Limits
$d_{1(\text{outside})}$	$0 < d_{1(\text{outside})} < 100 \text{ mm}$
$r_1 = d_{1(\text{inside})}/d_{1(\text{outside})}$	$0 < r_1 < 1$
$d_{2(\text{outside})}$	$0 < d_{2(\text{outside})} < 100 \text{ mm}$
$r_2 = d_{2(\text{inside})}/d_{2(\text{outside})}$	$0 < r_2 < 1$
$s$	$1000 \text{ mm} < s < 3000 \text{ mm}$

In a continuous gradient-based formulation, the next step would be to model the relationships of interest as objective and constraint functions. Lagrange variables could then be introduced and the lagrangian would be subjected to the first- and second-order (constrained) optimality conditions to find a set of local optima. In addition to the upper and lower variable limits already listed, the other relationships of interest would include the normal stresses in members 1 and 2, the buckling stress in member 1, and the material cost as the objective function.

A genetic algorithm formulation does not use any derivatives. Instead, an objective function augmented with penalty terms for each potentially active constraint is used in an unconstrained optimization search. Wallace et al. (1995) formalize the notion of “design specifications” as a means to formulate such GA design optimization problems in a consistent and simplified way. The basic idea is that specifications indicate the probability that a particular performance level will be deemed acceptable. For the truss optimization the performance specifications considered are shown in Table 11.10.2. It is also possible to use other goal, objective, or preference formulations, such as the utility theory (Keeney and Raiffa, 1976).

The performance specifications on normal stress in the two members,  $n_{\sigma_1}$  and  $n_{\sigma_2}$ , are modeled as safety factors. The specification distribution indicates that a safety factor for either member less than 1.5 is unacceptable (i.e., it will be accepted with a probability of zero, also see discussion below), and a safety factor greater than 2.0 is acceptable with certainty. To actually use this probabilistic specification, the design variables shown in Table 11.10.1 are decoded from a chromosome and used to compute values for  $n_{\sigma_1}$  and  $n_{\sigma_2}$ , resulting in turn in two acceptance probabilities. A buckling safety factor for member 1 is treated in a similar manner (note that member 2 is always in tension). In addition to the upper and lower limits on  $r_1$  and  $r_2$ , an additional performance specification is provided that indicates a strong preference for solid rod or thin-walled tube. This specification has, in effect, made the acceptable ranges of  $r_1$  and  $r_2$  discontinuous. Finally, the cost objective function is also provided to the problem as a probabilistic specification. If a full acceptance probability is achieved, the problem can be resolved with a lower material cost certainty point. In the solutions presented below, we assume that rod is 1/2 the price of pipe on a unit volume basis.

Once all individual acceptance probabilities are computed, a composite acceptance probability is used as the fitness function for the GA search. Intuitively, it seems as though the overall probability of acceptance is simply the product of the individual acceptance probabilities. Such a model does not work well in the GA-based search since a low score on a single characteristic will leave the overall design with a zero acceptance probability (in this case, the GA will consider “infeasible” designs with  $r_1$  and/or  $r_2$  between 0.2 and 0.7). The other characteristics of the designs could be very good and worthy of consideration in future generations. We therefore transform the multiplicative probability maximization into an additive information content minimization by taking the log of each probability term. The resulting objective is a generalized form of Suh’s “Information Axiom” see Section 11.4.

$$I = \sum_{i=1}^n \log_2 \left( \frac{1}{p_i} \right) \quad (11.10.1)$$

where

$n$  = number of design specifications or criteria

$p_i$  = probability of being acceptable as defined by the  $i^{\text{th}}$  specification\*

$I$  = design information content in bits

Results for the solved truss problem are shown in Figure 11.10.4. Member 1 is under compression and thus is tubular (for buckling stiffness), while the tensile member 2 is made of less expensive rod stock. Convergence to a solution typically occurred in 80 generations requiring 2.5 sec on a Silicon Graphics

\* For small values of  $p_i$ , a minimum nonzero value is used in Equation 11.10.1 to prevent division by zero.

**TABLE 11.10.2 Performance Specifications and Distributions for the Truss Problem**

Performance Specifications	Specification Distribution
$n_{\sigma_1}$ (normal stress safety factor), member 1 $n_{\sigma_2}$ (normal stress safety factor), member 2	<p>The graph shows the probability of acceptance for the stress safety specification. The x-axis is 'Normal Stress Safety Factor' ranging from 0.0 to 3.0. The y-axis is 'Probability of Acceptance' ranging from 0.0 to 1.0. The curve is zero for safety factors below 1.5. At 1.5, it begins to rise linearly, reaching a probability of 1.0 at a safety factor of 2.0. For safety factors greater than 2.0, the probability of acceptance remains at 1.0.</p>
$n_{\beta_1}$ (buckling safety), member 1	<p>The graph shows the probability of acceptance for the buckling safety specification. The x-axis is 'Buckling Load Safety Factor' ranging from 0.0 to 4.0. The y-axis is 'Probability of Acceptance' ranging from 0.0 to 1.0. The curve is zero for safety factors below 2.0. At 2.0, it begins to rise linearly, reaching a probability of 1.0 at a safety factor of 2.5. For safety factors greater than 2.5, the probability of acceptance remains at 1.0.</p>
C (cost)	<p>The graph shows the probability of acceptance for the material cost specification. The x-axis is 'Material Cost (monetary units)' ranging from 0.0 to 400.0. The y-axis is 'Probability of Acceptance' ranging from 0.0 to 1.0. The curve is at a probability of 1.0 for costs up to 50.0. From 50.0 to 300.0, the probability of acceptance decreases linearly from 1.0 to 0.0. For costs greater than 300.0, the probability of acceptance is 0.0.</p>

**TABLE 11.10.2 Performance Specifications and Distributions for the Truss Problem (continued)**

Performance Specifications	Specification Distribution
$r_1$ (diameter ratio), member 1	
$r_2$ (diameter ratio), member 2	

**FIGURE 11.10.4** (a) Configuration of the optimized truss design.

Indigo<sup>2</sup> Extreme<sup>2</sup>. This search involved the evaluation of 2400 candidate designs (30 per generation). The search space for this problem contains  $\approx 1.1 \times 10^{12}$  points (five parameters at 8-bit resolution gives  $2^{40}$  points).

It must be noted that the search converged to this solution using rod stock for member 2 in only 17% of 60 consecutive optimizations. The more frequent solution shown in [Figure 11.10.5](#) is nearly as good.

*Topology Optimization.* In this example, we will address planar stress/strain problems and the generation of optimal structural topologies. As shown in [Figure 11.10.6](#), a design domain defines the allowable extents of any possible design. This domain is discretized into a rectangular grid, with each square element of the grid assigned a value of “material” or “void”. Treating each grid element as a binary variable leads to a large combinatorial search space. The grid is used to create a finite element mesh for structural analysis. In our case, each material element contains four triangular finite elements made from the five nodes located at the four corners and the center of each material element. The genotype corresponding to this phenotype is a simple binary two-dimensional array chromosome, or a binary string, as described below.

Phenotypically, certain material elements are required to always contain material, regardless of the bit value in the genome. We refer to these as material constraints. These are elements that serve as structural boundary conditions. In [Figure 11.10.6](#), examples would be the highest and lowest elements bordering the wall, and the element that is used to apply the load. Thus, the genotype is not always a completely accurate representation of the actual structure.

$n_{\sigma_1} = 7.09, p_{\text{acceptable}} = 1.0$

$n_{\sigma_2} = 2.03, p_{\text{acceptable}} = 1.0$

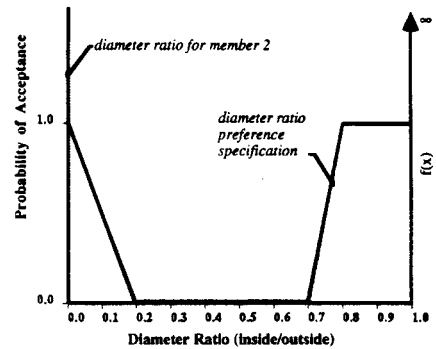

$n_{B1} = 2.50, p_{\text{acceptable}} = 1.0$

$C = 51.02 \text{ units}, p = .9958$

$r_1 = 0.9764, p_{\text{acceptable}} = 1.0$

$r_2 = 0.0, p_{\text{acceptable}} = 1.0$

FIGURE 11.10.4 (b) Comparison of truss performance variables to design specifications.

The genotype can also differ from the phenotype because of connectivity analysis. Connectivity analysis requires that all elements that are included in the structural analysis be connected to other elements by at least one edge–edge connection, as opposed to only a corner connection. In addition, all elements considered connected must be linked to one of the material constraint elements by a path of edge connections. Any elements not so connected are removed from the mesh for the purposes of structural analysis: they are considered to have no stiffness and no mass. Since we are addressing planar problems, the rationale for connectivity analysis is that elements connected at corners cannot transfer

**FIGURE 11.10.5** A result that did not find the better solution using cheaper rod stock for member 2. The cost is 56.73 units, giving  $p_{\text{acceptable}} = 0.9728$  (compared to 0.9958 for the solution using rod for member 2).  $n_{\sigma_1} = 7.49$ ,  $n_{\sigma_2} = 2.01$ ,  $n_{p_1} = 2.50$ .

**FIGURE 11.10.6** Typical design domain.

moments about those corners (since the finite element model treats corners as kinematic pin joints). It is less likely, therefore, that “disconnected” elements will contribute to enhanced structural performance. We have found that this is true empirically (see Chapman et al., 1993 for further discussion of this topic). Figure 11.10.7 shows the structure of Figure 11.10.6 after connectivity analysis. It is important to note that we do not penalize structures with more disconnected elements; we simply reward structures based upon the performance caused by their connected elements. This allows disconnected elements to in some sense be “recessive”, in that crossover could cause them to combine with the (possibly disconnected) elements from another structure to yield a structure of connected elements of much improved performance.

As fitness, we are interested primarily in structural performance. In this study, this will be represented by two characteristics, mass and deflection. Generally, we wish the genetic algorithm to evolve structures that are both lightweight and deflect small amounts under a given load. The deflection,  $\delta$ , will be measured with a finite element simulation and the mass  $m$  will be proportional to the number of connected material elements. These two characteristics can be used to create an unconstrained fitness, such as maximizing the following ratio:

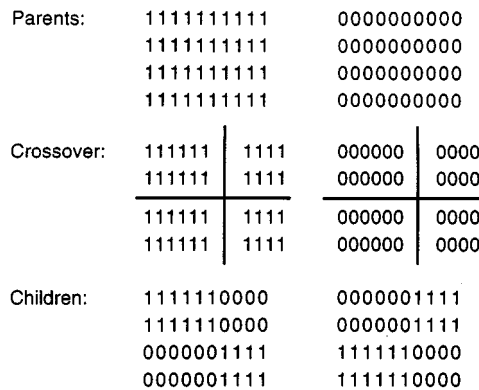

$$\text{fitness} = \frac{1}{(\delta)(m)} \tag{11.10.2}$$

**FIGURE 11.10.7** After connectivity analysis.

Alternatively, one of these characteristics can be optimized while treating the other as a constraint. Chapman and Jakiela (1995) provide some guidelines for using penalty functions for structural optimization that address many different characteristics (e.g., reducing the number of macroscopic holes in the topology).

In this example, we will use two different types of chromosomes to represent the material array. The first is a one-dimensional string chromosome made by concatenating the rows of the material array. The second is a two-dimensional binary array precisely matching the material array. For a two-dimensional array chromosome, a single-point crossover can be done as shown in Figure 11.10.8. A position is randomly selected along both dimensions, defining a point in the array. Complementary parts from both parents, diagonal about the point, contribute to the chromosomes of the children. Note that this approach can be extended to any dimension.

**FIGURE 11.10.8** One-point crossover on 2D arrays.

Using the binary string chromosome, Figure 11.10.9 shows results for three different material discretizations. The loading and material constraints were as described in Figure 11.10.6. All three cases display a uniformly distributed porosity with an overall shape arising implicitly from the topological optimization.

*Hierarchical Shape Packing.* Effective material utilization is important to virtually all industries. A specific problem in this area that can be modeled as a combinatorial optimization problem is the arrangement of planar shapes to be cut out from a piece of material so as to minimize scrap. This problem has great economic significance in the garment, sheet metal, shipbuilding, and other industries. A common instance involves a “blank” of stock material of fixed width, such as would result from a roll of material.

**FIGURE 11.10.9** Results of (a)  $10 \times 16$ , (b)  $15 \times 24$ , and (c)  $20 \times 32$  optimizations.

The part shapes must be arranged to minimize the length of material required from the roll. We have solved this problem with a two-level hierarchical genetic algorithm. A more complete description of this approach can be found in Dighe and Jakiela (1995a).

The approach of the lower level is shown in Figure 11.10.10. The blank of fixed width is considered analogous to a box into which the shapes will be packed. One by one, in a particular order, the shapes will be placed into the box so as to minimize the accrued height required. To pack a particular shape, a location and orientation is specified, as shown in Figure 11.10.10b, and the shape is “dropped” straight down until it contacts one of the previously packed shapes or the bottom of the box. The “dropping into a box” metaphor does not extend to include dynamic effects. Note, for example, that part D in Figure 11.10.10c would not rotate and slide to settle in a lower final position; it is in its final location for the values of  $x$  and  $\theta$  chosen. Figure 11.10.10d shows a much better choice of parameters for  $x$  and  $\theta$ . The lower level uses a genetic algorithm to optimize the values of  $x$  and  $\theta$  and therefore is used each time a shape is packed.

The overall success of this packing strategy depends on the order in which the objects are placed. The higher-level GA searches the space of possible orders to find those that work well with the packing strategy of the lower-level GA. The chromosome representation for a packing order, and associated crossover and mutation operators are shown in Figure 11.10.11. The chromosome is simply a list of part labels, with the left-to-right order indicating the packing order. If we try to perform a single point crossover on these strings, Figure 11.10.11 shows that invalid offspring often result. Some labels are missing and others appear more than once. To remedy this problem, we use a simple order-based crossover as shown in Figure 11.10.11b. For positions to the left of the crossover point, each child receives the order from one of the parents. The order of the remaining parts is obtained from the order in which those remaining parts appear in the other parent’s chromosome. Finally, mutation simply changes the location of a part label, usually by moving it to the left.

Note that this crossover operator tends to not disrupt the leftmost parts of the chromosomes. In particular, without mutation, the very leftmost position in any chromosome must have a label that was present in that position in the initial population. Hence, mutation is performed with a leftward bias.

Figure 11.10.12 shows some typical arrangements produced using this approach. Figures 11.10.12a and 11.10.12b show two configurations in the same optimization run. These ten objects were chosen such that their characteristic sizes varied by about a factor of 10. Figure 11.10.12 shows a jigsaw puzzle that we have used as a benchmark test for the packing system. Taking into account deliberate gaps between the parts, the density of the correct jigsaw arrangement is 0.92, not 1.00. Two arrangements from the same optimization run are shown in Figures 11.10.12d and 11.10.12e. It is clear that the simple “height-based” lower-level GA cannot match a human’s visual processing and reasoning ability.

**FIGURE 11.10.10** Lower-level GA for hierarchical shape packing.

Integrating a GA-based search with heuristics derived from observation of human experts is the subject of ongoing work in this area (see Dighe and Jakiela, 1995b).

## Optimization in Multidisciplinary Design

*Kemper Lewis, Farrokh Mistree, and J. R. Jagannatha Rao*

### Introduction

The design of complex systems is a difficult task of integrating disciplines, each with their own analysis, synthesis, and decision process. Optimizing such a system on a global scale is realistically impossible, but finding a solution that is “good enough” and robust is achievable. Several approaches to formulating and solving a multidisciplinary design problem have arisen in a rather ad hoc fashion since the inception of multidisciplinary design optimization (MDO). These approaches include single-level and multilevel formulations, hierarchical and nonhierarchical system decomposition methods, and numerous optimization and analysis processes and approaches at the system and subsystem levels. Designers are referred to as decision makers and objectives as goals or rewards. With only one decision maker, the problem becomes a scalar or vector optimization problem. But in MDO, many decision makers may exist, and each decision maker’s strategy to optimize his/her rewards could depend on the strategies and decisions of other decision makers. The modeling of strategic behavior based on the actions of other individuals is known as a *game*. Therefore, the focus in this section is on problems characterized by

- Single decision makers who have multiple rewards
- Multiple decision makers who have multiple rewards

This focus in optimization theory is shown as the shaded region in [Figure 11.10.13](#). Typical courses in optimization focus on the upper-left quadrant, namely, scalar optimization problems with one objective and one decision maker. In this section, the focus is on the other three quadrants as a means to expand the application of optimization theory to problems that frequently occur in engineering design.

### Classification of MDO Formulations

*Simultaneous and Nested Analysis and Design.* With the advent of MDO and its various applications, a structure of problem approaches and formulations is necessary. In Cramer et al. (1994) and, more recently, Balling and Sobieski (1994) and Lewis and Mistree (1995), various classes and classifications of problem formulations are presented. [Figure 11.10.14](#) is a generic representation of a coupled, three-discipline system.

Depending on the level of analysis, the modules in [Figure 11.10.14](#) may refer to disciplines, components, or processes. It is the decomposition of the system, subsystem coupling and solution, and system synthesis that pose major research and application problems in MDO. The terms used in the figure, as well as other common terms, are defined below.

$s_1, s_2, s_3$ : disciplinary *state variables* which comprise the *state equations*

$y_1, y_2, y_3$ : the *state equations*

$r_1, r_2, r_3$ : *residuals* in the state equations

$y_{12}, y_{13}, y_{21}, y_{23}, y_{31}, y_{32}$ : *coupling functions*,  $y_{ij}$  contains those functions computed in discipline  $i$  which are needed in discipline  $j$

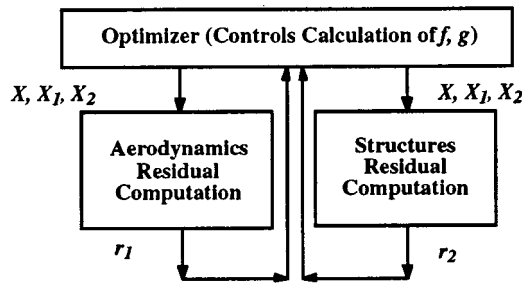

FIGURE 11.10.15 Single-SAND-SAND formulation.

$y_{12}^*, y_{13}^*, y_{21}^*, y_{23}^*, y_{31}^*, y_{32}^*$ : coupling variables  
 $x$ : system design variables needed by more than one discipline  
 $x_1, x_2, x_3$ : disciplinary design variables  
 $g_1, g_2, g_3$ : design constraint functions  
 $f_1, f_2, f_3$ : design objective functions

The primary task at hand is summarized as follows: *Determine the values of the design, state, and coupling variables which satisfy the state equations, the coupling equalities, the design constraints, and the design objective functions.*

Based on this, six classifications for fundamental approaches to MDO problem formulation and solution are presented by Balling and Sobieski, which depend on three criteria:

1. System vs. multilevel decomposition
2. Simultaneous (SAND) vs. nested analysis and design (NAND) at the *system* level.
3. Simultaneous (SAND) vs. nested analysis and design (NAND) at the *subsystem* or *discipline* level.

At the discipline level, SAND implies that the disciplinary design and state variables are determined simultaneously by the optimizer, while NAND implies that the optimizer determines only the disciplinary design variables and requires determination of the state variables at each iteration. At the system level, SAND implies that the system design variables and coupling variables are determined simultaneously by the system optimizer, while NAND implies that the system optimizer determines only the system design variables and requires calls to a system analysis routine to determine the coupling variables at each iteration. The “optimizers” at the system level or discipline level could be gradient based or heuristic in nature, depending on the problem formulation. Further classifications can be generated if these approaches are combined or linked sequentially within one design problem.

Each approach has a three-part name consisting of the overall decomposition descriptor, the solution approach at the system level, and the solution approach at the subsystem level. The first part indicates whether the approach is a single-level or multilevel approach. The middle and last parts of the name indicate whether the SAND or NAND approach is used at the system and discipline levels, respectively.

### Example

These terms are illustrated based on a simple example from aeroelastic MDO problem in Cramer et al. (1994). This aeroelastic problem involves two disciplines, aerodynamics and structures. This problem is extremely difficult, as the solution of either of these disciplines *alone* involves heavy analysis and computation. For simplicity, it is assumed that a *single-level* scheme is to be used. The first formulation choice is SAND or NAND at the system level. If a SAND formulation is used, the discipline-level formulation must be determined. These formulations are illustrated below.

*Single-SAND-SAND.* In this formulation, feasibility is *not* sought for the analysis problem in any sense until convergence in the solver is reached. The analysis “codes” for aerodynamics and structures in this formulation perform a simple function; they evaluate the *residuals* of the analysis equations, rather than solving some set of equations. This is illustrated in [Figure 11.10.15](#). The *optimizer* controls the calculation of the objective functions,  $f$ , and the constraints,  $g$ , based on the residuals,  $r_i$ , from the disciplines. The optimizer sends system and disciplinary design variables,  $X$  and  $X_i$ , to the disciplinary analysis routines.

*Single-SAND-NAND.* In this formulation, feasibility *is* enforced for each individual discipline, while the optimizer drives the individual disciplines toward multidisciplinary feasibility and optimality by controlling the coupling functions between the disciplines. This is illustrated in [Figure 11.10.16](#). The optimizer sends design and coupling variables,  $X$  and  $y_{ij}^*$ , to the disciplinary analysis routines, while these routines return coupling functions,  $y_{ij}$ , which are functions of the design variables and the disciplinary state variables,  $y_i$ .

*Single-NAND-NAND.* In this formulation, multidisciplinary feasibility is required at each iteration of the optimizer. Therefore, an aeroelastic analysis solver combines the information from the aerodynamics

FIGURE 11.10.16 Single-SAND-NAND formulation.

and structures disciplines and ensures that the two disciplines are feasible concurrently. This is illustrated in Figure 11.10.17. The optimizer only controls the objective functions and constraints, while the coupling functions are handled by the aeroelastic analysis solver which becomes a “black box” from the perspective of the optimization code. In each discipline, an analysis code solves a set of equations. The resulting *state equations* are fed into the other disciplines. This process continues until convergence among the disciplines, and the optimizer is once again invoked.

FIGURE 11.10.17 Single-NAND-NAND formulation.

### Modeling Design Decisions: The Mathematical Programming Background

Decision-based design (DBD) is offered as a starting point for the creation of design methods that are based on the notion that the principal role of an engineer in the design of a product or process is to make decisions. Therefore, the process of design in its most basic sense is a series of decisions.

It is recognized that the implementation of DBD can take many forms; one implementation is the decision support problem (DSP) technique. Within the DSP technique there exist three types of decisions a designer can make: selection, compromise, or heuristic. In this section, the focus is on the compromise DSP, which is used to model multiobjective trade-offs in the solution of a mathematical model.

*Compromise DSP.* A compromise DSP is a hybrid formulation that incorporates concepts from both traditional mathematical programming and goal programming, and makes use of some new ones (Mistree et al., 1993). It is similar to goal programming in that the multiple objectives are formulated as system goals (involving both system and deviation variables) and the deviation function is solely a function of the goal deviation variables. This is in contrast to traditional mathematical programming where multiple objectives are modeled as a weighted function of the system variables only. The concept of system

constraints, however, is retained from the traditional constrained optimization formulation. Special emphasis is placed on the bounds on the system variables, unlike in traditional mathematical programming and goal programming. In effect the traditional formulation is a subset of the compromise DSP — an indication of the generality of the compromise formulation. The compromise DSP is stated in words as follows:

**Given**

An alternative that is to be improved through modification

Assumptions used to model the domain of interest

The system parameters

All other relevant information

- n      Number of system variables
- p + q   Number of system constraints
- p      Equality constraints
- q      Inequality constraints
- m      Number of system goals
- $g_i(\underline{X})$    System constraint function

$$g_i(\underline{X}) = C_i(\underline{X}) - D_i(\underline{X})$$

$f_k(d_i)$    Function of deviation variables to be minimized at priority level k for the preemptive case

$W_i$       Weight for the Archimedean case

**Find**

The values of the independent *system variables* (they describe the physical attributes of an artifact)

$$X_j \quad j = 1, \dots, n$$

The values of the *deviation variables* (they indicate the extent to which the goals are achieved)

$$d_i^-, d_i^+ \quad i = 1, \dots, m$$

**Satisfy**

The *system constraints* that must be satisfied for the solution to be feasible, there is no restriction placed on linearity or convexity

$$g_i(\underline{X}) = 0; \quad i = 1, \dots, p$$

$$g_i(\underline{X}) \geq 0; \quad i = p + 1, \dots, p + q$$

The *system goals* that must achieve a specified target value as far as possible; there is no restriction placed on linearity or convexity

$$A_i(\underline{X}) + d_i^- - d_i^+ = G_i; \quad i = 1, \dots, m$$

The lower and upper *bounds* on the system

$$X_j^{\min} \leq X_j \leq X_j^{\max}; \quad j = 1, \dots, n$$

$$d_i^-, d_i^+ \geq 0 \quad \text{and} \quad d_i^- \cdot d_i^+ = 0$$

**Minimize**

The *deviation function* which is a measure of the deviation of the system performance from that implied by the set of goals and their associated priority levels or relative weights:

Case a: Preemptive (lexicographic minimum)

$$Z = [f_1(d_i^-, d_i^+), \dots, f_k(d_i^-, d_i^+)]$$

Case b: Archimedean

$$Z = \sum_{i=1}^m W_i(d_i^- + d_i^+); \quad \sum W_i = 1; \quad W_i \geq 0$$

A graphical representation of a two-variable compromise DSP is shown in Figure 11.10.18. The difference between a system variable and a deviation variable is that the former represents a distance in the  $i^{th}$  dimension from the origin of the design space, whereas the latter has as its origin the surface of the system goal. The value of the  $i^{th}$  deviation variable is determined by the degree to which the  $i^{th}$  goal is achieved. It depends upon the value of  $A_i(X)$  alone (Since  $G_i$  is fixed by the designer), which in turn is dependent upon the system variables  $X$ . The set of discrete variables can be continuous, Boolean, or a combination of types.

FIGURE 11.10.18 The compromise DSP.

The compromise DSP is fundamentally different from the traditional mathematical optimization model. This difference is depicted in Figure 11.10.19 where the optimization model on the left occurs when designer’s aspirations can be met by the system achievement and therefore an optimum can be found. But when a designer’s aspirations do not overlap with the actual achievements, a solution which is “good enough” or *satisficing*\* must be found. This is depicted and modeled in the compromise DSP on the right of Figure 11.10.19. When the aspiration space overlaps with the feasible design space (center of Figure 11.10.19), the optimization model and compromise DSP are the same.

FIGURE 11.10.19 The optimizing and satisficing models.

*Deviation Variables and Goals.* In a **goal** one can distinguish the aspiration level,  $G_i$ , of the decision maker and the actual attainment,  $A_i(X)$ , of the goal. Three conditions need to be considered:

1.  $A_i(X) \leq G_i$ ; one wishes to achieve a value of  $A_i(X)$  that is equal to or less than  $G_i$ .
2.  $A_i(X) \geq G_i$ ; one wishes to achieve a value of  $A_i(X)$  that is equal to or greater than  $G_i$ .
3.  $A_i(X) = G_i$ ; one wishes to achieve a value of  $A_i(X)$  equal to  $G_i$ .

Next, the concept of a **deviation variable** is introduced. Consider the third condition, namely, one would like the value of  $A_i(X)$  to equal  $G_i$ . The deviation variable is defined as

$$d = G_i - A_i(\underline{X})$$

The deviation variable  $d$  can be negative or positive. In effect, a deviation variable represents the distance (deviation) between the aspiration level and the actual attainment of the goal. Considerable simplification

\* Satisficing — not the “best”, but “good enough” (the first use of this term, in the context of optimization, is attributed to Herbert Simon (Simon, 1982).

of the solution algorithm is affected if one can assert that all the variables in the problem being solved are positive. Hence, the deviation variable  $d$  is replaced by two variables:

$$d = d_i^- - d_i^+$$

where

$$d_i^- \cdot d_i^+ = 0 \quad \text{and} \quad d_i^-, d_i^+ \geq 0$$

The preceding ensures that the deviation variables never take on negative values. The product constraint ensures that one of the deviation variables will always be zero. The system goal becomes

$$A_i(\underline{X}) + d_i^- - d_i^+ = G_i; \quad i = 1, 2, \dots, m \quad (11.10.3)$$

subject to

$$d_i^-, d_i^+ \geq 0 \quad \text{and} \quad d_i^- \cdot d_i^+ = 0 \quad (11.10.4)$$

If the problem is solved using an algorithm that provides a vertex solution as a matter of course, then the constraint is automatically satisfied making its inclusion in the formulation redundant. Since some algorithms use solution schemes which provide a vertex solution, it is assumed that this constraint is satisfied. For completeness this constraint is included in the mathematical forms of the compromise decision support problem given previously in this chapter and for brevity will be omitted from all subsequent formulations.

Note that a goal (Equation 11.10.3) is always expressed as an equality. When considering Equation (11.10.3), the following will be true:

- if**  $A_i \leq G_i$  **then**  $d_i^- > 0$  and  $d_i^+ = 0$ .
- if**  $A_i \geq G_i$  **then**  $d_i^- = 0$  and  $d_i^+ \geq 0$ .
- if**  $A_i = G_i$  **then**  $d_i^- = 0$  and  $d_i^+ = 0$ .

How are the three conditions listed using Equation (11.10.3)?

1. To satisfy  $A_i(X) \leq G_i$ , the positive deviation  $d_i^+$  must be equal to zero. The negative deviation  $d_i^-$  will measure how far the performance of the actual design is from the goal.
2. To satisfy  $A_i(X) \geq G_i$ , the negative deviation  $d_i^-$  must be equal to zero. In this case, the degree of overachievement is indicated by the positive deviation  $d_i^+$ .
3. To satisfy  $A_i(X) = G_i$ , both deviations,  $d_i^-$  and  $d_i^+$ , must be zero.

At this point it is established what is to be minimized. In the next section means for minimization of the objective in goal programming are introduced.

*The Lexicographic Minimum and the Deviation Function.* The objective of a traditional single objective optimization problem requires the maximization or minimization of an objective function. The objective is a function of the problem variables. In a goal programming formulation, each of the objectives is converted into a goal (Equation 11.10.3) with its corresponding deviation variables. The resulting formulation is similar to a single objective optimization problem but with the following differences:

The objective is always to minimize a function.

The objective function is expressed using deviation variables only.

The objective in the goal programming formulation is called the achievement function. As indicated earlier the deviation variables are associated with goals and hence their range of values depend on the

goal itself. Goals are not equally important to a decision maker. Hence to effect a solution on the basis of preference, the goals may be rank-ordered into priority levels.

One should seek a solution which minimizes all unwanted deviations. There are various methods of measuring the effectiveness of the minimization of these unwanted deviations. The *lexicographic minimum* concept is a suitable approach, and it is defined as follows (see Ignizio, 1982; Ignizio, 1985).

Given an ordered array  $f = (f_1, f_2, \dots, f_n)$  of nonnegative elements  $f_k$ , the solution given by  $f^{(1)}$  is preferred to  $f^{(2)}$  iff

$$f_k^{(1)} < f_k^{(2)}$$

and all higher-order elements (i.e.,  $f_1, \dots, f_{k-1}$ ) are equal. If no other solution is preferred to  $f$ , then  $f$  is the lexicographic minimum.

As an example, consider two solutions,  $f^{(r)}$  and  $f^{(s)}$ , where

$$f^{(r)} = (0, 10, 400, 56)$$

$$f^{(s)} = (0, 11, 12, 20)$$

In this example, note that  $f^{(r)}$  is preferred to  $f^{(s)}$ . The value 10 corresponding to  $f^{(r)}$  is smaller than the value 11 corresponding to  $f^{(s)}$ . Once a preference is established, then all higher-order elements are assumed to be equivalent.

### The Use of Coupled DSPs in Modeling and Solving Systems

Coupled compromise DSPs can be used to model multiobjective problems. These types of problems may involve the analysis and synthesis of problems from multiple disciplines, but in this section, the primary notion is *shared* design variable vectors. It is common in the design of complex systems, such as aircraft, for multiple design teams to include the same design variables in their design process. For example, consider the design of aircraft. The design variable, wing area, is used by the aerodynamics group to control the lift force. It is used by the structural group to control the structural framework of the wing. It is used by the propulsion group to control the amount of fuel needed. It seems advantageous to model systems this way, but this introduces an added level of complexity in a system model. Different disciplines are also dependent on the decisions made in other disciplines. Therefore, another focus is modeling the coupling of state variables between disciplines.

To begin the discussion, suppose that a designer (i.e., a decision maker) is investigating a typical engineering system such as a load-bearing structure, a high-speed mechanism, or an automotive transaxle. Assuming that this system is unambiguously described by a finite-dimensional variable vector  $x \in \mathcal{R}^n$  (includes both the so-called “state” and “design” variables), then the general descriptive mathematical model can be characterized by a set of *parameters*  $p$ , which are fixed quantities over which the designer has no control, and the multifunction  $X$ , which represents the state equations and variational inequalities (derived from the natural laws such as the conservation principles) as well as the performance constraints for this system. Numerical approaches to such problems have been studied in Outrata (1990) and Outrata and Zowe (1995). If the only goal of the designer is to obtain a satisfying or a feasible design, then his/her task is simply to find a design  $x^o$  that satisfies the constraints and meets the goals as close as possible for a given  $p$ . On the other hand, if the designer wishes to find the design which minimizes the deviation between the goal achievement and aspiration with respect to several objective functions such as  $f_i(x, p)$ ,  $i = 1, \dots, r$ , then the problem is to find a design  $x^*$  that solves the following multiobjective formulation:

$$\text{minimize}_{x \in X(p) \subset \mathbb{R}^n} d(x, p) = \{d_1(x, p), \dots, d_r(x, p)\} \quad (11.10.5)$$

where  $d_i$  represents the deviation from the objective  $f_i$  to its target value,  $f_{iTV}$ . In other words, the problem is to minimize the deviation between what a designer wants and what a designer can achieve.

At this general level of discussion, one readily asserts that a model such as in Equation (11.10.5) is the typical starting point for much of the current education, research, and practice in mechanical systems modeling and applied optimization, and yet in specific design instances, this assertion should be boldly challenged. For example, since the designer only controls  $x$  and another foreign party controls  $p$ , how is  $p$  chosen? Can the designer assume that the foreign decision maker will always select the vector that is most advantageous to the design (as is tacitly assumed, it is argued later, by most justifications of existing engineering models)? If not, how should the designer respond to this conflict? A two-player strategic game has just been described (see, e.g., Von Neumann and Morgenstern, 1944; Aubin, 1979; Dresher, 1981) where one player controls  $x$  and the other player controls  $p$  and where  $p$  represents all decisions which are outside the scope of the designer. By the classical definition, a “game” consist of multiple decision makers or players (or designers, in this case) who each control a specified subset of system variables and who seek to minimize their own deviation functions subject to their individual constraints. To continue this argument further, consider a typical schedule of a product design and manufacture, as shown in Figure 11.10.20.

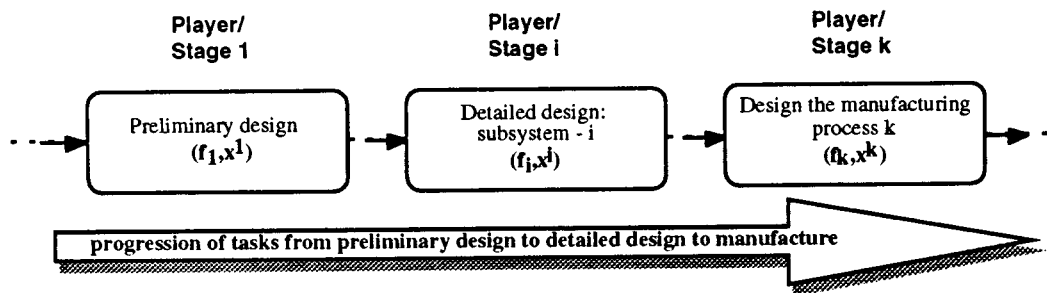

FIGURE 11.10.20 Different stages in a design time-line.

The decision makers at each of the several stages or stations in the time line are referred to as different players, even though they could be the same human designer. Each of the players controls and minimizes his own deviation function.

In the context where multiple decision makers collectively influence the final design, one must pose the following question: what mathematical formulation is appropriate for modeling the system in order to study the decisions made by *more than one player along the above time line*? Clearly, the conventional model of Equation (11.10.5) does not adequately represent the multiplayer scenario of the time line shown in Figure 11.10.20. This inadequacy is most acute when the players engage in strategic behavior which is anything other than total cooperation (e.g., dominance and noncooperation, among others). Thus, the major point of departure can be summarized as: (1) instead of formulating a single mathematical model at a single stage of the time line, as is done conventionally, these models represent one or more decision makers who determine the final design; and (2) each of the  $r$  decision makers has his own objective functions and one player's decision is influenced by the other. Thus, the final design could very well depend on whether the players compete, cooperate, or dominate one another — thus necessitating a study of the strategic interaction between the players. In short, a goal here is to model the design of Figure 11.10.20 as a *strategic game*, this figure perhaps being representative of a general engineering system design process at a high level of abstraction.

Mathematical modeling of such strategic behavior, where one decision maker's action depends on decisions by others, is well-established in wide-ranging applications from economics, business, and military (Aubin, 1979; Dresher, 1981; Fudenberg and Tirole, 1991; Mesterton-Gibbons, 1992). Such models are widely used in designing markets and auctions, and in predicting the outcome of encounters between competing companies or trading nations. As specific examples, consider automobile manufac-

turers who interact strategically in order to set prices and production schedules of cars; or the strategic behavior that occurs between drivers as they try to pass each other on a busy undivided highway.

### **Introduction — Nature and Properties of Pure Metals**

Metals achieve engineering importance because of their abundance, variety, and unique properties as conferred by metallic bonding. Twenty-four of the 26 most abundant elements in the Earth's crust are

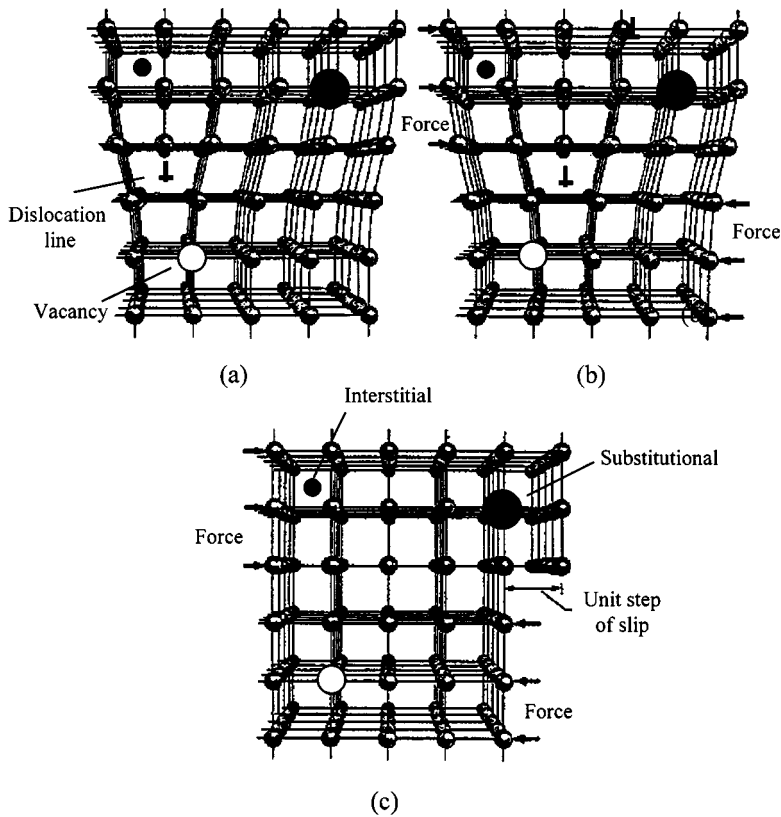

metals, with only two nonmetallic elements, oxygen and silicon, exceeding metals in frequency. The two most abundant metallic elements, iron (5.0%) and aluminum (8.1%), are also the most commonly used structural metals. Iron is the most-used metal, in part because it can be extracted from its frequently occurring, enriched ores with considerably less energy penalty than aluminum, but also because of the very wide range of mechanical properties its alloys can provide (as will be seen below). The next 15 elements in frequency, found at least in parts per thousand, include most common engineering metals and alloys: calcium (3.6%), magnesium (2.1%), titanium (0.63%), manganese (0.10), chromium (0.037%), zirconium (0.026%), nickel (0.020%), vanadium (0.017%), copper (0.010%), uranium (0.008%), tungsten (0.005%), zinc (0.004%), lead (0.002%), cobalt (0.001%), and beryllium (0.001%). The cost of metals is strongly affected by strategic abundance as well as secondary factors such as extraction/processing cost and perceived value. Plain carbon steels and cast irons, iron alloys with carbon, are usually most cost-effective for ordinary mechanical applications. These alloys increase in cost with alloying additions.

A variety of metal properties are unique among materials and of importance technologically. These properties are conferred by metallic bonding, in which the “extra” outer valence electrons are “shared” among all metal ion cores. This bonding is different from other types of solids in that the electrons are free to acquire energy, and the metallic ions are relatively mobile, and quite interchangeable with regard to their positions in the crystal lattice, the three-dimensional repeating arrangement of atoms in a solid. This section of the chapter will concentrate on the mechanical properties of metals, for which metallic bonding provides ductile deformation, i.e., shows substantial permanent shape change under mechanical load prior to fracture. The ductility of metals at low and moderate temperature makes them formable as solids and also confers safety (fracture toughness) in mechanical applications, in that under impact loading the metal will absorb energy rather than break catastrophically.

Metals are good conductors of heat and electricity because thermal and electrical energy can be transferred by the free electrons. These two properties tend to parallel each other. For example, the pure noble metals (e.g., copper, silver, gold, platinum) are among the best electrical and thermal conductors. As a broad generalization, metallic elements with an odd number of valence electrons tend to be better conductors than those with an even number. These behaviors can be seen in Table C.6A of the Appendix. Thermal conductivity and electrical resistivity (inverse conductivity) have a reciprocal relationship and follow the indicated trends. As metals are alloyed with other elements, are deformed, contain multiple phases, and contain crystalline imperfections, their electrical and thermal conductivity usually decreases significantly from that of the pure, perfect, unalloyed metal. The specific values of thermal conductivity and electrical resistivity for several common engineering alloys is given in Table C.6B of the Appendix. Electrical and thermal conductivities tend to decrease proportionately to each other with increasing temperature for a specific metal. These conductivities may be altered if heating introduces metallurgical change during annealing (see subsection on mechanical forming).

Metals are opaque to and reflective of light and most of the electromagnetic spectrum, because electromagnetic energy is transferred to the free electrons and immediately retransmitted. This gives most metals a characteristic reflective “metallic color” or sheen, which if the metal is very smooth yields a mirror surface. At very short wavelengths (high energies) of the electromagnetic spectrum, such as X rays, the radiant energy will penetrate the material. This is applied in radiographic analysis of metals for flaws such as cracks, casting porosity, and inclusions.

Metals are almost always crystalline solids with a regular repeating pattern of ions. A number of atomic-level defects occur in this periodic array. A large number of atomic sites are “vacancies” (point defects) not occupied by atoms (Figure 12.1.1). The number and mobility of vacant sites increase rapidly with temperature. The number and mobility of vacancies in metals are quite high compared with other materials because there are no charge balance or local electron bond considerations. This means that solid metal can undergo significant changes with only moderate thermal excitation as vacancy motion (diffusion) provides atom-by-atom reconstruction of the material. Vacancies allow solid metals to homogenize in a “soaking pit” after casting and permit dissimilar metals to diffusion bond at moderate temperatures and within short times. In the process, substitutional metallic atoms (ions) shown in Figure

**FIGURE 12.1.1** Point defects exist in the metal crystal structure: vacancies, substitutional atoms (ions), ions, and interstitial atoms (ions). A dislocation ( $\perp$ ) line moves under an applied shear force until a surface step of plastic deformation is produced on the surface.

12.1.1 move via vacancy jumps while small interstitial atoms such as carbon (Figure 12.1.1) move from interstice to interstice. Vacancy mobility gives rise to major changes in mechanical properties during annealing (see subsection on mechanical forming) and is an important mechanism in creep deformation under load at elevated temperature (see subsection on corrosion and environmental effects).

At a slightly larger level, linear atomic packing defects known as dislocations, give rise to the ability of metallic materials to deform substantially under load. When a plane of atoms in the lattice ends, it gives rise to an edge “dislocation” such as that shown in Figure 12.1.1a. Such a dislocation can break and remake bonds relatively easily in a metal and thereby shift an atomic distance (Figure 12.1.1b). The process can continue until a surface step results. Many dislocations moving in this fashion can give rise to significant shape change in the material at moderate stresses. The onset of such massive dislocation motion in a metal is termed *yield* and occurs at the “yield stress” or “elastic limit” (see subsection on strength and deformation). Dislocations explain why the yield stress can be as low as about 100 Pa (10 psi) in a pure, pristine, single crystal of metal. Dislocations also explain how a fine-grained polycrystalline metal containing many microstructural features which interfere with dislocation motion may have a yield stress as great as 10 gPa (1000 ksi). Dislocations interact with each other in three dimensions and multiply. Therefore, dislocation motion can cause a major increase in dislocation density and yield stress, termed *cold work*. Vacancies can rearrange these dislocation tangles, restoring the metal to a condition closer to its original state, thereby lowering the yield stress. This can occur at moderate annealing temperatures (see subsection on mechanical forming).

The interaction of deformation, alloying elements, temperature, and time can cause a wide variety of microstructures in a solid metal down to near atomic levels with mechanical (and other) properties which

can vary over a very wide range. It is possible to manipulate the properties of a single metal composition over a very wide range in the solid state — a behavior which can be used to mechanically form a particular metal and then use it in a demanding load-bearing application. The use of minor alloying additions can provide a yet wider range of properties with appropriate thermal and mechanical treatment.

## Casting

One of the important technological advantages of metals is their ability to incorporate a wide variety of secondary elements in a particular metal and thereby create alloys of the metal. Alloying can increase the strength of a metal by several orders of magnitude and permit the strength and ductility to be varied over a wide range by thermal and/or mechanical treatment, resulting in ease of mechanical forming or resistance to deformation.

Several metal phases may exist together in the solid as grains (crystals), or secondary phases may occur as smaller entities on grain (intercrystal) boundaries or within grains. Often the strengthening phase is submicroscopic and cannot be detected by optical metallography (reflection optical microscopy). The size and distribution of secondary phases is manipulated by thermomechanical (thermal and/or mechanical) treatment of the solid metal as well as the original casting procedure.

Casting methods include expendable mold casting (investment/precision, plaster mold, dry sand, and wet sand casting), permanent mold casting (ingot, permanent mold, centrifugal, and die casting), and continuous casting (direct chill and “splat” casting). These are listed in approximate order of cooling rate in Figure 12.1.2. As cooling rate increases, the grain (crystal) size tends to be smaller and the strength increases while compositional segregation decreases, providing more uniform properties. At the extremely high casting rates ( $10^5$  to  $10^6$ /sec) of continuous splat casting, it is possible to produce homogeneous metals not possible in terms of phase diagrams, and many metals have been produced in the amorphous state, yielding unusual metallic glasses. Ingot casting and continuous direct chill casting are primarily used to produce solid metal which will be extensively mechanically formed to final shape. The other casting methods are used to produce shapes near final dimensions, but to varying extents may receive extensive machining, forming, or finishing prior to use. For the latter group, grain refiners are frequently added to reduce solidification grain size. Metal tends to solidify directionally, with grains elongated in the direction of heat flow. This gives rise to directional mechanical properties which should be accounted for in design.

**Comparison of Casting Methods**

	Solidification Rate	Grain Size	Strength	Segregation
Expendable mold	Slow	Coarse	Low	Most
Investment	↓	↑	↓	↑
Plaster mold				
Dry sand				
Green sand				
Reusable mold	↓	↑	↓	↑
Ingot				
Permanent mold				
Centrifugal				
Die cast				
Continuous — direct chill				
Continuous — splat cast	Fast	Fine	High	Least

**FIGURE 12.1.2** The effects of casting speed (solidification rate) are compared.

To obtain optimum properties and prevent flaws which may cause failure, the casting procedure must avoid or control compositional segregation, shrinkage cavities, porosity, improper texture (grain directionality), residual (internal) stresses, and flux/slag inclusions. This can be accomplished with good

casting practice. With the exception of investment (lost wax, precision) casting and to a lesser extent die casting, it is difficult to achieve very exacting tolerances and fine surface finish without postfinishing or forming of a casting.

## Strength and Deformation, Fracture Toughness

Figure 12.1.3 shows a typical stress–strain diagram for a metal. The first portion is a linear, spring-type behavior, termed *elastic*, and attributable to stretching of atomic bonds. The slope of the curve is the “stiffness” (given for various metals in Table C.3 of the Appendix). The relative stiffness is low for metals as contrasted with ceramics because atomic bonding is less strong. Similarly, high-melting-point metals tend to be stiffer than those with weaker atomic bonds and lower melting behavior. The stiffness behavior is frequently given quantitatively for uniaxial loading by the simplified expressions of Hooke’s law:

$$\varepsilon_x = \sigma_x/E \quad \varepsilon_y = \varepsilon_z = -\nu\sigma_x/E \quad (12.1.1)$$

FIGURE 12.1.3 Typical engineering stress–strain curve for a metal.

Where  $\sigma_x$  is the stress (force per unit area, psi or Pa) in the  $x$  direction of applied unidirectional tensile load,  $\varepsilon_x$  is the strain (length per unit length or percent) in the same direction  $\varepsilon_y$  and  $\varepsilon_z$  are the contracting strains in the lateral directions,  $E$  is Young’s modulus (the modulus of elasticity), and  $\nu$  is Poisson’s ratio. Values of the modulus of elasticity and Poisson’s ratio are given in Table C.6A of the Appendix for pure metals and in C.6B for common engineering alloys. It may be noted that another property which depends on atomic bond strength is thermal expansion. As the elastic modulus (stiffness) increases with atomic bond strength, the coefficient of linear expansion tends to decrease, as seen in Table C.6.

The relationship of Equation (12.1.1) is for an isotropic material, but most engineering metals have some directionality of elastic properties and other structure-insensitive properties such as thermal expansion coefficient. The directionality results from directional elongation or preferred crystal orientation,

which result from both directional solidification and mechanical forming of metals. In most cases two elastic moduli and a Poisson's ratio are required to fully specify behavior. A principal modulus might be given in the rolling direction of sheet or plate with a secondary modulus in the transverse direction. A difference of 2 to 5% should ordinarily be expected, but some metals can show an elastic modulus difference as great as a factor of 2 in the principal directions of heavily formed material. Such directional differences should be accounted for when spring force or dimensional tolerance under load (or change of temperature) is critical in a design.

At a critical stress the metal begins to deform permanently, as seen as a break in the straight-line behavior in the stress-strain diagram of Figure 12.1.3. The stress for this onset is termed the yield stress or elastic limit. For engineering purposes it is usually taken at 0.2% plastic strain in order to provide a predictable, identifiable value. An extensive table of yield values and usual applications for commercial metals and alloys is given in Appendix C.5. In the case of steel a small yield drop allows for clear identification of the yield stress and this value is used. The onset of yield is a structure-sensitive property. It can vary over many orders of magnitude and depends on such factors as grain size and structure, phases present, degree of cold work, and secondary phases in grains or on grain boundaries as affected by the thermal and mechanical treatment of the alloy. The extension to failure, the ductility, and maximum in the stress-strain curve, the "ultimate stress" or "tensile strength" (see Appendix C.5) are also structure-sensitive properties. The strength and specific strength (strength-to-weight ratio) generally decrease with temperature.

The ductility usually decreases as the strength (yield or ultimate) increases for a particular metal. Reduction in the grain size of the metal will usually increase yield stress while decreasing ductility (Figure 12.1.4). Either yield or ultimate strength are used for engineering design with an appropriate safety factor, although the former may be more objective because it measures the onset of permanent deformation. Ductility after yield provides safety, in that, rather than abrupt, catastrophic failure, the metal deforms.

**FIGURE 12.1.4** The effect of grain (crystal) size on yield stress and elongation to failure (ductility) for cartridge brass (Cu-30 Zn) in tension.

A different, independent measure is needed for impact loads — "toughness." This is often treated in design, materials selection, and flaw evaluation by extending Griffith's theory of critical flaw size in a brittle material:

$$\sigma_f = K_{Ic} / \gamma c^{1/2} \quad (12.1.2)$$

where  $\sigma_f$  is the failure stress,  $K_{Ic}$  is a structure-sensitive materials property, the “fracture toughness” or “stress intensity factor” for a normal load,  $\gamma$  is a constant depending on orientation, and  $c$  is the depth of a long, narrow surface flaw or crack (or half that of an internal flaw). This is a separate design issue from that of strength. It is of particular importance when a metal shows limited ductility and catastrophic failure must be avoided. In some applications the growth of cracks,  $c$  is monitored to prevent catastrophic failure. Alternatively, as a performance test sufficient energy absorption as characteristic of a metal is determined when it is fractured in a Charpy or Izod impact test. Many metals will show a rapid decline in such energy absorption below a nil ductility temperature (NDT), which may establish a lowest use temperature for a particular metal in a particular state and for a particular application. Welds are often qualified by impact tests as well as strength testing. Care must be taken to apply the impact test appropriate to an application.

Hardness, the resistance of the near surface of a metal to penetration by an indenter, is also employed as a mechanical test. Increased hardness can often be correlated with an increase in yield and ultimate strengths. Typical hardness values for a large number of commercial metals and alloys are provided in Appendix C.5. A hardness indent is frequently done to “determine” the strength of a steel, using “equivalency” tables. Great caution must be taken in applying such tables because while hardness is an easy test to perform, it measures a complex and interactive set of properties, increasing with strength, elastic modulus, and work hardening rate. It is also an observation of surface properties which may not be characteristic of the bulk metal — particularly thick-gauge steel used in tension. Surface-hardening treatments can make the simplistic use of an “equivalency” table particularly dangerous. Application to nonferrous metals is also problematic. If a hardness tested part is to be put into service, the placement of hardness indents (surface flaws) can cause permanent failure.

A summary of important engineering metals can be found in Appendix C.5. This extensive table provides strength, hardness, and applications information for many commercial metals in varied heat treatments.

## Mechanical Forming

Hot working is used when major shape change, cross-section reduction, or texture (directional) properties are desired. Cold working is preferred when close tolerances and fine surface finish are needed. The cold-worked form of a metal typically shows higher yield and tensile strength, as can be seen for several alloys listed in Appendix C.5. Rolling, forging, and extrusion are primarily done hot, while shape drawing, extrusion, deep drawing, stretching, spinning, bending, and high-velocity forming are more commonly performed cold. Hot rolling between parallel rollers is used to reduce ingots to plates, sheets, strips, and skelp, as well as structural shapes, rail, bar, round stock (including thick-walled pipe), and wire. Sheet metal and threads on round or wire stock may be rolled to shape cold. Closed die hot forging employs dies with the final part shape, while open die forging (including swaging and roll forging) uses less-shaped dies. Coining, embossing, and hobbing are cold-forging operations used to obtain precision, detailed surface relief or dimensions. Generally, extrusion and die drawing require careful control of die configuration and forming rate and, in the latter case, lubricant system. Impact extrusion, hydrostatic extrusion, and deep drawing (thin-walled aluminum cans) permit very large precise dimensional and cross-section changes to be made cold in a single pass. Stretching, spinning, bending are usually used to shape sheet or plate metal and the spring-back of the metal due to elastic modulus must be accounted for to obtain a precise shape.

## Solute, Dispersion, and Precipitation Strengthening and Heat Treatment

Alloying additions can have profound consequences on the strength of metals. Major alloying additions can lead to multiphase materials which are stronger than single-phase materials. Such metal alloys may also give very fine grain size with further strengthening of material. Small alloying additions may also

substantially increase strength by solute strengthening as solid solution substitutional or interstitial atoms and or by particle strengthening as dispersion or precipitation hardening alloys.

Substitutional solute strengthening of copper by various atoms is shown in Figure 12.1.5. As the amount of an alloying element in solution increases, the strength increases as dislocations are held in place by the “foreign” atoms. The greater the ionic misfit (difference in size — Sn is a much larger ion than Ni), the greater the strengthening effect. The strength increase can be quite dramatic — as much as a 20-fold increase with a 1.5% addition to copper. Alternatively, a large addition of a very soluble element such as nickel can give major strengthening — monel, the Cu–70Ni alloy is more than four times stronger than pure copper (Figure 12.1.6). Interstitial solid solution carbon contributes to the strength of iron and is one contributor to strength in steels and cast irons. Solute strengthening can become ineffective in strengthening at elevated temperature relative to the absolute melting point of a metal as a result of rapid diffusion of substitutional and interstitial elements. The addition of more than one solute element can lead to synergistic strengthening effects, as this and other strengthening mechanisms can all contribute to the resistance of a metal to deformation.

**FIGURE 12.1.5** Effect of various substitutional atoms on the strength of copper. Note that as the ionic size of the substitutional atom becomes larger the strengthening effect becomes greater.

Ultrafine particles can also provide strengthening. A second phase is introduced at submicroscopic levels within each crystal grain of the metal. This may be done by a variety of phase-diagram reactions, the most common being precipitation. In this case the solid alloy is heated to a temperature at which the secondary elements used to produce fine second-phase particles dissolve in the solid metal — this is termed *solution heat treatment*. Then the metal is usually quenched (cooled rapidly) to an appropriate

**FIGURE 12.1.6** Variation in properties for copper–nickel random solid solution alloys. Note that over time at low temperature alloys (monel) may become nonrandom with significant strength increases.

temperature (e.g., room temperature or ice brine temperature) and subsequently held at an elevated temperature for a specified “aging” time during which particles precipitate and grow in size at near atomic levels throughout the solid metal. Temperature, time, alloy composition, and prior cold work affect the size and distribution of second-phase particles. The combination of treatments can be quite complex, and recently “thermomechanical treatments” combining temperature, time, and dynamic working have resulted in substantial property improvements. Heat treatment can be performed by the user, but it is difficult to achieve the optimum properties obtained by a sophisticated metallurgical mill. The heat treatment can manipulate structure and properties to obtain maximum strength or impact resistance. When metal is to be cold worked, a “softening treatment” can be employed which provides low yield

stress and high ductility. The difference between the “dead soft” and maximum strength conditions can be over an order of magnitude — a useful engineering property change.

Alternative surface diffusion methods such as nitriding and carburizing, which introduce particles for fracture and wear resistance, are presented in the subsection on metal surface treatments.

In the case of dispersion strengthening (hardening), the fine strengthening particles are a discontinuous second phase without atomic continuity with the matrix. The behavior of such particles is shown schematically in [Figure 12.1.7a](#) as a function of increasing aging time or aging temperature (fixed time) which result in larger, more widely spaced dispersed-phase particles. Under stress, dislocations must move around (bypass) such particles, so that yield strength decreases with increased aging. Long aging times may be used to decrease yield strength (“soften”) of the metal for fabrication. A short aging time, would be used for maximum strength. The dispersed phase can also provide some enhancement of ductility. A dispersion-strengthened metal for which the dispersed phase is stable at elevated temperatures can provide both high-temperature strength and creep resistance (subsection on high-temperature effects). Surface diffusion treatments usually produce dispersion hardening.

Precipitation strengthening (hardening) employs particles which have at least some atomic continuity with the matrix metal. Thus, when the metal is deformed, dislocations can either bypass or pass through (cut) the particles. The resulting behavior is shown in [Figure 12.1.7b](#). As aging time or temperature increases (particles grow larger and more widely spaced), the yield stress increases to a maximum and then decreases. The maximum is termed *critically aged*, and when this designation is part of an alloy treatment, precipitation strengthening may be assumed. For fabrication by cold working, the lower-strength, higher-ductility *underaged* condition is usually employed. There are different possible combinations of thermal and mechanical treatment which will provide a maximum critical aging treatment. Usually the best optimum for strength is given in handbooks and data sheets. However, improved treatments may be available, particularly of the combined thermomechanical type.

## Strengthening of Steels and Steel Heat Treatment

Steels, perhaps the most important of all engineering metals, are alloys of iron and carbon usually containing about 0.02 to 1.0 % carbon. The binary Fe–C phase diagram is important in describing this behavior and is shown in [Figure 12.1.8](#). This diagram shows what phases and structures will occur in quasi equilibrium at various carbon contents and temperatures (under atmospheric pressure). Steel forming and heat treatment center on the transformation from austenite,  $\gamma$  phase, at elevated temperature to ferrite ( $\alpha$  phase) plus cementite (iron carbide,  $\text{Fe}_3\text{C}$ ) below  $727^\circ\text{C}$  ( $1340^\circ\text{F}$ ), the  $A_{c1}$  temperature, a eutectoid transformation. If there are no other intentional alloying elements, the steel is a “plain carbon” steel and has an AISI (American Iron and Steel Institute) designation 1002 to 10100. The first two characters indicate that it is a plain carbon steel, while the latter characters indicate the “points” of carbon.\* Alloy steels, containing intentional alloying additions, also indicate the points of carbon by the last digits and together with the first digits provide a unique designation of alloy content. In the phase diagram ([Figure 12.1.8](#)) iron carbide ( $\text{Fe}_3\text{C}$ , cementite) is shown as the phase on the right. This is for all practical purposes correct, but the true thermodynamically stable phase is graphite (C) — relevant when the eutectic at  $1148^\circ\text{C}$  ( $2048^\circ\text{F}$ ) is used to produce cast irons (alloys greater than 2 % C).

The solid-state eutectoid transformation is promoted by the magnetic effect in iron as nonmagnetic austenite transforms below the eutectoid ( $A_{c1}$ ) temperature to the two magnetic solid phases ferrite (iron with solid solution carbon) and cementite solid phase.\*\* At the eutectoid composition, 0.77 % carbon,

\* Plain carbon steels contain about 0.2 % Si, 0.5 % Mn, 0.02 % P, and 0.02 % S.

\*\* It should be noted that austenitic stainless steels (300 and precipitation hardening, PH, series designations), nonmagnetic alloys with considerable chromium and nickel content to provide corrosion resistance, do not ordinarily transform from austenite to the lower-temperature phases. They are not intentionally alloyed with carbon, are not magnetic, and do not show the phase transformation strengthening mechanisms of steels. The term *steel* is something of a misnomer for these alloys.

**FIGURE 12.1.7** Effect of aging on dispersion- and precipitation-strengthened alloys for a fixed second-phase addition. (a) Dispersion strengthening: as aging time or temperature increases (dispersed phase particles larger and more separated), yield strength increases. A lower bound exists for near atomic size particles. (b) Precipitation hardening: two behaviors can occur giving a composite curve with a maximum at the critical aging time or temperature (optimum size and spacing of particles).

the two phases form as a fine alternating set of plates (lamellae) termed *pearlite* because of their pearlike appearance in a metallographic microscope. This two-phase structure of metal (ferrite) and carbide (cementite) provides strength (very slowly cooled — about 65 ksi, 14% tensile elongation), which increases as a more-rapid quenching yields a finer pearlite microstructure (to about 120 ksi). As strength increases, ductility and fracture toughness decrease. With yet more rapid quenching and more local atomic diffusion, the austenite transforms to bainite, a phase of alternating carbon and iron-rich atomic planes. This has yet higher strength (to about 140 ksi) and lower ductility. When the metal is quenched so rapidly that carbon diffusion is prevented, the austenite becomes unstable. Below a critical temperature,

**FIGURE 12.1.8** Iron–carbon phase diagram relevant for steel. The steel composition range is from about 0.02 to 1.00 % carbon. Steel strengthening treatments require heating into the austenite region (above the  $A_{c3}$ ) and then quenching.

the martensitic start temperature ( $M_s$ ), the metal transforms spontaneously by shear to martensite. Full transformation occurs below the martensite finish temperature ( $M_f$ ). The formation of this hard phase introduces enormous microscopic deformation and residual stress. The strength is very much higher (about 300 ksi) but there is almost no ductility. This rapidly cooled material can spontaneously fail from “quench cracking,” which results from residual stresses and the martensite acting as an internal flaw. To relieve stresses and provide some fracture toughness, martensitic steel is “tempered” at an intermediate temperature such as 500°C for about an hour to provide some ductility (about 7%) while sacrificing some strength (about 140 ksi). Tempering for shorter times or at lower temperatures can give intermediate properties. High-carbon steels are often used for cutting tools and forming dies because of their surface hardness and wear resistance. When a high-carbon steel (>0.7 % C) requires fabrication at lower temperature, it may be held at a temperature just under the eutectoid for an extended time (e.g., for 1080 steel: 700°C, 1300°F — 100 hr) either after or without quenching to provide a soft condition (<60 ksi, 20% extension). A variety of different quenching temperatures, media, and procedures can be used to vary required combinations of the microstructures above and mechanical properties. The discussion above centered on eutectoid steel and holds for other high-carbon steels. Increasing carbon content favors the formation of martensite in steels, thereby providing increased strength, hardness, and wear resistance. However, such steels can be quite brittle.

At lower carbon content, “primary ferrite” forms (Figure 12.1.8) as the steel is quenched from above the boundary of austenitic ( $\gamma$ ) region, the  $A_{c3}$ . Subsequently, pearlite (ferrite and cementite), bainite, and/or martensite can form. Lower carbon content increases the amount of primary ferrite, a weaker/ductile phase, and decreases the tendency to form martensite, a stronger/brittle phase. The result is a more fracture tough, ductile (“safer”) steel, but strength is lower. Such steels are also mechanically more forgiving if welded. Thus, a 1010 steel (0.10 % C) might be used for applications where extreme “formability” and “weldability” are required, such as for car bodies and cans, while a 1020 steel (0.20 % C) might be used for construction materials for which some increased strength is desired while

maintaining safety. A medium-carbon steel such as a 1040 would be used when a balance of strength and toughness (and ease of welding) is needed.

In order to quench (and temper) steels continuous cooling transformation (CCT) diagrams are used such as that in [Figure 12.1.9](#) for a 1040, medium-carbon steel. The steel is quenched from above the  $A_{c3}$ . Vertical lines indicate quenching rates as shown in the lower left inset of the diagram. The cooling rate for the center of a round bar of given diameter quenched in air, oil, and water is given below the diagram. Solid lines on the diagram indicate percent transformation (start, 10%, 50%, 90%, finish of transformation), and a dotted line separates the region where primary ferrite forms from that of transformation to pearlite. The lower diagram shows the indentation hardness to be expected, as this and other mechanical behavior can be predicted from the CCT curve. As an example, the center of a 15 mm ( $\sim 1/2$  in.) diameter bar quenched in air would be about 25% primary ferrite and 75% fine pearlite, with a Rockwell C hardness (HRC) of about 15. If quenched in oil, the bar center would be chiefly bainite with a small amount of martensite ( $HRC \cong 25$ ). The same bar quenched in water would be all martensite ( $HRC \cong 55$ ) before tempering. The transformation at other positions in the bar and for other engineering shapes (sheet, pipe, square rod, etc.) can be obtained from conversion curves.

It should be noted that layers in the steel closer to the quenched surface cool more quickly and are therefore displaced toward the left of the CCT diagram. There is a variation in structure and mechanical properties from the quenched surface to the center. One result is that the surface of the steel tends to be stronger, harder, and more wear resistant than the center. A steel beam undergoing bending has maximum strength at the near surface which undergoes the greatest stresses, while the center provides safety because of its relative fracture toughness and ductility. A thin knife edge cools quickly and can be resistant to deformation and wear, while the thick back prevents the blade from snapping in half when bent.

Many elements may be incorporated in steels to promote specific properties. Almost all common additions (other than cobalt) tend to promote strengthening by the formation of martensite (or bainite) instead of pearlite. When alloying additions tend to promote martensite throughout a thick section independent of cooling rate, the alloy is said to have *high hardenability*. Some elements such as chromium, molybdenum, and nickel also may help to provide high-temperature strength and environmental resistance. One class of alloys with relatively small alloying additions are termed *HSLA* steels (high strength, low alloy) and usually show somewhat superior mechanical properties to their plain carbon steel equivalents. As steel is alloyed, the relative cost increases substantially. A useful strategy in steel selection (and steels are usually the first engineering candidate on a cost basis) is to start by determining if a medium-carbon steel will do. If greater safety and formability are needed, a lower carbon content may be used (with slightly lower cost); alternatively, a higher-carbon steel would be chosen for greater strength and wear resistance. Heat treatment would be used to manipulate the properties. If plain carbon steels prove unsatisfactory, the HSLA steels would be the next candidate. For very demanding applications, environments, and long-term operations, specialty alloy steels would be selected insofar as they are cost-effective.

## Fatigue

Fatigue is the repeated loading and unloading of metal due to direct load variation, eccentricity in a rotating shaft, or differential thermal expansion of a structure. Even substantially below the yield point (elastic limit) of a metal or alloy this repeated loading can lead to failure, usually measured in terms of the number of cycles (repeated load applications) to failure. Some studies have suggested that well over 80% of all mechanical failures of metal are attributable to fatigue.

High-stress, low-cycle fatigue usually occurs at stresses above the yield point and lifetimes are tens or hundreds of cycles (to about a thousand cycles). Failure occurs as a result of the accumulation of plastic deformation, that is, the area (energy) under the stress–strain curve ([Figure 12.1.3](#)). A simple lifetime predictive equation can be used to predict lifetime:

**FIGURE 12.1.9** CCT diagram for 1040 steel. A 15-mm round bar air quenched from above the  $Ac_3$  will be chiefly fine pearlite (ferrite and iron carbide, cementite) with about a quarter of the structure primary ferrite at the center. Quenching in oil will yield bainite with about 10% martensite. Water quenching will produce wholly martensite at the center. (After Atkins, M., *Atlas of Continuous Cooling Transformation Diagrams for Engineering Steels*, ASM International, Materials Park, OH, 1980.)

$$N \approx \left[ \epsilon_u / 2\epsilon_{pf} \right]^2 \quad (12.1.3)$$

where  $N$  is the number of cycles to failure,  $\epsilon_u$  is total strain from the stress–strain curve, and  $\epsilon_{pf}$  is the plastic strain amplitude in each fatigue cycle.

More commonly, metals are used well below their yield point and fail after many, many cycles of repeated loading in low-stress, high-cycle fatigue. There is microscopic, local plastic deformation (cold working) and vacancy generation (recovery effects) during such cyclic loading which result in “fatigue hardening” (strengthening) of unworked metal and “fatigue softening” of unworked metal. Some have even found success relieving residual stressed with a vibratory anneal. Early in the fatigue process surface flaws or in some cases severe internal flaws begin to propagate. The fatigue crack propagates in areas of high stress a small, usually submicroscopic, distance with each tensile loading. The propagation on each cycle frequently leaves identifiable marking on the failure surface termed *fatigue striations* which mark the progress of the subcritical crack. When the crack becomes so large that the fracture toughness criterion is exceeded (Equation 12.1.2), catastrophic overload failure occurs. When the future fatigue loading can be predicted and the cyclic crack propagation rate is known, fatigue cracks can be inspected or monitored in different applications such as aircraft structures and pressure vessels to decommission or replace parts before fatigue failure. This must be done cautiously because a change to a more aggressive (corrosive, oxidative, elevated temperature) environment can increase the crack propagation rate. If a harmonic resonance occurs in the metal part, vibratory maxima can cause premature fatigue failure. Harmonics can change as fatigue cracks propagate. Harmonic vibration can be prevented with vibratory (dynamic) design concepts and/or direct monitoring.

Figure 12.1.10 shows typical metal  $S$ – $N$  curves (stress vs. number of cycles to failure) for a high-strength aluminum and for a titanium alloy. Note that the convention is to make stress the vertical axis and to plot the number of cycles to failure on a logarithmic scale. For high-stress, low-cycle fatigue ( $<10^3$  cycles) the curve is flat and linear, consistent with the model of Equation 12.1.3. For high cycle fatigue the lifetime is a rapidly varying function of stress until very low stresses (long lifetimes occur). The actual fatigue life varies statistically about the mean value shown in approximate proportion to the number of cycles to failure. These curves are for testing in ambient air. Fatigue life would be longer in an inert environment and may be shortened drastically in an aggressive environment. Iron- and titanium-based alloys, such as the example shown, usually have an “endurance limit,” a stress below which lifetime is ostensibly infinite. In air, at room temperature, the endurance limit is about half the tensile strength for most iron and titanium alloys. Other metals appear to show no stress below which they last indefinitely. Therefore, a “fatigue limit” is designated — usually the stress at which the fatigue life is  $10^8$  cycles. This may be a long lifetime or not depending on the frequency of loading and engineering lifetime. The fatigue limit is generally about 0.3 times the tensile strength for metals with strengths below about 100 ksi (700 MPa). The factor is somewhat poorer for higher-strength metals. It is apparent that on a relative strength basis, iron- and titanium-based alloys are fatigue-resistant metals when compared with others. Dispersion-strengthened alloys have been seen to provide some lifetime advantage in fatigue.

A number of mathematical relationships have been proposed to predict fatigue life, but none works with complete success and all require experimental data. Perhaps the most successful of the so-called fatigue “laws” are the “cumulative damage” laws. The simplest is Miner’s law:

$$\sum i \left[ n_i / N_i \right] = 1 \quad (12.1.4)$$

where  $n_i$  is the number of cycles applied and  $N_i$  is the number of cycles for failure at a particular stress level,  $\sigma_i$ . The conceptual basis is that the number of fatigue cycles at a stress level uses up its relative fraction of total fatigue lifetime and may be correlated to fatigue crack propagation (striation spacing). Modifications of this model account for the order and relative magnitude of loads. Several techniques

**FIGURE 12.1.10**  $S$ - $N$  (fatigue) curves for high-strength titanium (upper curve) and aluminum alloys. Note that titanium (and iron) alloys show an endurance limit, a stress below which the metal lasts indefinitely.

have met with partial success in increasing fatigue lifetime beyond that predicted by the cumulative damage models:

1. Coaxing — intermittent or continuous, superimposed vibration at very low stress,
2. Overstressing — intermittent or superimposed compressive loading,
3. Surface compression — intermittent shot peening or surface rolling,
4. Surface removal — chemical or mechanical surface polishing.

All but 1 are thought to close or eliminate fatigue cracks and surface damage. Coaxing has been said to introduce more of the vacancy-related recovery effects associated with fatigue.

### High-Temperature Effects — Creep and Stress Rupture

Elevated temperature can cause a significant loss of strength and elastic modulus, so that a metal part may fail as a result of overheating even at loads which appear small at room temperature. High temperature is a relative matter and is usually judged as a fraction of the melting point measured on the absolute temperature scale. Thus, even moderate temperature excursions can be important for low-melting-point metals and alloys. As indicated in several sections above, many alloying and cold work strengthening methods depend upon heat treatment; an alloy can undergo metallurgical change due to overheating or to long-term holds at moderate temperatures and thereby alter properties significantly. Thus, the thermal stability of the microstructure should be determined. For example, metallographic replica techniques have been developed for determining in the field if microstructure has coarsened, making the metal weak.

Creep deformation is the continued deformation of a metal under load at elevated temperature, usually at a design stress well below the yield point. While measurable creep can occur at low temperatures over very long times or at very high (compressive) loads, creep usually becomes of engineering importance above about two thirds the melting point (absolute) of an alloy. Thus, both lead, which creeps at room temperature, and tungsten, which creeps in an incandescent light bulb at white heat, require a mechanical support or creep-resistant alloying additions. Figure 12.1.11 shows a schematic creep curve plotting creep strain\* vs. time,  $t$ , at a particular tensile load and temperature. After the immediate elastic

\* If a constant extension is applied to an object, the force it generates will decline over time due to creep. This is called *stress relaxation* and can be treated in a similar way.

**FIGURE 12.1.11** Schematic creep curve showing transient creep (I), steady-state creep (II), and tertiary creep (III). Note that the slope of the straight-line portion is the steady-state creep rate (minimum creep rate).

strain ( $t = 0$ ), “transient creep” occurs in Region I. At elevated temperature this usually follows a  $t^{1/3}$  behavior (Andrade creep). The majority of the curve has a straight-line behavior (Region II) in which the extension with time is constant. The slope of this part of the curve is termed the *steady-state strain rate* or *minimum creep rate*. It is used to calculate the creep extension which could cause functional failure when dimensional tolerances are exceeded. A simplified predictive model is

$$\dot{\epsilon}' = A\sigma^m e^{-h/kT} \quad (12.1.5)$$

where  $\dot{\epsilon}'$  is the minimum creep rate,  $A$  is a constant,  $\sigma$  is the applied stress,  $m$  is the stress dependence exponent (often 4 to 8),  $h$  is the activation enthalpy for creep, and  $T$  the absolute temperature.

In Region III the creep rate accelerates as the metal necks down severely in a local area, thereby increasing the local stress. The steady-state rate would continue (dotted line) if the load were adjusted to give constant load at the minimum cross section. Since loads do not readjust to compensate for necking in real applications, a final accelerated stage can be experienced. For example, a blowout can occur in late creep of a pressurized high-temperature piping system. The time to failure is termed the *stress rupture lifetime*. Predictive models are developed from Equation (12.1.5) to provide lifetime information.

Lowering use temperature or applied stress decreases susceptibility to creep deformation and increases stress rupture lifetime. Frequently, a moderate temperature decrease is most effective in this regard. Higher-melting-point metals are more creep resistant, so that the refractory metals tungsten and molybdenum can be used but require an inert atmosphere or protective coating to prevent rapid oxidation. In air or other active atmosphere, niobium-, nickel-, titanium-, and iron-based alloys may be used for creep resistance. Dispersion hardening, particularly with a high-temperature stable phase, such as an oxide, nitride, or carbide, can confer a degree of creep resistance.

## Corrosion and Environmental Effects

Corrosion usually involves the slow removal of metal due to chemical and/or electrochemical reaction with an environment. Most metallic corrosion involves a galvanic, that is, electrochemical, component and localized attack in the form of pitting, attack in crevices, grain boundary attack, selective leaching

of one phase, and exfoliation (attack parallel to the surface causing layers to peel away). Uniform corrosion is less common and also less of a concern as long as the rate of material removal is gradual and predictable.

Galvanic corrosion requires a medium, usually liquid (water), often containing a specific agent which promotes corrosion, a potential difference, and a complete electrical circuit, as well as an anode and a cathode. The anode will be the attacked, corroded, portion of the system. One cause for potential corrosion is dissimilar metals. For example, the galvanic series in seawater shows magnesium alloys as most anodic followed by zinc, aluminum, iron, nickel, brass, and copper alloys which are progressively more cathodic. When coupled electrically, the more-anodic metal would be corroded and the more cathodic would promote corrosion. One way of preventing corrosion is to isolate with insulator material the metal parts electrically so that a circuit is interrupted. The surfaces can be isolated from the corroding medium with paint, protective metal, conversion coatings, or a corrosion inhibitor additive to the liquid. In this situation it is more important to coat the cathode (noncorroding metal) since it impresses corrosion on the anodic metal dependent on exposed area. When in doubt, all parts should be painted repeatedly to prevent pinholes. Other possibilities include cathodic protection with an impressed electrical counterpotential or use of a sacrificial anode which is attacked instead of the metal components. Some metals such as stainless steels and aluminum alloys provide protection via an oxide coating, a *passive film*, which will form under specific, controlled electrochemical conditions providing *anodic protection*.

Another source for an anode and cathode can be the solution itself. Differences in temperature, ion concentration, oxygen content, and pH can all lead to a potential difference which results in corrosion. Often corrosion occurs far more rapidly for a specific range of solution concentration — indeed, sometimes dilution may accelerate corrosive attack. An oxygen deficiency cell under dirt or in a crevice frequently causes attack at the resulting anode. Potential differences can also exist in the metal itself: between different phases, inclusions, or grain chemistries; between grains and grain boundaries; between surface films and metal; and between different grain orientations. Selective leaching such as dezincification of high-zinc brasses (Cu–Zn) is an example for composition differences, while exfoliation corrosion of aluminum alloys and sensitized stainless steel are examples of grain boundary attack. Cold-worked metal tends to be anodic to annealed material so that a heavily formed part of a metal part may corrode preferentially.

Another important environmental cause of failure is stress corrosion cracking (SCC). A combination of applied or residual tensile stress and environmental attack results in progressive slow crack propagation over a period of time. Eventually, the crack becomes critical in size (Equation 12.1.2) and catastrophic failure occurs. There need be no evidence of corrosion for SCC to occur. When the loading is of a cyclic nature the effect is termed *corrosion fatigue*. To prevent these long-term crack propagation effects the environment and/or the source of tensile load may be removed. Considerable effort has been made to identify an ion concentration below which stress corrosion cracking will not occur (e.g., Cl for austenitic stainless steels), but there may be no level for complete immunity, merely a practical maximum permissible level.

Hydrogen embrittlement and hydrogen cracking can occur in the presence of stress and a hydrogen source. Embrittlement results when hydrogen diffuses into the metal and/or acts on the crack tip altering the fracture toughness. Hydrogen cracking may be regarded as a special case of stress corrosion cracking. Either environmental effect can lead to catastrophic failure. The source of hydrogen can be an acid solution, hydrogen evolved during corrosion, electrochemical treatment (plating, electropolishing), or hydrocarbons. Often isolation from the hydrogen source is difficult because hydrogen diffuses quickly through most materials and barrier coatings. Glass coating has met with some success.

## Metal Surface Treatments

A number of treatments are employed to strengthen the surface of steels and make them more resistant to failure or wear. Some of the techniques may also be applied to selected nonferrous alloys. Flame, induction, and laser hardening provide intense heat to the outer surface of a medium- or high-carbon

(hardenable) steel bringing it into the austenitic region, above  $A_{c_3}$  (see subsection on fatigue). The bulk of the metal is not heated so that the surface can then be quenched rapidly forming hardening phases and a compressive surface stress. This provides strength and wear resistance. Another surface-hardening technique is carburizing. This can also be used on steels with lower carbon content. The metal is exposed to a controlled balance of carbon monoxide and carbon dioxide or is packed in graphite. At elevated temperature (usually above the  $A_{c_3}$ ) carbon diffuses into the surface, converting it to a high-carbon steel. The steel is then either quenched directly from the carburizing temperature or re-austenitized and quenched. The result is similar to flame hardening, but higher hardness and surface compression can be accomplished compared with flame hardening. The center of the piece, with much lower carbon content, can provide fracture toughness, ductility, and safety. Nitriding exposes steel containing appropriate alloying elements (chromium, aluminum, vanadium, ...) to monatomic nitrogen in the form of cracked ammonia, cyanide, or high-energy dissociated nitrogen gas. This is done below the eutectoid (lower transformation) temperature. Dispersed-phase nitrides are formed as nitrogen diffuses into the surface which harden the surface without a need for further heat treatment. The effects of both carburizing and nitriding can be introduced by carbonitriding above the transformation temperature and quenching or nitrocarburizing below the transformation to austenite.

## 12.2 Polymers

---

*James D. Idol and Richard L. Lehman*

### Introduction

Polymers constitute a wide range of materials which are derived at least in part from organic, usually petroleum-based, raw materials; they consist of repeating molecular units and have special properties obtained by engineering the form of the molecular structures. The term *polymer* is derived from Greek roots and means “having many parts,” a term which aptly describes the infinite number of compounds which can be synthesized from a relatively limited number of monomer units. The term *plastic* is often used in describing polymers, although this term is not in current usage since it is a general descriptive which refers to the forming rheology of many polymers but is too general to accurately describe this group of materials.

Polymers are used as engineering materials in the neat form, i.e., as the pure material, or in combination with a large diversity of additives, both organic and inorganic. These additives may be, among others, plasticizers which reduce the rigidity or brittleness of the material, fillers which increase strength and load deflection behavior under load, or stabilizers which protect the polymer against ultraviolet radiation.

The following discussion will separate polymers into two groups, thermoplastic and thermosetting, based on the distinctly different thermal processing behavior of these two broad classes of polymers. Thermoplastic polymers soften when heated and can be reshaped, the new shape being retained on cooling. The process can be repeated many times by alternate heating and cooling with minimal degradation of the polymer structure. Thermosetting polymers (or thermosets) cannot be softened and reshaped by heating. They are plastic and moldable at some state of processing, but finally set to a rigid solid and cannot be resoftened. Thermosets are generally stronger and stiffer than thermoplastic.

Table 12.2.1 of this section gives an overview of the physical properties of the most commonly used industrial polymers. Table 12.2.2 provides an overview of properties such as chemical resistance, ease of machining, and compressive strength for thermoplastic and thermosetting plastics, while Table 12.2.3 is a selection guide for polymers by application. A detailed summary of polymer properties, including electrical properties, thermal properties, optical properties, and fabrication, is presented in Table 12.2.4.

### Thermoplastic Polymers

#### Acetal and Polyacetal

These combine very high strength, good temperature and abrasion resistance, exceptional dimensional stability, and low coefficient of thermal expansion. They compete with nylon (but with many better properties) and with metal die castings (but are lighter). Chemical resistance is good except for strong acids. Typical applications are water-pump parts, pipe fittings, washing machines, car instrument housings, bearings, and gears.

#### Acrylics (Methylmethacrylate, PMMA)

These are noted for their optical clarity and are available as sheet, rod, tubings, etc., as Perspex (U.K.) and Plexiglas (U.S., Germany, etc.). They are hard and brittle and quite resistant to discoloring and, especially, weathering. Applications include outdoor display signs, optical lenses and prisms, transparent coverings, drafting instruments, reflectors, control knobs, baths, and washbasins. They are available in a wide range of transparent and opaque colors.

#### Acrylonitrile-Butadiene-Styrene (ABS)

This combination of three monomers gives a family of materials which are strong, stiff, and abrasion resistant with notable impact-resistance properties and ease of processing. The many applications include

Note: O = outstanding, E = excellent, G = good, F = fair, P = poor.

<sup>a</sup> Tensile strength (typical): E = 55  $\text{Nmm}^{-2}$ ; P = 21  $\text{Nmm}^{-2}$ .

<sup>b</sup> Compressive strength (typical): E = 210  $\text{Nmm}^{-2}$ ; P =  $\text{Nmm}^{-2}$ .

pipes, refrigerator liners, car-instrument surrounds, radiator grills, telephones, boat shells, and radio and television parts. Available in medium, high, and very high impact grades.

## Cellulosics

“Cellulose nitrate” is inflammable and has poor performance in heat and sunlight. Its uses are therefore limited. Cellulose acetate has good strength, stiffness, and hardness and can be made self-extinguishing. Glass-filled grades are made. Cellulose acetate-butyrate (CAB) has superior impact strength, dimensional stability, and service temperature range and can be weather stabilized. Cellulose propionate (CP) is similar to CAB, but has better dimensional stability and can have higher strength and stiffness. Ethyl cellulose has better low-temperature strength and lower density than the others. Processing of cellulose

**TABLE 12.2.3 Selection Guide for Polymers by Application**

Application or Service	Properties Required	Suitable Plastics
Chemical and thermal equipment	Resistance to temperature extremes and to wide range of chemicals; minimum moisture absorption; fair to good strength	Fluorocarbons, chlorinated polyether, polyvinylidene fluoride, polypropylene, high-density polyethylene, and epoxy glass
Heavily stressed mechanical components	High-tensile plus high-impact strength; good fatigue resistance and stability at elevated temperatures; machinable or moldable to close tolerance	Nylons, TFE-filled acetals, polycarbonates, and fabric-filled phenolics
Electrostructural parts	Excellent electrical resistance in low to medium frequencies; high-strength and -impact properties; good fatigue and heat resistance; good dimensional stability at elevated temperatures	Allylics, alkyds, aminos, epoxies, phenolics, polycarbonates, polyesters, polyphenylene oxides, and silicones
Low-friction applications	Low coefficient of friction, even when nonlubricated; high resistance to abrasion, fair to good form stability and heat and corrosion resistance	Fluorocarbons (TFE and FEP), filled fluorocarbons (TFE), TFE fabrics, nylons, acetals, TFE-filled acetals, and high-density polyethylenes
Light-transmission components, glazing	Good light transmission in transparent or translucent colors; good to excellent formability and moldability; shatter resistance; fair to good tensile strength	Acrylics, polystyrenes, cellulose acetates, cellulose butyrates, ionomers, rigid vinyls, polycarbonates, and medium-impact styrenes
Housings, containers, ducts	Good to excellent impact strength and stiffness; good formability and moldability; moderate cost; good environmental resistance; fair to good tensile strength and dimensional stability	ABS, high-impact styrene, polypropylene, high-density polyethylene, cellulose acetate butyrate, modified acrylics, polyester-glass and epoxy-glass combinations

plastics is by injection molding and vacuum forming. Applications include all types of moldings, electrical insulation, and toys.

### Ethylene-Vinyl Acetate (EVA)

This material gives tough flexible moldings and extrusions suitable for a wide temperature range. The material may be stiffened by the use of fillers and is also specially formulated for adhesives. Applications include all types of moldings, disposable liners, shower curtains, gloves, inflatables, gaskets, and medical tubing. The material is competitive with polyvinyl chloride (PVC), polyethene, and synthetic rubbers, and is also used for adhesives and wax blends.

### Fluorocarbons

This class of polymers, characterized by fluorine substitution, has outstanding chemical, thermal, and electrical properties and is characterized by the following four main classes of structures.

Polytetrafluoroethylene (PTFE), known commercially as Teflon or Fluon, is the best-known material and resists all known chemicals, weather, and heat, has an extremely low coefficient of friction, and is “non-stick.” These materials are inert with good electrical properties. They are nontoxic, nonflammable, and have a working temperature range of  $-270$  to  $260^{\circ}\text{C}$ . They may be glass filled for increased strength and rigidity. They do not melt and they must be formed by sintering of powders. Applications include chemical, mechanical, and electrical components, bearings (plain or filled with glass and/or bronze), tubing, and vessels for “aggressive” chemicals.

Fluoroethylenepropylene (FEP), unlike PTFE, can be processed on conventional molding machines and extruded, but thermal and chemical resistance properties are not quite as good.

Ethylenetetrafluoroethylene (ETFE) possess properties similar to but not as good as those of PTFE. However, the material exhibits a thermoplastic character similar to that of polyethylene which gives it a very desirable molding behavior.

Perfluoroalkoxy (PFA) is the fourth group of fluorinated polymers. These materials have the same excellent properties as PTFE, but the compound is melt processible and, therefore, suitable for linings for pumps, valves, pipes, and pipe fittings.

### **Ionomers**

These thermoplastics are based on ethylene and have high melt strength, which makes them suitable for deep forming, blowing, and other similar forming processes. They are used for packaging, bottles, moldings for small components, tool handles, and trim. They have a high acceptance of fillers.

### **Polymethylpentene**

Polymethylpentene (TPX) is a high-clarity resin with excellent chemical and electrical properties and the lowest density of all thermoplastics. It has the best resistance of all transparent plastics to distortion at high temperature — it compares well with acrylic for optical use, but has only 70% of its density. It is used for light covers, medical and chemical ware, high-frequency electrical insulation, cables, microwave oven parts, and radar components. It can withstand soft soldering temperatures.

### **Polyethylene Terephthalate**

Polyethylene terephthalate (PETP) and modified versions thereof have high strength, rigidity, chemical and abrasion resistance, impact resistance in oriented form, and a low coefficient of friction. It is attacked by acetic acid and concentrated nitric and sulfuric acids. It is used for bearings, tire reinforcement, bottles, automotive parts, gears, and cams.

### **Polyamides (Nylons)**

The polyamides are a family of thermoplastics, e.g., Nylon 6, Nylon 66, and Nylon 610, which are among the toughest engineering plastics with high vibration-damping capacity, abrasion resistance, inherent lubricity, and high load capacity for high-speed bearings. They have a low coefficient of friction and good flexibility. Pigment-stabilized types are not affected by ultraviolet radiation and chemical resistance is good. Unfilled nylon is prone to swelling due to moisture absorption. Nylon bearings may be filled with powdered molybdenum disulfide or graphite. Applications include bearings, electrical insulators, gears, wheels, screw fasteners, cams, latches, fuel lines, and rotary seals.

### **Polyethylene**

Low-density polyethylene (originally called *polythene*) is used for films, coatings, pipes, domestic moldings, cable sheathing, and electrical insulation. High-density polyethylene is used for larger moldings and is available in the form of sheet, tube, etc. Polyethylene is limited as an engineering material because of its low strength and hardness. It is attacked by many oxidizing chemical agents and some hydrocarbon solvents.

### **Polyketone, Aliphatic**

Aliphatic polyketones are relatively strong, tough, ductile polymeric resins derived from equal proportions of ethylene and carbon monoxide with an additional few percent of higher olefin for property and processibility adjustment. Their physical, thermal, and mechanical properties are similar to polyamides and polyacetals. Mechanical properties are characterized by preservation of high levels of stiffness, toughness, and strength over a broad temperature range. Resistance to hydrolysis, swelling, and permeation provides broad chemical resistance. Relatively new in commercial supply, they find application in gears, machine components, and similar engineering applications. Tribological performance is very good, and in particular they have a low coefficient of friction and a low wear factor against steel. The electrical properties of the neat polyketone are typical of those of polar, semicrystalline thermoplastics.

### **Polyethersulfone**

Polyethersulfone is a high-temperature engineering plastic — useful up to 180°C in general and some grades have continuous operating ratings as high as 200°C. It is resistant to most chemicals and may

be extruded or injection molded to close tolerances. The properties are similar to those of nylons. Applications are as a replacement for glass for medical needs and food handling, circuit boards, general electrical components, and car parts requiring good mechanical properties and dimensional stability.

### **Polystyrene**

This polymer is not very useful as an engineering material because of brittleness in unmodified forms, but it is well known for its use in toys, electrical insulation, refrigerator linings, packaging, and numerous commercial articles. It is available in unmodified form as a clear transparent resin and also in clear and opaque colors. High-impact forms are achieved by compounding with butadiene or other rubbery resins and heat-resistant forms are achieved by the use of fillers. Polystyrene can be stabilized against ultraviolet radiation and also can be made in expanded form for thermal insulation and filler products. It is attacked by many chemicals, notably aromatic hydrocarbon solvents, and by ultraviolet light.

### **Polysulfone**

Polysulfone has properties similar to nylon, but these properties are retained up to 180°C compared with 120°C for nylon, which greatly expands the range of applications. Its optical clarity is good and its moisture absorption lower than that of nylon. Applications are as a replacement for glass for medical needs and chemistry equipment, circuit boards, and many electrical components.

### **Polyvinyl Chloride**

This is one of the most widely used of all plastics. With the resin mixed with stabilizers, lubricants, fillers, pigments, and plasticizers, a wide range of properties is possible from flexible to hard types, in transparent, opaque, and colored forms. It is tough, strong, with good resistance to chemicals, good low-temperature characteristics and flame-retardant properties. PVC does not retain good mechanical performance above 80°C. It is used for electrical conduit and trunking, junction boxes, rainwater pipes and gutters, decorative profile extrusions, tanks, guards, ducts, etc.

### **Polycarbonate**

Polycarbonate is an extremely tough thermoplastic with outstanding strength, dimensional stability, and electrical properties, high heat distortion temperature and low-temperature resistance (down to -100°C). It is available in transparent optical, translucent, and opaque grades (many colors). Polycarbonates have only fair resistance to chemicals as evidenced by the stress cracking caused by many solvents. The weathering tendencies can be stabilized against ultraviolet radiation by the use of proper additives. Polycarbonate compounds are used for injection moldings and extrusions for glazing panels, helmets, face shields, dashboards, window cranks, and gears. Polycarbonate is an important engineering plastic.

### **Polypropylene**

Polypropylene is a low-density, hard, stiff, creep-resistant plastic with good resistance to chemicals, good wear resistance, low water absorption, and is relatively low cost. Polypropylene can be spun into filaments, converted into weaves, injection molded, and is commonly produced in a large variety of forms. Glass-filled polypropylene is widely used for its enhanced mechanical properties. It is used for food and chemical containers, domestic appliances, furniture, car parts, twine, toys, tubing, cable sheath, and bristles.

### **Polyphenylene Sulfide**

Polyphenylene sulfide is a high-temperature plastic useful up to 260°C. Ambient temperature properties are similar or superior to those of nylon. It has good chemical resistance and is suitable for structural components subject to heat. Glass filler improves strength and enables very high heat resistance to 300°C. Uses are similar to those of nylon, but for higher temperatures.

## **Polyphenylene Oxide**

This is a rigid engineering plastic similar to polysulfone in uses. It can be injection molded and has mechanical properties similar to those for nylon. It is used for automotive parts, domestic appliances, and parts requiring good dimensional stability. Frequently, the commercially available product is blended (or “alloyed”) with polystyrene which acts as a cost-effective extender.

## **Thermosetting Polymers**

### **Alkyds**

There are two main groups of alkyds: diallyphthalate (DAP) and diallylisophthalate (DIAP). These have good dimensional stability and heat resistance (service temperature 170°C; intermittent use 260°C), excellent electrical properties, good resistance to oils, fats, and most solvents, but limited resistance to strong acids and alkalis. The mechanical properties are improved by filling with glass or minerals. The main uses are for electrical components and encapsulation. A wide range of colors and fast-curing grades are available.

### **Amino Resins**

These are based on formaldehyde reacted with urea or melamine and are formulated as coatings and adhesives for laminates, impregnated paper textiles, and molding powders. The resins are usually compounded with fillers of cellulose, wood flour, and/or other extenders. As composites with open-weave fabric, they are used for building panels. Uses also include domestic electrical appliances and electric light fittings; the melamine type is used for tableware. The strength is high enough for use in stressed components, but the material is brittle. Electrical, thermal, and self-extinguishing properties are good.

### **Epoxies**

Epoxy resins are used extensively across industry as engineering polymers and as adhesives. They can be cold cured without pressure using a “hardener” or may be heat cured. Inert fillers, plasticizers, flexibilizers, and extenders give a wide range of properties from soft flexible to rigid solid materials. Bonding to nearly all materials, e.g., wood, metal, glass, is excellent as are the mechanical, electrical, and chemical properties. Epoxies are used in all branches of engineering, including large castings, electrical parts, circuit boards, potting, glass and carbon fiber structures, flooring, protective coatings, and adhesives. Importantly, they exhibit little or no shrinkage on cure.

### **Phenolics (Phenol Formaldehyde, PF)**

PF, the original “Bakelite,” is usually filled with 50 to 70% wood flour for molded nonstressed or lightly stressed parts. Other fillers are mica for electrical parts, asbestos for heat resistance, glass fiber for strength and electrical properties, nylon, and graphite. Phenolics represent one of the best polymers for low-creep applications. Moldings have good strength, good gloss, and good temperature range (150°C wood filled; intermittent use 220°C), but are rather brittle. Applications include electrical circuit board, gears, cams, and car brake linings (when filled with asbestos, glass, metal powder, etc.). The cost is low and the compressive strength very high.

### **Polyester**

Polyester resins can be cured at room temperature with a hardener or alone at 70 to 150°C. It is used unfilled as a coating, for potting, encapsulation, linings, thread locking, castings, and industrial moldings. It is used mostly for glass-reinforced-plastic (GRP) moldings.

### **Polyimides**

Polyimides are noted for their unusually high resistance to oxidation and service temperatures up to 250°C (400°C for intermittent use). The low coefficient of friction and high resistance to abrasion make them ideal for nonlubricated hearings. Graphite or molybdenum disulfide filling improves these properties. They are used for high-density insulating tape. Polyimides have high strength, low moisture absorption, and resist most chemicals, except strong alkalis and ammonia solutions.

### **Silicones**

These may be cold or heat cured and are used for high-temperature laminates and electrical parts resistant to heat (heat distortion temperature 450°C). Unfilled and filled types are used for special-duty moldings. Organosilicones are used for surface coatings and as a superior adhesive between organic and nonorganic materials.

### **Laminated Polymer Structures**

A wide range of composite structures are prepared from polymer resins combined with fibers. The reader is referred to Section 12.6 for a more extensive discussion of polymer composites. Laminated polymer structures consist of layers of fibrous material impregnated with and bonded together usually by a thermosetting resin to produce sheets, bars, rods, tubes, etc. The laminate may be “decorative” or “industrial,” the latter being of load-bearing mechanical or electrical grade.

### **Phenolics**

Phenolic plastics can be reinforced with paper, cotton fabric, asbestos paper fabric or felt, synthetic fabric, or wood flour. They are used for general-purpose mechanical and electrical parts. They have good mechanical and electrical properties.

### **Epoxies**

These are used for high-performance mechanical and electrical duties. Fillers used are paper, cotton fabric, and glass fiber.

### **Tufnol**

“Tufnol” is the trade name for a large range of sheet, rod, and tube materials using phenolic resin with paper and asbestos fabric and epoxy resin with glass or fabric.

### **Polyester**

This is normally used with glass fabric (the cheapest) filler. The mechanical and electrical properties are inferior to those of epoxy. It can be rendered in self-colors.

### **Melamine**

Fillers used for melamine are paper, cotton fabric, asbestos paper fabric, and glass fabric. Melamines have a hard, nonscratch surface, superior electrical properties, and can be rendered in self-colors. They are used for insulators, especially in wet and dirty conditions, and for decorative and industrial laminates.

### **Silicone**

Silicone is used with asbestos paper and fabric and glass fabric fillers for high-temperature applications (250°C; intermittent use 300°C). It has excellent electrical but inferior mechanical properties.

### **Polyimide**

Polyimide is most often used with glass fabric as filler. Polyimides have superior thermal and electrical properties with a service temperature similar to that for silicones but with two to three times the strength and flexibility.

## Foam and Cellular Polymers

### Thermoplastics

*Polyurethane Foams.* The “flexible” type is the one most used. It is “open cell” and used for upholstery, underlays, thermal and vibration insulation, and buoyancy. It can be generated *in situ*. The rigid type has “closed cells” and is used for sandwich construction, insulation, etc. Molded components may be made from rigid and semirigid types.

*Expanded Polystyrene.* This material is produced only in rigid form with closed cells. It can be formed *in situ*. The density is extremely low, as is the cost. Chemical resistance is low and the service temperature is only 70°C. It is used for packaging, thermal and acoustic insulation, and buoyancy applications.

*Cellular Polyvinyl Chlorides.* The low-density type is closed cell and flexible. It is used for sandwich structures, thermal insulation, gaskets, trim, to provide buoyancy, and for insulating clothing. The moderate- to high-density open-cell type is similar to latex rubber and is used as synthetic leather cloth. The rigid closed-cell type is used for structural parts, sandwich construction, thermal insulation, and buoyancy. Rigid open-cell PVC (microporous PVC) is used for filters and battery separators. In general, cellular PVC has high strength, good flame resistance, and is easy to work.

*Polyethylene Foams.* The flexible type is closed cell and has low density with good chemical resistance and color availability, but is a poor heat insulator and is costly. The flexible foams are used for vibration damping, packaging, and gaskets. The rigid type has high density and is used for filters and cable insulation. A structural type has a solid skin and a foam core.

*Ethylene Vinyl Acetates.* These are microcellular foams similar to microcellular rubber foam, but are much lighter with better chemical resistance and color possibilities.

*Other Types.* Other types of thermoplastics include cellular acetate, which is used as a core material in constructions; expanded acrylics, which have good physical properties, thermal insulation, and chemical resistance; expanded nylon (and expanded ABS), which are low-density, solid-skin constructions; expanded PVA, which has similar properties to expanded polystyrene; and expanded polypropylene, which gives high-density foams.

### Thermosets

*Phenolics.* These can be formed *in situ*. They have good rigidity, thermal insulation, and high service temperature, but are brittle.

*Urea Formaldehyde (UF) Foam.* This is readily formed *in situ* and has good thermal insulation. It has open pores and is used for cavity-wall filling.

*Expanded Epoxies.* These have limited use because of their high cost. They give a uniform texture and good dimensional stability and are used for composite forms, e.g., with polystyrene beads.

*Silicon Foams.* These are rigid and brittle with a high service temperature (300°C; 400°C intermittent use). Their use is limited to high-temperature-resistant sandwich constructions. The flexible closed-cell type is costly but will operate up to 200°C and is used for high-temperature seals and gaskets.

### Elastomers

*Cellular Rubbers.* There are three types: *sponge*, solid rubber blown to give an open-cell structure, *foam*, a liquid rubber expanded to form open or closed cells which is stiffer than sponge; and *expanded*, a solid rubber blown with mainly closed cells, also it is stiffer than sponge. Uses include gaskets, seals, thermal insulation, cushioning, shock absorption, sound and vibration damping, buoyancy, and sandwich constructions.

## Elastomers

Elastomers, or rubbers, are essentially amorphous polymers with linear chain molecules with some cross-linking, which ensures elasticity and the return of the material to its original shape when a load is removed. They are characterized by large strains (typically 100%) under stress. The synthetic rubber styrene butadiene is the most-used elastomer, with natural rubber a close second. The following describes the commonly used elastomers and gives some applications and properties.

### Natural Rubbers (Polyisoprene, NR)

These elastomers have high strength, flexibility, and resilience, but have poor resistance to fuels, oils, flame, and sunlight aging. They are more costly than synthetic rubbers, which often replace them. "Soft-rubber" contains 1 to 4% sulfur as a vulcanizer. Wear resistance is increased by inclusion of fillers such as carbon black, silicon dioxide, clay, and wood flour. "Hard rubber" may contain up to 25% sulfur. Applications include vehicle tires and tubes, seals, antivibration mountings, hoses, and belts. Full vulcanization of 45% produces ebonite. Shore hardness: 30 to 90. Temperature range: -55 to 82°C.

### Synthetic Rubbers

*Styrene Butadiene Rubbers (SBR, GRS, BUNAS)*. These are similar to natural rubbers in application, but are usually inferior in mechanical properties, although cheaper. They are used in car brake hydraulic systems and for hoses, belts, gaskets, and antivibration mountings. Shore hardness: 40 to 80. Temperature range: -50 to 82°C.

*Butadiene Rubbers (Polynutadiene, BR)*. These are used as substitutes for natural rubber, but are generally inferior. They have similar applications as natural rubber. Shore hardness: 40 to 90. Temperature range: -100 to 93°C.

*Butyl Rubbers (Isobutylene Isoprene, GR I)*. These are extremely resistant to water, silicon fluids and grease, and gas permeation. They are used for puncture-proof tires, inner tubes, and vacuum seals. Shore hardness: 40 to 90. Temperature range: -45 to 150°C.

*Nitrile Rubbers (Butadiene Acrylonitrile, BUNA, N.NBR)*. These have good physical properties and good resistance to fuels, oils, solvents, water, silicon fluids, and abrasion. They are used for O rings and other seals, petrol hoses, fuel-pump diaphragms, gaskets, and oil-resistant shoe soles. Shore hardness: 40 to 95. Temperature range: -55 to 82°C.

*Neoprene Rubbers (Polychloroprene, Chloroprene)*. These are some of the best general-purpose synthetic rubbers. They have excellent resistance to weather aging, moderate resistance to oils, and good resistance to refrigerants and mild acids. Shore hardness: 40 to 95. Temperature range: -40 to 115°C.

*Chlorosulfonated Polyethylene Rubbers (CSM)*. These have poor mechanical properties but good resistance to acids and heat with complete resistance to ozone. They are used in chemical plants, tank linings, and high-voltage insulation. Shore hardness: 45 to 100. Temperature range: -100 to 93°C.

*Ethylene Propylene Rubbers (EP, FPM)*. These specialized rubbers are especially resistant to weather aging heat, many solvents, steam, hot water, dilute acids and alkalis, and ketones, but not petrol or mineral oils. They are used for conveyor belts, limited automotive applications, silicone fluid systems, and electrical insulation. Shore hardness: 40 to 90. Temperature hardness: -50 to 177°C.

*Fluorocarbon Rubbers*. These comprise a wide range of rubbers with excellent resistance to chemical attack, heat, acids, fuels, oils, aromatic compounds, etc. They have a high service temperature. They are particularly suitable for vacuum applications. Shore hardness: 60 to 90. Temperature hardness: -23 to 260°C.

*Isoprenes (Polyisoprene, IR)*. These are chemically the same as natural rubber but are more costly. The properties and applications are similar to those of natural rubber. Shore hardness: 40 to 80. Temperature hardness: -50 to 82°C.

*Polyacrylic Rubbers (ACM, ABR)*. This is a group of rubbers with properties midway between nitrile and fluorocarbon rubbers with excellent resistance to mineral oils, hypoid oils, and greases and good resistance to hot air and aging. The mechanical strength is low. They are often used for spark plug seals and transmission seals. Shore hardness: 40 to 90. Temperature hardness: -30 to 177°C.

*Polysulfide Rubbers.* These have poor physical properties and heat resistance, but good resistance to oils, solvents, and weathering and are impermeable to gases and moisture. They are used for caulking and sealing compounds and as a casting material. Shore hardness: 40 to 85. Temperature hardness:  $-50$  to  $121^{\circ}\text{C}$ .

*Polyurethane Rubbers.* These have exceptional strength and tear and abrasion resistance (the best of all rubbers), low-temperature flexibility, and good resistance to fuels, hydrocarbons, ozone, and weather. Resistance to solutions of acids and alkalis, hot water, steam, glycol, and ketones is poor. They are used for wear-resistant applications such as floor coverings. Shore hardness: 35 to 100. Temperature hardness:  $-53$  to  $115^{\circ}\text{C}$ .

*Silicone Rubbers (SI).* These have exceptionally high service-temperature ranges, but the mechanical properties and chemical resistance are poor. They cannot be used in applications which expose them to fuels, light mineral oils, or high-pressure steam. They are used for high- and low-temperature seals, high-temperature rotary seals, cable insulation, hydraulic seals, and aircraft door and canopy seals. Shore hardness: 30 to 90. Temperature hardness:  $-116$  to  $315^{\circ}\text{C}$  ( $380^{\circ}\text{C}$  for intermittent use).

*Fluorosilicone Rubbers.* These are similar to silicone rubbers but have better oil resistance and a lower temperature range. Shore hardness: 40 to 80. Temperature hardness:  $-64$  to  $204^{\circ}\text{C}$ .

## 12.3 Adhesives

---

*Richard L. Lehman*

### Introduction

Adhesives are substances capable of holding materials together in a useful manner by surface attachment. The principal attribute of adhesives is their ability to form strong bonds with surfaces of a wide range of materials and to retain bond strength under expected use conditions. Although most adhesives do not have excellent bulk properties and it is therefore important to keep adhesive films thin, some materials such as epoxies have bulk properties which qualify them as engineering materials and thus can be used in multifunctional applications.

### Advantages and Limitations of Use

The principal advantages of adhesives are their ability to bond similar to dissimilar materials of different thickness; to enable the fabrication of complex shapes not feasible by other fastening means; to smooth external joint surfaces; to permit economic and rapid assembly; to distribute stresses uniformly over joined interfaces, to provide weight reduction in critical structures via the elimination of fasteners; to dampen vibrations; to prevent or reduce galvanic corrosion; and to provide thermal and electrical insulation.

The limitations of adhesives depend on the specific adhesive and application and may include the necessity of surface preparation, long curing times, service-temperature limitations, loss of properties during service, toxicity of flammability during assembly or use, and the tendency of many adhesives to creep under sustained load.

### Classes of Adhesives

Thermoplastic adhesives are a general class of adhesives based upon long-chained polymeric structure, and are capable of being softened by the application of heat with subsequent hardening upon cooling (hot-melt adhesives). The softening process is reversible for numerous cycles, which facilitates assembly and disassembly of structures. Thermosetting adhesives are a general class of adhesives based upon cross-linked polymeric structures which develop strong bonds that cannot be reversibly broken once they are formed. Thus, the thermoset adhesives are incapable of being softened once solidified.

Thermoplastic and thermosetting adhesives are cured, a process often referred to as setting, by polymerization or solidification, by heat, catalysis, chemical reaction, free-radical activity, radiation, evaporation of solvent, or another process as governed by the chemical nature of the particular adhesive.

Elastomers are a special class of thermoplastic adhesive possessing the common quality of substantial flexibility or elasticity. Refer to Section 12.2 on polymers.

Anaerobic adhesives are a special class of thermoplastic adhesive, the polyacrylates, that set only in the absence of air (oxygen). The two basic types are (1) machinery — possessing shear strength only and (2) structural — possessing both tensile and shear strength.

Pressure-sensitive adhesives are permanently and aggressively tacky solids which form immediate bonds when two parts are brought together under pressure. They are available as films and tapes as well as hot-melt systems.

### Performance of Adhesives

To obtain optimum mechanical performance of an adhesive, it is critical to select the proper compound for the target application. [Table 12.3.1](#) illustrates compatibility of adhesives and five broad classes of common materials. Generally, for good adhesive bonds the chemistry of the adhesive must match or be

**TABLE 12.3.1 Relative Performance of Adhesive Resins**

Adhesive Resin	Adherence To:					Resistance			
	Paper	Wood	Metal	Ceramics	Rubbers	Water	Solvents	Alkali	Acids
Alkyd	6	7	5	6	7	7	2	2	5

**TABLE 12.3.2 High-Performance Engineering and Machine Part Adhesives**

Thread locking	• Anaerobic acrylic
Hub mounting	• Anaerobic acrylic — compatible materials or flow migration unimportant
	• Modified acrylic — large gaps or migration must be avoided
	• Epoxy — maximum strength at high temperatures
Bearing mounting	• Anaerobic acrylic — compatible materials necessary and flow into bearing area to be prevented
	• Modified acrylic — for lowest cost
Structural joining	• Epoxies and modified epoxies — for maximum strength (highest cost)
	• Acrylics — anaerobic or modified cyanacrylates
Gasketing	• Silicones — primarily anaerobic

similar to the surface energy, polarity, and/or chemistry of the material being bonded. The elastic modulus of the adhesive should not be greater than the bonded material.

Adhesives are used in two classes of application, those requiring only shear strength and those requiring structural properties, often tensile and shear strength. Table 12.3.2 provides a quick reference for some typical applications. A much more detailed summary and classification of adhesives is given in Table 12.3.3.

Table 12.3.3 presents a sample of a number of adhesives (with practical information) that are available from various sources. The table is adapted from the rather extensive one found in J. Shields, *Adhesives Handbook*, CRC Press, Boca Raton, FL, 1970. For other extensive lists of trade sources, the reader is

TABLE 12.3.3 Properties and Applications of Adhesive Materials

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
<b>Animal</b>					
Animal (hide)	Melted at 70–75°C; sets on cooling	<70	Paper, wood, textiles	Woodworking, carpet materials, paper, bookbinding	May be thinned with water
Animal (hide) + plasticizers	Applied as a melt at 60°C	<60	Paper, cellulosic materials	Bookbinding, stationery applications	Cures to permanent flexible film
Fish glue	1 hr at 20°C	<60	Wood, chipboard, paper	General-purpose for porous materials	Rapid setting; good flexibility, moderate resistance to water; high tack
Casein	Cold setting after 20 min standing period on mixing	<50	Timber with moisture content	Laminated timber arches and beams, plybox beams, and engineering timber work	Full bond strength developed after seasoning period of 48 hr
Casein + 60% latex	Cold setting after 20 min standing period on mixing	<60	Aluminum, wood, phenolic formaldehyde (rigid, leather, rubber)	Bonding of dissimilar materials to give flexible, water-resistant bond	Flexible
<b>Vegetable</b>					
Dextrine	Air drying		Paper, cardboard, leather, wood, pottery	General-purpose glue for absorbent materials	Medium drying period of 2–3 hr
Dextrine–starch blend	Applied above 15°C air drying	<48	Cellulosic materials, cardboard, paper	Labeling, carton sealing, spiral-tube winding	Fast setting; may be diluted with water
Gum arabic	Cold setting	<50	Paper, cardboard	Stationery uses	Fast drying
<b>Mineral</b>					
Silicate	8 hr at 20°C	10–430	Asbestos, magnesia	Lagging asbestos cloth on high-temperature insulation	Unsuitable where moisture; not recommended for glass or painted surfaces

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Silicate with china-clay filler	Dried at 80°C before exposure to heat	-180-1500	Asbestos, ceramics, brickwork, glass, silver, aluminum, steel (mild)-steel	General purpose cement for bonding refractory materials and metals; furnace repairs and gastight jointing of pipe work; heat-insulating materials	Resistant to oil, gasoline, and weak acids
Sodium silicate	Dried at 20-80°C before exposure to heat	0-850	Aluminum (foil), paper, wood-wood	Fabrication of corrugated fiber board; wood bonding, metal foil to paper lamination	Suitable for glass-to-stone bonding
Aluminum phosphate + silica filler	Dried 1/2 hr at 20°C, then 1/2 hr at 70°C + 1/2 hr at 100°C + 1 hr at 200°C + 1 hr at 250°C; repeat for two overcoatings and finally cure at 1 hr at 350°C	<750	Steels (low-alloy), iron, brass, titanium, copper, aluminum	Strain-gauge attachment to heat-resistant metals; heater-element bonding	Particularly suited to heat-resistant steels where surface oxidation of metal at high temperatures is less detrimental to adhesion
Bitumen/latex emulsion	Dried in air to a tacky state	0-66	Cork, polystyrene (foam), polyvinyl chloride, concrete, asbestos	Lightweight thermal-insulation boards, and preformed sections to porous and nonporous surfaces; building applications	Not recommended for constructions operated below 0°C
<b>Elastomers</b>					
Natural rubber	Air dried 20 min at 20°C and heat-cured 5 min at 140°C	<60	Rubber (styrene butadiene), rubber (latex), aluminum, cardboard, leather, cotton	Vulcanizing cement for rubber bonding to textiles and rubbers	May be thinned with toluene
Natural rubber in hydrocarbon solvent	Air dried 10 min at 20°C and heat-cured for 20 min at 150°C	<100	Hair (keratin), bristle, polyamide fiber	Brush-setting cement for natural- and synthetic-fiber materials	Resistant to solvents employed in oil, paint and varnish industries, can be nailed without splitting
Rubber latex	Air drying within 15 min	<60	Canvas, paper, fabrics, cellulosic materials	Bonding textiles, papers packaging materials; carpet bonding	Resistant to heat; should be protected from frosts, oils

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Chlorinated rubber in hydrocarbon solvents	Air dried 10 min at 20°C and contact bonded	-20-60	Polyvinyl chloride, acrylonitrile butadiene styrene, polystyrene, rubber, wood	General-purpose contact adhesive	Resistant to aging, water, oils, petroleum
Styrene-butadene rubber lattices	Air drying	-20-60	Polystyrene (foam), wood, hardboard, asbestos, brickwood	Bonding polystyrene foams to porous surface	—
Neoprene/nitrile rubbers in (?)	Dried 30 min in air and bonded under pressure; tacky	-20-60	Wood, linoleum, leather, paper, metals, nitrile rubbers, glass, fabrics	Cement for bonding synthetic rubbers to metals, woods, fabrics	May be thinned with ketones
Acrylonitrile rubber + phenolic resin	Primer air dried 60 min at 20°C, film cured 60 min at 175°C under pressure; pressure released on cooling at 50°C	-40-130	Aluminum (alloy)-aluminum to DTD 746	Metal bonding for structural applications at elevated temperatures	Subject to creep at 150°C for sustained loading
Polysulfide rubber in ketone solvent and catalyst	3 days at 25°C	-50-130, withstands higher temperatures for short periods	Metals	Sealant for fuel tanks and pressurized cabins in aircraft, where good weatherproof and waterproof properties are required	Resistant to gasoline, oil, hydraulic fluids, ester lubricants; moderate resistance to acids and alkalis
Silicone rubber	24 hr at 20°C (20% R.H.); full cure in 5 days	-65-260	Aluminum, titanium, steel (stainless), glass, cork, silicone rubber, cured rubber-aluminum, cured rubber-titanium, cured rubber-steel (stainless), aluminum-aluminum (2024 Alclad), cork-cork (phenolic bonded)	General-purpose bonding and sealing applications; adhesive/sealant for situations where material is expected to support considerable suspended weight; high-pressure exposure conditions	Resistant to weathering and moisture
Reclaim rubber	Contact bonded when tacky	<50	Fabric, leather, wood, glass, metals (primed)	General industrial adhesive for rubber, fabric, leather, porous materials	May be thinned with toluene
Polychloroprene	Air dried 10-20 min at 20°C	<60	Rubber, steel, wood, concrete	Bonding all types of rubber flooring to metals, woods, and masonry	Good heat resistance

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Modified polyurethane	3 hr at 18°C to 16 hr at -15°C	-80-110	Concrete, plaster, ceramics, glass, hardboards, wood, polyurethane (foam), phenol formaldehyde (foam), polystyrene (foam), copper, lead, steel, aluminum	Bonding to rigid and semirigid panels to irregular wall surfaces, wall cladding and floor laying; building industry applications	Foam remains flexible on aging even at elevated temperatures; will withstand a 12% movement
<b>Thermoplastic</b>					
Nitrocellulose in ester solvent	Heat set 1 hr at 60°C after wet bonding	60	Paper, leather, textiles, silicon carbide, metals	Labeling, general bonding of inorganic materials including metals	Good resistance to mineral oils
Modified methyl cellulose	Dries in air	<50	Vinyl-coated paper, polystyrene foam	Heavy-duty adhesive; decorating paper and plastics	Contains fungicide to prevent biodeterioration
Ethylene vinyl acetate copolymer + resins	Film transfer at 70-80°C followed by bonding at 150-160°C	60, or 1 hr at 90	Cotton (duck)-cotton, resin rubber-leather, melamine laminate-plywood, steel (mild)-steel, acrylic (sheet) acrylic	Metals, laminated plastics, and textiles; fabrication of leather goods; lamination work	Good electrical insulation
Polyvinyl acetate	Rapid setting	<60	Paper, cardboard	Carton sealing in packaging industry	Resistant to water
Synthetic polymer blend	Applied as a melt at 177°C	<70	Paper, cardboard, polythene (coated materials)	Carton and paperbag sealing; packaging	—
Polychloroprene/resin blend in solvent	Air dried 10 min at 20°C and cured 4 days at 20°C to 7 hr at 75°C	<70	Chlorosulfonated polythene, polychloroprene fabrics, polyamide fabrics, leather, wood, textiles	Bonding synthetic rubbers and porous materials; primer for polyamide-coated fabrics such as nylon, terylene	—
Polychloroprene	Air dried 10-20 min at 20°C	—	Rubber, steel, wood, concrete	Bonding all types of rubber flooring to metals, woods, and masonry	Good heat resistance
Saturated polyester + isocyanate catalyst in ethyl acetate	Solvent evaporation and press cured at 40-80°C when tacky	—	Cellulose, cellulose acetate, polyolefins (treated film), polyvinyl chloride (rigid), paper, aluminum (foil), copper (foil)	Lamination of plastic films to themselves and metal foils for packaging industry, printed circuits	Resistant to heat, moisture, and many solvents

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Cyanoacrylate (anaerobic)	15 sec to 10 min at 20°C substrate dependent	Melts at 165	Steel–steel, steel–aluminum, aluminum–aluminum, butyl rubber–phenolic	Rapid assembly of metal, glass, plastics, rubber components	Anaerobic adhesive. Curing action is based on the rapid polymerization of the monomer under the influence of basic catalysts; absorbed outer layer on most surfaces suffices to initiate polymerization and brings about bonding
Polyacrylate resin (anaerobic)	3 min at 120°C to 45 min at 65°C or 7 days at 20°C	–55–95	Aluminum–aluminum	Assembly requirements requiring high resistance to impact or shock loading; metals, glass and thermosetting plastics	Anaerobic adhesive
<b>Thermosetting</b>					
Urea formaldehyde	9 hr at 10°C to 1 hr at 21°C after mixing powder with water (22%)	<90	Wood, phenolic laminate	Wood gluing and bonding on plastic laminates to wood; plywood, chipboard manufacture; boat building and timber engineering	Excess glue may be removed with soapy water
Phenolic formaldehyde + catalyst PX-12	Cold acting	<100	Wood	Timber and similar porous materials for outdoor-exposure conditions; shop fascia panels	Good resistance to weathering and biodeterioration
Resorcinol formaldehyde + catalyst RXS-8	Cured at 16–80°C under pressure	<100	Wood, asbestos, aluminum, phenolic laminate, polystyrene (foam), polyvinyl chloride, polyamide (rigid)	Constructional laminates for marine craft; building and timber applications; aluminum–plywood bonding; laminated plastics	Recommended for severe outdoor-exposure conditions
Epoxy resin + catalyst	24–48 hr at 20°C to 20 min at 120°C	100	Steel, glass, polyester–glass fiber composite, aluminum–aluminum	General-purpose structural adhesive	—

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Epoxy resin + catalyst	8 hr at 24°C to 2 hr at 66°C to 45 min at 121°C	65	Steel, copper, zinc, silicon carbide, wood, masonry, polyester-glass fiber composite, aluminum-aluminum	Bonding of metals, glass, ceramics, and plastic composites	Cures to strong, durable bond
Epoxy + steel filler (80% w/w)	1–2 hr at 21°C	120	Iron, steel, aluminum, wood, concrete, ceramics, aluminum-aluminum	Industrial maintenance repairs; metallic tanks, pipes, valves, engine castings, castings	Good resistance to chemicals, oils, water
Epoxy + amine catalyst (ancamine LT)	2–7 days at 20°C for 33% w/w catalyst content	–5–60	Concrete stonework	Repair of concrete roads and stone surfaces	Excellent pigment-wetting properties; effective underwater and suited to applications under adverse wet or cold conditions
Epoxy resin (modified)	4–5 hr at 149°C to 20 min at 230°C to 7 min at 280°C	150	Aluminum, steel, ceramics	One-part structural adhesive for high-temperature applications	Good gap-filling properties for poorly fitting joints; resistant to weather, galvanic action
Epoxy	45 sec at 20°C	—	Gem stones, glass, steel, aluminum-aluminum	Rapid assembly of electronic components, instrument parts, printed circuits; stone setting in jewelry and as an alternative to soldering	—
Epoxy resin in solvent + catalyst	8 hr at 52°C to 1/2 hr at 121°C	–270–371	Aluminum and magnesium alloys for elevated-temperature service	Strain gauges for cryogenic and elevated-temperature use; micromasurement strain gauges	Cured material resists outgassing in high vacuum
Epoxy polyamide	8 hr at 20°C to 15 min at 100°C	100	Copper, lead, concrete, glass, wood, fiberglass, steel-steel aluminum-aluminum	Metals, ceramics, and plastics bonding; building and civil engineering applications	Resists water, acids, oils, greases

TABLE 12.3.3 Properties and Applications of Adhesive Materials (continued)

Basic Type	Curing Cycle, Time at Temperature	Service Temperature Range, C	Adherends	Main Uses	Remarks
Epoxy/polysulfide	24 hr at 20°C to 3 hr at 60°C to 20 min at 100°C	<120	Asbestos (rigid), ceramics, glass-fiber composites, carbon, polytetrafluoroethylene (treated), polyester (film), polystyrene (treated), rubber (treated), copper (treated), tungsten carbide, magnesium alloys, aluminum-aluminum, steel (stainless)-steel	Cold-setting adhesive especially suitable for bonding materials with differing expansion properties	Cures to flexible material; resistant to water, petroleum, alkalis, and mild acids
Phenol furfural + acid catalyst	2 days at 21°C	90-140	Alumina, carbon (graphite)	Formulation of chemically resistant cements; bedding and joining chemically resistant ceramic tiles	Extremely resistant to abrasion and heat
	Heated by air drying for several hours or 15-30 min at 210°F	—	<b>Pressure-sensitive</b> Teflon-Teflon, Teflon-metal	—	Good resistance to acids and alkalis; excellent electrical properties
Ceramic-based	Dried for 1/2 hr at 77°C and cured 1/2 hr at 200°C + 1 hr at 250°C; postcured, 1 hr at 350°C	816	<b>Miscellaneous</b>	Strain gauges, temperature sensors for elevated-temperature work	—
			Metals

## 12.4 Wood

---

*Daniel J. Strange*

### Definition

Wood is the structural component of a tree. It is composed of dead cells which were originally formed near the cambium (just beneath the bark). As the tree grows, the cambium moves outward, leaving the dead cells behind to serve as structure.

The two broad classifications for types of wood are softwoods and hardwoods. Softwoods come from conifers while hardwoods come from deciduous trees, and as the name implies softwoods are generally softer and hence weaker and with lower elastic modulus than hardwoods, although this generalization is not universally true.

The wood closest to the bark is called sapwood, and this layer extends about an inch into the tree. Although most of the cells in this layer are dead, this is the layer which transports moisture to the rest of the tree by capillary action. Beneath the sapwood layer is the heartwood, which is almost totally inactive except to provide structural support.

### Composition

Wood is a fibrous cellular material with the cell walls composed primarily of cellulose, hemicellulose, and lignin. Cellulose is a linear polymer of glucose units and is the single most common organic chemical in nature. It accounts for roughly 40 to 50% of the wood by weight. Hemicellulose is a modified form of cellulose comprising approximately 30% of the cell wall whose structure can vary depending upon the exact type of wood. Lignin is a complex three-dimensional phenolic polymer which composes 20 to 30% of the structure of the wood. The rest of the weight of the wood is composed primarily of extraneous extractive substances which reside within the cellular structure and affect properties such as specific gravity, moisture absorption, and durability.

Variations in the compositions, structures, and volumes of these four components can have dramatic effects on the properties of the wood. These properties are relatively constant within a species, although growing conditions can have a significant influence.

### Mechanical Properties

The properties of wood can vary substantially depending upon moisture content. “Green” wood, wood taken directly from a living tree with associated high moisture level, is significantly weaker (lower Young’s modulus, tensile strength, and compressive strength) than oven-dried wood. Typical ratios of dry to green wood strength properties vary from 1.2 to 1.8.

The failure modes of wood are more complex than one might expect. Because wood is essentially a composite material, it does not follow Hooke’s law at high stresses but instead exhibits viscoelastic behavior. [Figure 12.4.1](#) shows typical stress–strain curves for wood in tension and compression. At very high stresses, creep can occur. Wood is strongest in tension parallel to the grain, on the order of 100 MPa for a typical softwood. Perpendicular to the grain this value drops to about 4 MPa. In compression the strength values are approximately half the tension values, due to the collapse of the cellular structure and buckling of the wood fibers.

There are three principal shear failure modes in wood, six if one distinguishes between the radial and tangential directions. These modes are shear perpendicular to grain, shear parallel to grain, and rolling shear. Rolling shear occurs when the failure plane is parallel to the grain but the sliding direction is perpendicular to the grain, hence the fibers “roll” over each other. Wood is strongest when the shear is perpendicular to the grain, and weakest in rolling shear.

**FIGURE 12.4.1** Stress–strain behavior of wood in tension and compression. Stress–strain curves for wood in tension and compression parallel to grain. Signs of stress and strain have been ignored so that both may be plotted together. Note particularly the difference in strength and in the extent of the nonlinear deformation prior to maximum stress.

## Decay Resistance

Totally dry wood does not decay. Furthermore, wood kept completely submerged will not decay significantly. Wood decays most rapidly in warm, humid, low-altitude areas. Some species of wood are more decay resistant than others as a result of the presence of extractives. White oak, walnut, cherry, cedar, and yew are examples of highly decay-resistant woods. Pines, willows, elms, beeches, and spruces are examples of low decay-resistant woods.

## Composites

By gluing wood plies, chips, fibers, or pulp together a composite material can be formed which has more isotropic and homogenous properties than regular timber. In addition, this technique creates a strong and durable product out of wood unsuitable for timber. In general, wood composites homogenize the extreme anisotropy of timber into a nearly isotropic material whose properties are an average of the properties in each direction of the original timber. [Table 12.4.1](#) classifies the various wood composites based upon the constitutive particle and the binder.

The most common wood composite is paper. Paper is made from pulped and chemically treated cellulose fibers, which is then rolled into sheets, pressed, and dried. There is no glue involved, as the microfibrils of the cellulose interlock and form hydrogen bonds. Fiberboard is similar to paper, only thicker (by an arbitrary value, typically 0.012 in.) and with larger fiber bundles. *Hardboard* simply refers to a high-density fiberboard.

Wood chips and/or sawdust pressed and glued together is referred to as *particleboard*. Typically, the chips range in size from 10 to 300 mm long and are in the form of flakes or fibers. Particleboard is effectively isotropic, easily machineable, and inexpensive. It is often used in furniture and for floor underlayment. When larger wood chips are used the product is referred to as *flakeboard*.

Plywood is created by layering plies of radial-cut wood. Typically, the plies are oriented at 90° to each other, which results in a strong material when the stress is parallel or perpendicular to the grain of the face plies, but a lesser strength at any other angle. Some design strength specifications of plywood are given in [Table 12.4.2](#). Plywood makes efficient use of timber due to its radial cut, minimizes the effects of imperfections, resists warping, and can be formed into large sheets. Plywood is also less expensive than clear lumber.

The reader is referred to [Table C.14](#) in the Appendix for an overview of the physical properties and uses of American woods. The table also contains recommendations for appropriate applications. [Table E.1](#) in the Appendix gives nominal sizes for lumber and timber, as well as allowable stresses in tension and compression and moduli of elasticity of various kinds of woods.

**TABLE 12.4.1 Allowable Stresses for Plywood (Stresses in MPa)**

Type of Stress	Species Group of Face Ply	Grade Stress Level				
		S-1		S-2		S-3
		Wet	Dry	Wet	Dry	Dry Only
Tension in plane of plies (at 45° to face use 1/6 value)	1	9.86	13.79	8.20	11.38	11.38
	2,3	6.76	9.65	5.65	8.27	8.27

## 12.5 Portland Cement Concrete

Steven H. Kosmatka

### Introduction

Portland cement concrete is a simple material in appearance with a very complex internal nature. In contrast to its internal complexity, versatility, durability, and economy of concrete have made it the most-used construction material in the world. This can be seen in the variety of structures it is used in, from highways and bridges to buildings and dams.

Concrete is a mixture of portland cement, water, and aggregates, with or without admixtures. The portland cement and water form a paste that hardens as a result of a chemical reaction between the cement and water. The paste acts as a glue, binding the aggregates (sand and gravel or crushed stone) into a solid rocklike mass. The quality of the paste and the aggregates dictate the engineering properties of this construction material. Paste qualities are directly related to the amount of water used in relation to the amount of cement. The less water that is used, the better the quality of the concrete. Reduced water content results in improved strength and durability and in reduced permeability and shrinkage. As the fine and coarse aggregates make up 60 to 75% of the total volume of the concrete (Figure 12.5.1), their selection is important. The aggregates must have adequate strength and resistance to exposure conditions and must be durable.

FIGURE 12.5.1 Range of proportions of materials used in concrete. (From *Design and Control of Concrete Mixtures*, EB001, Portland Cement Association, Skokie, IL, 1992. With permission.)

### Fresh Concrete Properties

Freshly mixed concrete should be in a semifluid state capable of being molded by hand or mechanical means. All the particles of sand and coarse aggregate are encased and held in suspension. The ingredients should not segregate or separate during transport or handling. After the concrete hardens, it becomes a homogeneous mixture of all the components. Concrete of plastic consistency should not crumble, but flow sluggishly without segregation.

Concrete must be consolidated to form a homogeneous mass without the presence of large voids to achieve the desired strength and durability of the construction material. Internal and external vibration of concrete using vibrators allows stiff, slow-slump mixtures to be properly densified. The use of mechanical vibration provides an economical, practical method to quickly consolidate concrete without detrimentally affecting its properties.

### Hardened Concrete Properties

#### Strength

Concrete gains strength by the reaction between cement and water — called hydration. Portland cement is primarily a calcium silicate cement. The calcium silicate combines with water and forms calcium

silicate hydrate, which is responsible for the primary engineering properties of concrete, such as setting, hardening, strength, and dimensional stability. The compressive strength of concrete increases with age as long as an appropriate moisture content and temperature are available. This is illustrated in [Figure 12.5.2](#). Compressive strength is usually specified at the age of 28 days; however, depending on the project, ages of 3 and 7 days can also be specified. For general-use concrete, a 28-day compressive strength between 20 and 40 MPa (3000 and 6000 psi) is used. 28 MPa (4000 psi) is most common. Higher-strength concrete, 50 to 140 MPa (7000 to 20,000 psi), is used in special applications to minimize structural dimensions, increase abrasion resistance and durability, and minimize creep (long-term deformation).

**FIGURE 12.5.2** Concrete strength increases with age as long as moisture and a favorable temperature are present.

Increase in strength with age continues as long as any unhydrated cement is still present, the relative humidity in the concrete is approximately 80% or higher, and the concrete temperature is favorable. In order to maintain this increase in strength, concrete must be properly cured. Curing means that not only will a favorable temperature be present, but also moisture loss will not be permitted or extra water will be provided at the surface.

The compressive strength of concrete is directly related to the water/cement ratio. A decrease in water/cement ratio results in higher strength. Concrete achieves about 70 to 75% of its 28-day strength in 7 days. Although concrete is very strong in compression, it is weak in tensile strength. Tensile strength is about 8 to 12% of the compressive strength. Flexural strength is 0.7 to 0.8 times (for English units 5 to 7.5 times) the square root of the compressive strength. Shear strength is about 20% of the compressive strength. Modulus of elasticity ranges from 14,000 to 41,000 MPa and can be estimated as 5000 times the square root of the compressive strength (2 to 6 million psi or 57,000 times the square root of the compressive strength in English units). Refer to [Tables 12.5.1](#), [12.5.2](#), and [12.5.3](#).

**TABLE 12.5.1 Typical Properties of Normal-Strength Portland Cement Concrete**

Compressive strength	20–40 MPa (3000–6000 psi)
Flexural strength	3–5 MPa (400–700 psi)
Tensile strength	2–5 MPa (300–700 psi)
Modulus of elasticity	14,000–41,000 MPa (2–6 million psi)
Permeability	$1 \times 10^{-10}$ cm/sec
Coefficient of thermal expansion	$10^{-5}/^{\circ}\text{C}$ ( $5.5 \times 10^{-6}/^{\circ}\text{F}$ )
Drying shrinkage	$4\text{--}8 \times 10^{-4}$
Drying shrinkage of reinforced concrete	$2\text{--}3 \times 10^{-4}$
Poisson's ratio	0.20–0.21
Shear strain	6000–17,000 MPa (1–3 million psi)
Density	2240–2400 kg/m <sup>3</sup> (140–150 lb/ft <sup>3</sup> )

### Density

Normal-weight concrete has a density of 2240 to 2400 kg/m<sup>3</sup> (140 to 150 lb/ft<sup>3</sup>). The density of concrete varies with the relative density of the aggregate, the amount of air present in the paste, and the amount of water and cement in the mixture.

### Permeability

Concrete permeability is a function of the permeability of the paste and aggregate and the interface between them. Decreased permeability improves the resistance of concrete to saturation, sulfate attack, chemical attack, and chloride penetration. Paste permeability has the greatest influence on concrete permeability. Paste permeability is directly related to the water/cement ratio and the degree of hydration or length of moist curing. A low water cement ratio and an adequate moist-curing period result in concrete with low permeability (Figure 12.5.3). The water permeability of mature, good-quality concrete, is approximately  $1 \times 10^{-10}$  cm/sec.

### Abrasion Resistance

Abrasion resistance is directly related to the compressive strength of the concrete. The type of aggregate and the surface finish also have a strong influence on abrasion resistance. A hard aggregate, such as a granite, would provide more abrasion resistance than a soft limestone aggregate.

### Volume Change and Crack Control

Concrete changes slightly in volume for various reasons. Understanding the nature of these changes is useful in planning concrete work and preventing cracks from forming. If concrete is free to move, normal volume changes would have very little consequence; but since concrete in service is usually restrained by foundations, subgrades, reinforcement, or connecting elements, significant stresses can develop. As the concrete shrinks, tensile stresses develop that can exceed the tensile strength of the concrete, resulting in crack formation.

The primary factors affecting volume change are temperature and moisture changes. Concrete expands slightly as temperature rises and contracts as temperature falls. The average value for the coefficient of thermal expansion of concrete is about  $1.0 \times 10^{-5}/^{\circ}\text{C}$  ( $5.5 \times 10^{-6}/^{\circ}\text{F}$ ). This amounts to a length change of 5 mm for a 10-m length (0.66 in. for 100 ft) of concrete subjected to a rise or fall of 50°C (100°F). The thermal coefficient of expansion for steel is about  $1.2 \times 10^{-5}$  per degree Celsius ( $6.5 \times 10^{-6}/^{\circ}\text{F}$ ), comparable to that of concrete. The coefficient for reinforced concrete can be assumed as  $1.1 \times 10^{-5}/^{\circ}\text{C}$  ( $6 \times 10^{-6}/^{\circ}\text{F}$ ).

Concrete expands slightly with a gain in moisture and contracts with a loss in moisture. The drying-shrinkage of concrete specimens ranges from  $4$  to  $8 \times 10^{-4}$  when exposed to air at a 50% relative humidity. Concrete with a unit shrinkage of  $5.5 \times 10^{-4}$  shortens about the same amount as a thermal contraction caused by a decrease in temperature of 55°C (100°F). The shrinkage of reinforced concrete is less than that for plain concrete because of restraint offered by the reinforcement. Reinforced concrete structures with normal amounts of reinforcement have a drying-shrinkage in the range of  $2$  to  $3 \times 10^{-4}$ .

The amount of shrinkage is directly related to the amount of water in the concrete. Higher water content results in higher shrinkage. Specimen size also has an effect. Larger specimens shrink less than small specimens.

Drying-shrinkage is an inherent and unavoidable property of concrete; therefore, properly positioned reinforcing steel is used to reduce crack widths or joints are used to predetermine or control the location of cracks. Shrinkage control joints should be spaced about 25 to 30 times the thickness of a concrete slab on ground.

### Deformation and Creep

Concrete will deform a small amount when a load is placed on it. When concrete is loaded, the deformation caused by the load can be divided into two parts: a deformation that occurs immediately, such as elastic strain, and a time-dependent deformation that begins immediately but continues at a decreasing rate for as long as the concrete is loaded (Figure 12.5.4). This latter deformation is called creep. The amount of creep is dependent on the magnitude of the stress, the age and strength of the concrete when the stress is applied, and the length of time the concrete is stressed. Creep is of little concern for normal concrete pavements, bridges, and small buildings; however, creep should be considered in design for very tall buildings or very long bridges.

## Concrete Ingredients

### Portland Cements

Portland cements are hydraulic cements; that is, they set and harden by reacting with water. This reaction, called hydration, combines water and cement to form a stonelike mass. Portland cement was invented in 1824 by an English mason, Joseph Aspdin, who named his product portland cement because it produced a concrete that was of the same color as natural stone on the Isle of Portland in the English Channel.

Portland cement is produced by combining appropriate proportions of lime, iron, silica, and alumina and heating them. These raw ingredients are fed into a kiln that heats the ingredients to temperatures of 1450 to 1650°C (2600 to 3000°F) and changes the raw materials chemically into cement clinker. The clinker is cooled and then pulverized. During this operation a small amount of gypsum is added to control the setting of the cement. The finished pulverized product is portland cement. Portland cement is essentially a calcium silicate cement.

The American Society for Testing and Materials (ASTM) Standard C 150, Specification for Portland Cement, provides for the following types of portland cement:

- Type I General portland cement
- Type II Moderate-sulfate-resistant cement
- Type III High-early-strength cement
- Type IV Low-heat-of-hydration cement
- Type V High-sulfate-resistant cement

Types I, II, and III may also be designated as being air entraining. Type I portland cement is a general cement suitable for all uses where special properties of other cements are not required. It is commonly used in pavements, building, bridges, and precast concrete products.

Type II portland cement is used where precaution against moderate sulfate attack is important where sulfate concentrations in groundwater or soil are higher than normal, but not severe. Type II cement can also be specified to generate less heat than Type I cement. This moderate heat of hydration requirement is helpful when placing massive structures, such as piers, heavy abutments, and retaining walls. Type II cement may be specified when water-soluble sulfate in soil is between 0.1 and 0.2%, or when the sulfate content in water is between 150 and 1500 ppm. Types I and II are the most common cements available.

Type III portland cement provides strength at an early age. It is chemically similar to Type I cement except that the particles have been ground finer to increase the rate of hydration. It is commonly used in fast-track paving or when the concrete structure must be put into service as soon as possible, such as in bridge deck repair.

Type IV portland cement is used where the rate and amount of heat generated from hydration must be minimized. This low heat of hydration cement is intended for large, massive structures, such as gravity dams. Type IV cement is rarely available.

Type V portland cement is used in concrete exposed to very severe sulfate exposures. Type V cement would be used when concrete is exposed to soil with a water-soluble sulfate content of 0.2% and higher or to water with over 1500 ppm of sulfate. The high sulfate resistance of Type V cement is attributed to its low tricalcium aluminate content.

### **Blended Hydraulic Cements**

Blended hydraulic cements are produced by intimately blending two or more types of cementitious material. Primary blending materials are portland cement, ground granulated blast-furnace slag, fly ash, natural pozzolans, and silica fume. These cements are commonly used in the same manner as portland cements. Blended hydraulic cements conform to the requirements of ASTM C 595 or C 1157. ASTM C 5195 cements are as follows: Type IS — portland blast-furnace slag cement, Type IP and Type P — portland–pozzolan cement, Type S — slag cement, Type I (PM) — pozzolan-modified portland cement, and Type I (SM) — slag-modified portland cement. The most common blended cements available are Types IP and IS.

ASTM C 1157 blended hydraulic cements include the following: Type GU — blended hydraulic cement for general construction, Type HE — high-early-strength cement, Type MS — moderate-sulfate-resistant cement, Type HS — high-sulfate-resistant cement, Type MH — moderate-heat-of-hydration cement, and Type LH — low-heat-of-hydration cement.

### **Supplementary Cementing Materials (Mineral Admixtures)**

Supplementary cementing materials, also called mineral admixtures, are sometimes added to concrete mixtures. They contribute to the properties of hardened concrete through hydraulic or pozzolanic activity. Typical examples are natural pozzolans, fly ash, ground granulated blast-furnace slag, and silica fume. These materials react chemically with calcium hydroxide released from the hydration of portland cement to form cement compounds.

Below is a summary of the specifications and classes of supplementary cementing materials:

1. Ground granulated iron blast-furnace slag—ASTM C 989
  - Grade 80 — Slags with a low activity index
  - Grade 100 — Slags with a moderate activity index
  - Grade 120 — Slags with a high activity index
2. Fly ash and natural pozzolans — ASTM C 618
3. Class N — Raw or calcined natural pozzolans including diatomaceous earth, opaline cherts, shales, tuffs, volcanic ashes, and some calcined clays and shales
4. Class F — Fly ash with pozzolanic properties
5. Class C — Fly ash with pozzolanic and cementitious properties
6. Silica fume — ASTM C 1240

### **Mixing Water for Concrete**

Almost any natural water that is drinkable can be used as mixing water for making concrete. However, some waters that are not fit for drinking may be suitable for concrete. Reference 1 provides guidance concerning the use of waters containing alkali carbonates, chlorides, sulfates, acids, oils, and other materials, and provides guidance as to allowable levels of contamination.

### **Aggregates for Concrete**

The importance of using the right type and quality of aggregates cannot be overemphasized since the fine coarse aggregates occupy between 60 to 75% of the concrete volume and strongly influence the freshly mixed and hardened properties, mix proportions, and economy of the concrete. Fine aggregates consist of natural sand or crushed rock with particles smaller than 5 mm (0.2 in). Coarse aggregates

consist of a combination of gravel or crushed aggregate with particles predominately larger than 5 mm (0.2 in.) and generally between 10 and 13 mm ( $3/8$  and  $1/2$  in.). The most common coarse aggregate size is 19 and 25 mm ( $3/4$  and 1 in.) aggregate.

Normal weight aggregates should meet the requirements of ASTM C 33. This specification limits the amounts of harmful substances and states the requirements for aggregate characteristics, such as grading. The grading and maximum size of the aggregate affect the relative aggregate proportions as well as cement and water requirements, workability, pumpability, economy, shrinkage, and durability of the concrete.

### Chemical Admixtures for Concrete

Admixtures are ingredients in concrete other than portland cement, water, and aggregates that are added to the mixture immediately before or during mixing. Common chemical admixtures include air-entraining, water-reducing, retarding, accelerating, and superplasticizing admixtures. The major reasons for using admixtures are to reduce the cost of concrete construction, achieve certain properties in concrete more effectively than by other means, or to ensure the quality of concrete during the states of mixing, transporting, placing, or curing in adverse weather conditions. Refer to [Table 12.5.4](#).

Air-entraining admixtures are used purposely to entrain microscopic air bubbles in concrete. Air entrainment will dramatically improve the durability of concrete exposed to moisture during freezing and thawing. Air-entraining admixtures are commonly used to provide between 5 and 8% air content in concrete.

Water-reducing admixtures are used to reduce the quantity of mixing water required to produce concrete of a certain slump, reduce water/cement ratio, reduce cement content, or increase slump. Typical water-reducing admixtures reduce the water content by approximately 5 to 10%. High-range water reducers (superplasticizers) reduce the water content by approximately 12 to 30% and they can produce a highly fluid concrete.

Retarding admixtures are used to retard the rate of setting of concrete. An accelerating admixture is used to accelerate strength development of concrete at an early age.

### Proportioning Normal Concrete Mixtures

The objective in proportioning concrete mixtures is to determine the most economical and practical combination of readily available materials to produce a concrete that will satisfy the performance requirements under particular conditions of use. To fulfill these objectives a properly proportioned concrete mix should possess these qualities: (1) acceptable workability of freshly mixed concrete, (2) durability, strength, and uniform appearance of hardened concrete, and (3) economy. Only with proper selection of materials and mixture characteristics can the above qualities be obtained in concrete production.

The key to designing a concrete mixture is to be fully aware of the relationship between the water/cement ratio and its effect on strength and durability. The specified compressive strength at 28 days and durability concerns dictate the water/cement ratio established for a concrete mixture. The water/cement ratio is simply the weight of water divided by the weight of cement. If pozzolans or slags are used, it would include their weights and would be referred to as the water/cementitious material ratio. The water/cement ratio can be established by a known relationship to strength or by durability requirements. For example, a concrete structure may require only 20 MPa (3000 psi) compressive strength, which would relate to a water/cement ratio of about 0.6; however, if the concrete is exposed to deicers, the maximum water/cement ratio should be 0.45 ([Table 12.5.5](#)). For corrosion protection or reinforced concrete exposed to deicers, the maximum water/cement ratio should be 0.40. When designing concrete mixtures, remember that where durability is concerned, water/cement ratio should be as low as practical. Entrained air must be used in all concrete that will be exposed to freezing and thawing and

**TABLE 12.5.4 Concrete Admixtures by Classification**

Type of Admixture	Desired Effect	Material
Accelerators (ASTM C 494, Type C)	Accelerate setting and early-strength development	Calcium chloride (ASTM D 98) Triethanolamine, sodium thiocyanate, calcium formate, calcium nitrite, calcium nitrate
Air detrainers	Decrease air content	Tributyl phosphate, dibutyl phthalate, octyl alcohol, water-insoluble esters of carbonic and boric acid, silicones
Air-entrained admixtures (ASTM C 260)	Improve durability in environments of freeze-thaw, deicers, sulfate, and alkali reactivity Improve workability	Salts of wood resins (Vinsol resin) Some synthetic detergents Salts of sulfonated lignin Salts of petroleum acids Salts of proteinaceous material Fatty and resinous acids and their salts Alkylbenzene sulfonates Salts of sulfonated hydrocarbons
Alkali-reactivity reducers	Reduce alkali-reactivity expansion	Natural pozzolans, fly ash, silica fume, blast-furnace slag, salts of lithium and barium
Bonding admixtures	Increase bond strength	Rubber, polyvinyl chloride, polyvinyl acetate, acrylics, butadiene-styrene copolymers
Coloring agents	Colored concrete	Modified carbon black, iron oxide, phthalocyanine, umber, chromium oxide, titanium oxide, cobalt blue (ASTM C 979)
Corrosion inhibitors	Reduce steel corrosion activity in a chloride environment	Calcium nitrite, sodium nitrite, sodium benzoate, certain phosphates or fluorosilicates, fluoroaluminates
Dampproofing admixtures	Retard moisture penetration into dry concrete	Soaps of calcium or ammonium stearate or oleate Butyl stearate Petroleum products
Finely divided mineral admixtures		
Cementitious	Hydraulic properties Partial cement replacement	Ground granulated blast-furnace slag (ASTM C 989) Natural cement Hydraulic hydrated lime (ASTM C 141)
Pozzolans	Pozzolanic activity Improve workability, plasticity, sulfate resistance; reduce alkali reactivity, permeability, heat of hydration Partial cement replacement Filler	Diatomaceous earth, opaline cherts, clays, shales, volcanic tufts, pumicites (ASTM C 618, Class N); fly ash (ASTM C 618, Classes F and C), silica fume
Pozzolanic and cementitious	Same as cementitious and pozzolan categories	High calcium fly ash (ASTM C 618, Class C) Ground granulated blast-furnace slag (ASTM C 989)
Nominally inert	Improve workability Filler	Marble, dolomite, quartz, granite
Fungicides, germicides, and insecticides	Inhibit or control bacterial and fungal growth	Polyhalogenated phenols Dieldrin emulsions Copper compounds
Gas formers	Cause expansion before setting	Aluminum powder Resin soap and vegetables or animal glue Saponin Hydrolyzed protein
Grouting agents	Adjust grout properties for specific applications	See Air-entraining admixtures, Accelerators, Retarders, Workability agents
Permeability reducers	Decrease permeability	Silica fume (ASTM C 1240) Fly ash (ASTM C 618) Ground slag (ASTM C 989) Natural pozzolans (ASTM C 618)

**TABLE 12.5.4 Concrete Admixtures by Classification (continued)**

Type of Admixture	Desired Effect	Material
Pumping aids	Imnprove pumpability	Water reducers
		Latex
		Organic and synthetic polymers
		Organic flocculents
		Organic emulsions of paraffin, coal tar, asphalt, acrylics
		Bentonite and pyrogenic silicas
		Natural pozzolans (ASTM C 618, Class N)
Retarders (ASTM C 494, Type B)	Retard setting time	Fly ash (ASTM C 618, Classes F and C)
		Hydrated lime (ASTM C 141)
		Lignin
		Borax
		Sugars
		Tartaric acid and salts
		Superplasticizers <sup>a</sup> (ASTM C 1017, Type 1)
Superplasticizer <sup>a</sup> and retarder (ASTM C 1017, Type 2)	Flowing concrete with retarded set Reduce water	See Superplasticizers and also Water reducers
Water reducer (ASTM C 494, Type A)	Reduce water demand at least 5%	Lignosulfonates Hydroxylated carboxylic acids Carbohydrates (Also tend to retard set so accelerator is often added)
Water reducer and accelerator (ASTM C 494, Type E)	Reduce water (minimum 5%) and accelerate set	See Water reducer, Type A (Accelerator is added)
Water reducer and retarder (ASTM C 494, Type D)	Reduce water (minimum 5%) and retard	See Water reducer, Type A
Water reducer — high range (ASTM C 494, Type F)	Reduce water demand (miniumum 12%)	See Superplasticizers
Water reducer — high range — and retarder (ASTM C 494, Type G)	Reduce water demand (miniumum 12%) and retard set	See Superplasticizers and also Water reducers
Workability agents	Improve workability	Air-entraining admixtures Finely divided admixtures, except silica fume Water reducers

<sup>a</sup> Superplasticizers are also referred to as high-range water reducers or plasticizers. These admixtures often meet both ASTM C 494 and C 1017 specifications simultaneously.

the presence of deicing chemicals. A typical air content for concrete would range from 5 to 8%. Reference 1 provides step-by-step procedures for proportioning concrete. Refer to [Tables 12.5.6, 12.5.7, and 12.5.8](#).

## Mixing, Transporting, and Placing Concrete

All concrete should be mixed thoroughly until it is uniform in appearance with all ingredients evenly distributed. If concrete has been adequately mixed, samples taken from different portions of a batch will have essentially the same unit weight, air content, slump, and strength. Concrete is sometimes mixed at a job site at a stationary mixer or paving mixer, and other times it is mixed in central mixers at ready-mix plants (ASTM C 94). Once concrete is transported to a job site it is then conveyed by a variety of methods including belt conveyors, buckets, shoots, cranes, pumps, wheelbarrows, and other equipment.

**TABLE 12.5.5 Relationships Between Water Cement Ratio and Compressive Strength of Concrete**

Compressive Strength at 28 days, MPa (psi)	Water-Portland Cement Ratio, by Mass	
	Non-Air-Entrained Concrete	Air-Entrained Concrete
40 (5800)	0.42	—
35 (5100)	0.47	0.39
30 (4400)	0.54	0.45
25 (3600)	0.61	0.52
20 (2900)	0.69	0.60
15 (2200)	0.79	0.70

*Note:* Strength is based on 150 × 300-mm cylinders moist cured 28 days at 23 ± 2°C. Relationship assumes maximum size of aggregate about 25 mm.

Adapted from *Design and Control of Concrete Mixtures*, EBDD1, Portland Cement Association, Skokie, IL, 1992. With permission.

Concrete should be conveyed in a manner in which the concrete is not allowed to dry out, be delayed, or allowed to segregate before it is placed.

## Curing

All concrete must be properly cured. Curing is the maintenance of a satisfactory moisture content and temperature in concrete during some definite time period immediately following placing and finishing so that the desired properties of strength and durability may develop. Concrete should be moist cured for 7 days at a temperature between 10 and 27°C (50 and 80°F). Common methods of curing include ponding, spraying, or fogging; use of wet covers, impervious paper, plastic sheets, and membrane-forming curing compounds; or a combination of these.

## Durability

### Freeze-Thaw and Deicer Scaling Resistance

As water freezes in wet concrete, it expands 9%, producing hydraulic pressures in the cement paste and aggregate. Accumulated effects of successive freeze-thaw cycles and disruption of the paste and aggregate eventually cause significant expansion and extensive deterioration of the concrete. The deterioration is visible in the form of cracking, scaling, and crumbling.

The resistance of hardened concrete to freezing and thawing in a moist condition, with or without the presence of deicers, is significantly improved by the use of entrained air. Air entrainment prevents frost damage and scaling and is required for all concretes exposed to freezing and thawing or deicer chemicals. An air content of between 5 and 8% should be specified. Air-entrained concrete should be composed of durable materials and have a low water/cement ratio (maximum 0.45), a minimum cement content of 335 kg/m<sup>3</sup> (564 lb/yd<sup>3</sup>) or more, proper finishing after bleed water has evaporated from the surface, adequate drainage, a minimum of 7-days moist curing at or above 10°C (50°F), a minimum compressive strength of 28 MPa (4000 psi), and a minimum 30-day drying period after moist curing. Sealers may also be applied to provide additional protection against the effects of freezing and thawing and deicers. However, a sealer should not be necessary for properly proportioned and placed concrete.

### Sulfate-Resistant Concrete

Excessive amounts of sulfates in soil or water can, over 5 to 30 years, attack and destroy concrete that is not properly designed. Sulfates attack concrete by reacting with hydrated compounds in the hardened cement paste. Due to crystallization growth, these expansive reactions can induce sufficient pressure to

disrupt the cement paste, resulting in cracking and disintegration of the concrete. The first defense against sulfate attack is to use a low water/cement ratio (0.45 or preferably less), and to select a Type II or V cement (see the section on cement).

### Corrosion Protection

Concrete protects embedded steel from corrosion through its highly alkaline nature. The high-pH environment (usually greater than 12.5) causes a passive and noncorroding protective oxide film to form on steel. However, carbonation or the presence of chloride ions from deicers or seawater can destroy or penetrate the film, causing rusting of the reinforcing steel. In addition to using a water/cement ratio of 0.40 or less, the following protective strategies can be used individually or in combination to reduce the risk of corrosion:

1. Cover thickness of 90 mm (3.5 in.) or more of concrete over top, reinforcing steel of compression zones. [Note: Excessive cover in tension zones exacerbates surface crack width.]
2. Low-slump dense concrete overlay
3. Latex-modified concrete overlay
4. Interlayer membrane/asphaltic concrete systems
5. Epoxy-coated reinforcing steel
6. Corrosion-inhibiting admixtures in concrete
7. Sealers with or without overlay
8. Silica-fume or other pozzolans that significantly reduce concrete permeability
9. Low water/cement ratio (<0.35) superplasticized concrete
10. Cathodic protection
11. Polymer concrete overlay

12. Galvanized reinforcing steel
13. Polymer impregnation
14. Lateral and longitudinal prestressing for crack control
15. Blended cements containing silica fume or other pozzolans to reduce permeability

### Alkali-Silica Reaction

Most aggregates are chemically stable in hydraulic cement concrete, without deleterious interaction with other concrete ingredients. However, this is not the case for aggregates containing certain siliceous substances that react with soluble alkalis in concrete. Alkali-silica reactivity (ASR) is an expansive reaction between reactive forms of silica in aggregate and alkali hydroxides in concrete. Very reactive aggregates can induce cracks within a year, whereas slowly reactive aggregates can take over 20 years to induce noticeable cracks. ASR is best controlled through the use of fly ash, slag, silica fume, natural pozzolans, or blended hydraulic cement. With proper care in analyzing aggregates and selecting appropriate concrete ingredients, ASR can be effectively minimized using available materials. Reference 2 provides guidance on ASR.

## 12.6 Composites

### Introduction

*Victor A. Greenhut*

A composite material is a macroscopic, physical combination of two or more materials in which one material usually provides reinforcement. Composites have been developed where no single, quasi-continuous material will provide the required properties. In most composites one phase (material) is continuous and is termed the *matrix*, while the second, usually discontinuous phase, is termed the *reinforcement*, in some cases *filler* is applied when the reinforcement is not a quasi-continuous fiber. Matrix-filler nomenclature is one method of categorization. This yields the categories *metal matrix* (MMC), *polymer (plastic) matrix* (PMC), and *ceramic matrix* (CMC) composites — the major subdivisions of this section. Other categories are given the shape and configuration of the reinforcing phase. The reinforcement is usually a ceramic and/or glass. If it is similar in all dimensions, it is a *particulate-reinforced* composite; if needle-shaped single crystals, it is *whisker-reinforced*; if cut continuous filament, *chopped fiber-reinforced*; and if continuous fiber, *fiber composite*. For fiber composites configuration gives a further category. If fibers are aligned in one direction, it is a *uniaxial fiber composite*; if arranged in layers, it is a *laminar composite*; if a three-dimensional arrangement, it is a *3D weave composite*. Laminates and 3D weaves can be further divided by the weave used for the fiber.

Composites are not new materials. Perhaps the first important engineering structural composite was the Biblical straw-reinforced, sun-dried mud brick — adobe. Laminated structures such as bows have been used since prehistoric times. In the early 1900s doped fabric was employed in early aircraft surfaces. Reinforced phenolics were developed in the 1930s and glass-reinforced plastics in the 1940s. More recently, emphasis turned to reinforcements, with graphitic and boron-based fibers developed in the 1960s. High-performance aramids, such as Kevlar™, were developed in the 1970s. This and the previous decade have seen new developments in both fiber and matrix with lightweight aerospace MMCs and high-temperature CMCs showing major advances.

This section will concentrate on advanced composites in which major structural performance is achieved, but it should be noted that the largest tonnage and dollar value of composites is driven by the cost of materials. Polymers are reinforced with glass particulate or chipped fiber because it lowers the price per pound of a plastic, hence the term *filler* for reinforcement material. The structural properties are also improved, as PMCs show increased stiffness (resistance to bending) and strength (resistance to failure). These and other properties will receive the emphasis in this section. In MMCs high hardness, maintenance of hardness at elevated temperature, and precise tolerance are often lead properties, although stiffness and strength are important. The metal matrix confers some ductility so that the catastrophic failure of a solely ceramic material is avoided. In CMCs the reinforcement is chiefly incorporated to prevent catastrophic failure to introduce a more predictable failure stress (increased reliability), and to a lesser extent to increase strength. Particulate-reinforced plastics and fiberglass (glass fiber-reinforced plastic) have become commonplace engineering materials, as have ceramic-reinforced metal matrices (cemented carbides and cermets). Reinforcement with graphite and other advanced technology fibers has emerged for aerospace applications, biomedical use, and high-performance/high-cost consumer products such as sporting goods. Fiber-reinforced MMCs and ceramic-ceramic composites have developed greatly, but are still quite limited in application to very advanced technologies which can bear relatively high costs.

An important consideration for composite production is the bond between the matrix and the reinforcement. For MMCs and PMCs load must be transferred (Figure 12.6.1) to the relatively high-strength, high-elastic-modulus ceramic or glass in order to maximize the mechanical performance. For best transfer there must be no relative sliding or interface failure, so the strain at the matrix-to-reinforcement area can be maximum and equal ( $\epsilon_{\text{matrix}} = \epsilon_{\text{reinforcement}} = \epsilon_{m,c}$ ). This means that the reinforcement bears the major portion of the load,  $\sigma_c$ , while the weaker matrix bears a lower load,  $\sigma_m$ , because it has lower modulus.

**FIGURE 12.6.1** In a composite with good bonding between high-modulus ceramic and low-modulus metal or polymer matrix the interfacial strain must be the same. Thus, the high-strength ceramic fiber bears most of the load (stress).

To accomplish load transfer the bond interface must be engineered because metal and polymers do not show intrinsic bonding to ceramic reinforcement. A *coupling agent*, often a xylene, is applied to the ceramic or glass to promote bonding to a polymer. For metals, a metal matrix often has to be selected because it will wet and bond to the selected ceramic when molten or sintering during fabrication. Commonly, a controlled “forming gas” atmosphere must be used to produce MMCs composites so that a strong metal-to-ceramic bond is made.

The situation is somewhat different for ceramic–ceramic composites. These materials usually bond strongly to each other during fabrication. However, unlike the PMCs and MMC a less perfect bond is required. This is because local failure is required between matrix and reinforcement to introduce toughness or noncatastrophic fracture. This will be discussed further in the section on CMCs.

## Polymer Matrix Composites

*Weiping Wang, R. Allan Ridilla, and Mathew B. Buczek*

### Introduction

PMCs are used extensively as commodity and specialty engineering materials and constitute the largest class of composite materials on a dollar basis. The enormous success of PMCs arises from the wide range of properties which can be obtained and the low cost of low-end materials, such as fiberglass-reinforced polyester. Furthermore, the combination of high-strength/high-stiffness fibers in commodity polymer matrices offers an outstanding example of the composite principle — taking the best properties of both materials. The result is a strong, tough, stiff material which, depending on the matrix and reinforcement type, provides value in applications as diverse as consumer products, construction, and aerospace.

A distinction must be made between reinforced plastics and advanced composites. The term *reinforced plastics* generally refers to plastic materials fabricated with a relatively low percentage of discontinuous, randomly oriented fibers, with rather moderate properties, and used in commodity applications. *Advanced composites*, on the other hand, refers to a class of materials where a high percentage of continuous, highly oriented fibers are combined with a suitable polymeric matrix to produce articles of high specific strength and specific stiffness. At present, composites are widely used in the aerospace and sporting

**FIGURE 12.6.2** The evolution of carbon fiber composite applications since 1970 with fiber price and industry volume illustrated. (Source: Zoltek Co. Inc.)

goods industries for their superior performance. [Figure 12.6.2](#) illustrates the evolution of applications for carbon fibers.

Polymers are also often “filled” with particulate reinforcements to increase certain properties, such as deflection temperature under load (DTUL). Although these materials are formally composites, they are usually regarded as filled polymers and not composites and thus will not be discussed explicitly in this section. Refer to the polymer section of this chapter.

### Architecture

Each of the constituent materials in advanced composites must act synergistically to provide aggregate properties that are superior to the materials individually. The functional effectiveness of composites is principally due to the anisotropy of the materials and the laminate concept, where materials are bonded together in multiple layers. This allows the properties to be tailored to the applied load so that the structure can be theoretically more efficient than if isotropic materials were used. The reinforcements come in a variety of forms. Unidirectional tapes with all fibers along a common axis, woven fabrics constructed with fibers along both axes in the  $x$ - $y$  plane, and 3-D architectures with reinforcements in more than two axial directions are just a few of the building blocks of composite structures.

The concept of laminate is illustrated in [Figure 12.6.3](#). On the left is the unidirectional composite where all reinforcements are aligned in one direction. This construction provides excellent properties in the fiber direction but is limited to the properties of the resin in the transverse directions. The cross-ply construction on the right creates a structure that has common properties in the  $x$ - and  $y$ -direction but is limited to the characteristics of the resin in the  $z$ -direction. A large number of variations exist, allowing the designer to tailor the properties of the structure by varying the type of fibers and fiber orientations. Shown in [Figure 12.6.4](#) are typical values of specific tensile strength (strength-to-density ratio) and specific tensile modulus (modulus-to-density ratio) for 65% volume fraction, cross-ply quasi-isotropic composites. Also included in the plot for comparison are properties of mild steel, titanium (Ti-6Al-4V), and aluminum (2024-T6). The actual properties of a composite will vary significantly due to flaws created during processing.

In selecting polymer composite materials for design, one should consider both the potential advantages and concerns typical to composites as illustrated in [Table 12.6.1](#). Clearly, the advantages of materials should be put into use to achieve higher levels of performance in many kinds of products. On the other

FIGURE 12.6.3 The basic concept of composite laminate.

FIGURE 12.6.4 A comparative plot of specific tensile strength (strength-to-density) and specific tensile modulus (modulus-to-density) of composite material.

hand, potential issues in higher raw material cost and lower production volume and yield should also be weighed.

**Fiber**

*Introduction.* The most common reinforcement in polymer composites are fibers. Fibrous reinforcements come from compounds of light elements, (e.g., B, C, Si, O). These compounds typically contain

**TABLE 12.6.1 Advantages and Limitations of Polymer Matrix Composites**

Potential Advantages	Potential Limitations
High strength-to-density ratio	Low-volume production methods
High stiffness-to-density ratio	High raw material cost
Excellent corrosion resistance	Poor impact resistance
Good fatigue resistance	Poor high-temperature performance
Low thermal expansion	Delamination/out-of-plane loading

stable covalent bonds which impart greater strength and stiffness compared with metallic or ionic bonds. The compounds are processed to the final usable form of a fiber or filament with a highly aligned and directional microstructure so that the strength and stiffness properties are optimized along the fiber axis. Glass, graphite/carbon, aramid, and boron are among most notable fibers currently used in polymer composites.

*Glass Fiber.* Glass fiber reinforcements represent the largest volume used in the composites industry. These fibers are characterized by their low cost, clear to white color, good mechanical and electrical properties, high moisture and chemical resistance, and excellent dimensional stability with operational service to 550°C. Manufacturing of the fibers begins with molten glass which is drawn through a furnace into a fibrous form of final diameter of about 10 μm and then quenched to secure the final amorphous microstructure prior to applying final coatings or sizing. Common types of commercially available glass fiber are E-glass and S-glass, both of which are low alkali boro-alumino-silicate glasses. E-glass fiber, the workhorse of glass fiber applications, is the lower-cost fiber and is used in both structural and electrical applications. S-glass provides higher tensile properties and increased temperature resistance needed for aerospace and aircraft applications with a price premium. Representative properties for the glass fibers are shown in Table 12.6.2.

**TABLE 12.6.2 Fibers Used in Polymer Composites — Mechanical Properties**

	E-Glass	S-Glass	AS4 PAN-Based Carbon	IM7 PAN-Based Carbon	P120 Pitch-Based Graphite	Kevlar- 49	Boron

*Carbon Fiber.* Graphite/carbon fibers are the reinforcement of industrial choice for advanced composite applications where stiffness and performance are critical. Typical attributes of these fibers are excellent tensile strength and elastic modulus, ease of handling, black color, and a wide range of properties and cost. Graphite fibers are initially formed as from polymer precursor compounds such as polyacrylonitrile (PAN) or rayon and pitch, an amorphous, aromatic by-product of petroleum distillation. PAN-based graphite fiber, the predominant commercial fiber, starts with the liquid PAN polymer, which is spun into a fiber and stretched to align the microstructure. It is then stabilized and the microstructure is aligned at 400 to 500°F in an oxidizing atmosphere under tension. Next, carbonization occurs in an inert atmosphere at 1800 to 2300°F to remove most noncarbon elements. Finally, the graphitization step is performed on the carbon fiber by applying tension to the fiber in an inert atmosphere at 3600 to 6500°F. The result is a highly aligned, highly graphitic fiber with preferred graphite orientation along the fiber axis. The temperature and tension fabrication parameters of the graphitization step, along with the purity of the initial PAN polymer, are the variables which are modified to differentiate “low-end” (low strength,

modulus, cost) from the “high-end” fiber (high strength, modulus, cost) and all of the grades in between. Typical properties of several commercial grades of carbon/graphite fiber are listed in [Table 12.6.2](#).

**Aramid Fibers.** The aramid fiber derives its properties from long, rodlike aromatic polyamides. These fibers are characterized by low density, white yellow color, extremely high tensile properties, poor compressive strength, and high toughness, and they are difficult to cut mechanically. The manufacturing process for these fibers involves complex polymerization steps as the liquid polymer in acid is extruded or spun into a fiber form, water washed, dried, and finally heat treated under tension. The result is a highly aligned radial system of axially pleated lamellae in the microstructure. Aramid fibers have proved extremely useful in tension-critical application where the intrinsic compressive weaknesses of the fiber cannot be exploited. Commercially known as Kevlar, the most notable applications for aramid fibers are bulletproof vests (without matrix), and various high-pressure composite vessels. Typical properties for Kevlar 49 are listed in [Table 12.6.2](#).

**Boron Fibers.** Boron reinforcements are referred to as filaments rather than fibers since they are made by the chemical vapor deposition of boron onto a fine tungsten wire. This fabrication process produces a large-diameter, stiff, and expensive reinforcement that is somewhat difficult to handle and produce into subsequent product forms such as fabrics and contoured structures. Although boron filaments possess the combination of high strength and high specific modulus that glass could not achieve, its use has been reduced to a minuscule level. Carbon/graphite fiber varieties have supplanted boron where high specific modulus is a requirement. A small volume of boron filaments still remain in a handful of military aircraft as well as in some recreational products such as golf club shafts. Typical properties of boron filaments are shown in [Table 12.6.2](#).

## Polymer Matrix Materials

**Introduction.** While fibers provide much of the strength and stiffness in advanced composites, equally important is the matrix resin. The matrix holds the fiber network together, to protect the structure from environmental attack and to support the fibers so that loads can be transferred throughout the structure through a shear mechanism. Polymeric matrices can either be thermoset or thermoplastic resins.

Thermosets cannot be reformed or thermally reworked after polymerization (curing). They are subdivided into categories based on their chemical reactions. The first are addition-type polymers, generally considered easier to process, where two (or more) reactants combine to form the final cured product. The second is the condensation type, in which the reactants combine to form products in addition to water and other volatile constituents. These systems are more difficult to process due to the required management of the volatile to minimize process defects such as porosity.

Thermoplastic materials, on the other hand, are polymers which can be softened and melted with the application of heat. Although they can be recycled, thermoplastic matrices have found more-limited applications in the advanced composite applications since they are particularly susceptible to attack by fluids and to creep at high stresses, and are relatively difficult to handle in laminate or structural form prior to final consolidation. The remainder of this discussion will focus on thermoset matrices which account for more than 90% of present-day advanced composite applications. Three principal organic matrix materials will be discussed: polyesters, epoxies, and polyimides.

**Polyester Matrix.** Low-cost polyester resins constitute the highest volume usage for the general composite industry. There are many resins, formulations, curatives, and other additive constituents that provide a wide array of properties and performance characteristics, such as mechanical strength, toughness, and heat resistance. The vast majority of applications utilize glass since its interfacial adhesion to these resins has been optimized by the development of silane surface treatments. These resins when combined with glass have found wide application in the chemical processing construction, and marine industries where cured properties and low cost are tailor-made for design requirements. Applications with carbon/graphite and aramid fibers are far less frequent since adhesion to these fibers is generally

poor and cure shrinkage on these resins is quite high. Additionally, structures requiring the high performance of carbon/graphite can often justify the use of more-expensive epoxy resins.

*Epoxy Matrix.* Epoxy resins are the prevalent polymer used with advanced composites. Their extensive use is primarily due to their superior mechanical properties, excellent adhesion, good processibility utilizing addition-type reactions, low cure shrinkage and low cost. When choosing epoxy resins two elements are crucial: the base resin and the curing agent or hardener. Since there are many base resins and curing agents, the following general relationships are given to provide a practical framework when utilizing epoxy compounds:

- *Chemistry:* Aromatic compounds are more thermally stable, stronger, and more resistant to fluids than are aliphatics.
- *Cross-link density:* Higher-temperature cures and longer cure times will increase cross-link density and therefore strength/modulus, service temperature, and chemical resistance.
- *Curing agents:* Amine-cured systems have better chemical resistance and superior thermal stability, but are more brittle than anhydride-cured systems.

Epoxies are categorized by the cure temperature. The “250 F epoxies” are those that cure at 250°F and are suitable for service up to 250°F. The “350 F epoxies” are those with higher processing and service temperatures. One of the design concerns with epoxies is moisture absorption. The effects of moisture often require design stresses to be reduced in applications where moisture is a concern. Modern epoxy formulations include lower cost, higher toughness, and other properties which continue to make epoxies attractive to the end user.

Polyimide resins span the temperature spectrum from 350 to 600°F. There are three general types of polyimides:

1. *Addition-reaction* polyimides such as bismaleimides (BMI)
2. *Condensation-reaction* polyimides such as commercial Monsanto Skybond resin
3. *Combination* condensation/addition-reaction polyimides such as PMR-15

BMIs are similar to epoxies in that they undergo addition reactions, are easy to process, and share many of the handling characteristics that make epoxies desirable. These materials are the composite resins of choice for temperatures in the range of 350 to 450°F to bridge the temperature gap between epoxies and other polyimides. They are more expensive and tend to be more brittle than epoxies. Condensation polyimides are used for composite applications from 450 to 520°F. These materials are difficult to process and tend to be quite brittle so their application is limited to adhesive bonding with some structural composite hardware. Combination-reaction polyimides have the highest thermal and oxidative stability and are used at service temperatures to 600°F. These resins are considerably more complicated because of their reaction mechanisms and the handling difficulties of the chemicals. Their application is principally restricted to aerospace composite structures where the performance needs to justify the difficult processing and high cost.

## Processing

Continuous-fiber composites are manufactured in two steps, preform fabrication and consolidation/curing. The material comes in either the dry-fiber (without resin) form or with resin included called *prepreg*. Dry fibers are used in filament winding, pultrusion, weaving, braiding. In the case of filament winding and pultrusion, resin is introduced at the same time fibers are during the time of winding and pultrusion. Resin can also be introduced to the fiber later by resin-transfer molding (RTM). Prepreg, at a higher material cost, eliminates the step of resin addition and provides the adhesion to hold the material together. Layup of prepreg, a time-consuming process, is a common method used in the aerospace industry where complex contoured surfaces are present.

Consolidation and curing consist of compacting the material to remove entrapped air, volatile, and excess resins while developing the structural properties by increasing the polymer chain length and

**FIGURE 12.6.5** A typical curing cycle of epoxy composite with corresponding Rheometric Dynamic Spectroscopy (RDS), Differential Scanning Calorimetry (DSC), and Thermogravimetric Analysis (TGA) curves.

cross-linking. Thermosetting polymer matrices must be cured *in situ* with the fibers to form composites. The goals of a successful cure are good consolidation with low porosity and high conversion of initial monomeric constituents to polymer (degree of cure).

The cure cycle of an epoxy resin composite is shown in Figure 12.6.5. At the start of the cure cycle, the material is normally under vacuum to remove residual volatile. The temperature is then ramped to the point where the polymer is melted. The ramp rates on heating must be slow enough as not to cause unnecessary thermal gradients and to avoid dangerous exotherm (runaway reactions) but not so slow as to cause excessive process time or premature cross-linking. Normal ramp rates are generally in the 1 to 5°F/min range. An isothermal hold of about 30 to 60 min is performed at the point where the resin reaches its minimum in viscosity, during which pressure is applied and the polymer allowed to flow, thus consolidating the laminate. Following consolidation, the temperature is increased to the point where cross-linking occurs (350°F for this example). An additional hold of about 30 to 90 min is performed at this temperature to allow for the material to complete cross-linking. This event is shown as the end of the exothermic peak in the DSC curve as well as the asymptotic high-viscosity region.

Epoxies cure via addition reactions where no volatile is generated during the cross-linking process. However, many other matrix materials (e.g., phenolics and many polyimides) cure via condensation reactions.

### Mechanical Properties

Mechanical properties of polymer composites depend substantially on the processing and fabrication methods used, as well as on the fiber orientation. Thus, standard materials do not exist and it is difficult to generalize regarding properties. The three most significant factors in determining properties are the type of fiber, the volume fraction fiber, and the orientation of the fiber. High-strength high-modulus graphitic carbon fibers will, of course, produce stronger, stiffer composites than those produced from fiberglass. Similarly, 60 vol % fiber composites will be stronger and stiffer than 30 vol %, and uniaxially aligned fiber composites will have maximum properties along the alignment axis, but will be highly

anisotropic and will have poor properties in off-axis orientations. Cross-ply and laminated structures are standard approaches to reducing anisotropy.

Composite stiffness,  $E_c$ , can be approximated for polymer composites by application of the rule of mixtures:

$$E_c = E_f V_f + E_m (1 - V_f)$$

where  $E$  is the modulus of elasticity and  $V$  is the volume fraction fibers. Subscripts  $c$ ,  $f$ , and  $m$  refer to composite, fiber, and matrix, respectively. Similar expressions approximate other properties. Properties of commonly used commodity composite materials are given in Tables 12.6.3 to 12.6.5. Advanced engineering polymer composites have specialized properties which depend on the parameters discussed previously. Expected properties of such advanced polymer composites can only be approximated once the component and material variables are determined during the design stage. The recommended approach is to work with a composite fabricator during the design phase to establish the expected mechanical properties.

*Notes:* Most nylon resins listed in this table are used for injection molding, and test values are determined from standard injection-molded specimens. In these cases a single typical value is listed. Exceptions are MoS<sub>2</sub>-filled nylon and direct-polymerized (castable) nylon, which are sold principally in semifinished stock shapes. Ranges of values listed are based on tests on various forms and sizes produced under varying processing conditions.

Because single values apply only to standard molded specimens, and properties vary in finished parts of different sizes and forms produced by various processes, these values should be used for comparison and preliminary design considerations only. For final design purposes the manufacturer should be consulted for test experience with the form being considered. Listed values should not be used for specification purposes.

## Metal Matrix Composites

### Introduction

The term *metal matrix composites* is usually reserved for fiber-reinforced materials, although technically it applies to particulate-reinforced systems also. The general term for particulate-, whisker-, and chopped-fiber-reinforced systems is *cermet*. A majority of commonly used systems are based upon particulate reinforcements.

### Cermets and Cemented Carbides — Particulate-Reinforced MMCs

The term *cemented carbide* is applied to particulate composites based upon tungsten carbide in a cobalt matrix. This distinction is largely historical, not technical. The tungsten carbide–cobalt-based materials were first developed in Germany, while development of other cermets (including noncarbide-, oxide-, and nitride-based systems) occurred in the United States during and immediately after World War II. Thus, a distinguishing nomenclature was developed both because “carbide” was no longer completely appropriate with oxide systems available and for geopolitical reasons. This nomenclature confusion between the most common cermets, the cemented carbides, and other materials still survives. The structure consists of a continuous metal alloy functioning as cement which holds together particles of carbide, oxide, or nitride ceramic. These materials provide strength, high hardness, wear (abrasion) resistance, low sliding friction, and precise tolerance even at quite high temperatures. Cermets and cemented carbides derive their usefulness when the compressive strength, hardness, and thermal resistance of the ceramic reinforcement is coupled with the ductility, toughness, adhesion, and lubricity provided by the metal. Common applications include metal and rock cutting and grinding tools, high-temperature containers, and pouring spouts, rocket nozzles, turbine parts, flame nozzles, friction and glide parts, seals, magnetron tube cathodes, flame nozzles, and ballpoint pen tips.

A cermet is usually fabricated by mixing the ceramic and metal powders together with a binder incorporated. This often requires high-energy mixing because of density differences with tooling made of the same cermet to avoid contamination. Subsequently, the part is formed, commonly by unidirectional or isostatic pressing, to final shape (accounting for shrinkage) with a wear-resistant die and with the formed object then liquid phase sintered in a controlled-atmosphere furnace. The chemistry is often quite complex in order to control the structure and the interfacial bond between metal and ceramic. Molybdenum promotes wetting of titanium carbide by molten nickel. Tantalum and titanium carbides are usually added to tungsten carbide–cobalt cemented carbides. Some cermets are prepared by slip casting, liquid metal infiltration, hot pressing, or solid-state sintering of parts. In some cases the material is “deficient” in metal to provide porosity for the passage of ink (pen tips) or incorporation of lubricant.

As indicated in the introduction to this section, a good bond between ceramic grain and metal “cement” is required for proper load transfer and to provide a homogeneous structure for good load bearing and uniform deformation. This normally requires a good wetting between liquid metal and ceramic grains. This is affected by minor alloying additions to the metal and the firing atmosphere.

The distribution, stability, and composition of phases have profound effects on properties. The production of WC–6 % Co is a good example of the need for strict compositional control. The tertiary-phase diagram shows that the composition range from 6.00 to 6.12 % must be adhered to in order to prevent formation of phases other than WC and Co — a composition range of less than 0.12 %! Embrittlement by graphite occurs at higher carbon content and by eta phase ( $\eta$ -WC<sub>1-x</sub>) at lower carbon levels. Precise formulation and furnace atmosphere control is required, usually assisted by using a graphite-lined furnace. About 0.1% outside the acceptable composition range there is a drop of about 25% from the optimum strength.

It is important to engineer the microstructure of cermets in order to optimize properties. A uniform dispersion of round oxide, carbide, or nitride grains in the matrix of metal binder is desired. Inhomogeneity and sharp grain corners can act as failure origins. Round grains result from powder preparation and/or partial dissolution of sharp contours in the molten metal. As the amount of binder increases (Figure 12.6.6), the indentation hardness of the composite decreases, because metal, compared with

**FIGURE 12.6.6** Effect of increased binder on strength and hardness of a TiC-Ni-Mo cermet with a 1 μm average carbide particle size.

ceramic, has a lower elastic modulus and will deform more easily. Fracture strength increases with binder because the metal phase confers fracture toughness. Generally, as ceramic grain size decreases, hardness and resistance to deformation increase for a fixed relative amount of ceramic. However, if the surface area increases sufficiently because of small grain size, there may not be sufficient metal to wet all the grain.

With these diverse factors a simplified way of looking at microstructural features and adjusting them for optimum performance is the mean free path, the average distance between neighboring ceramic grains (the average thickness of the binder phase). The mean free path depends on the size and shape of the grains and the amount of metal matrix available. Hardness, elevated-temperature hardness, strength, and toughness depend on the mean free path because it is the zone for absorption of crack energy and the medium for load transfer from grain-to-grain. Figure 12.6.7 shows that hardness varies with mean free path for a variety of cobalt contents and tungsten carbide grain sizes in cemented carbide. The curve does not continue below 0.1 μm because the metal binder becomes discontinuous.

**FIGURE 12.6.7** Effect of mean free path on hardness for a cemented carbide.

### Fiber-Reinforced MMCs

Fiber-reinforced MMCs may still be classed as an emerging materials area. A number of applications have been practiced driven by the need for a lightweight, high-stiffness material and/or for elevated-temperature resistance in structures. These applications are typically for aerospace and similar advanced applications which can use a premium material. The limited scope of current practical application and the limitations placed on technology disclosure by the Export Control Act and International Traffic-in-Arms Regulations make this section brief.

High-strength/high-elastic-modulus fibers such as boron, silicon carbide, graphite, aluminum oxide, and tungsten metal are typically incorporated in light metal matrices such as aluminum, magnesium, and titanium. The specific modulus (elastic modulus divided by density) has been shown to be two to four times that of high-strength structural metals. The specific strength may be substantially higher than the metal. These properties are maintained to many hundreds of degrees above ambient, while those of many advanced structural metals deteriorate both in immediate heating and long-term creep. Some systems have been shown to have considerable fatigue resistance, showing several times the stress for equivalent cycle lifetimes. These properties are important for structural shapes in which light weight and elevated-temperature resistance can afford a premium. Some applications have been struts and tubes

for space structures, bicycle frames, turbine parts, propellers, and engine components. The fiber may be incorporated unidirectionally, as a woven 2D laminate or a 3D structure. Fabrication methods include diffusion bonding, pultrusion (hot isostatic drawing), hot rolling, molten metal infiltration, and casting.

Table 12.6.7 gives metal matrix strengthening values for fiber reinforcements added in volume percentages from 8 to 60%.

## Ceramic Matrix Composites

*Richard L. Lehman and Daniel J. Strange*

CMCs are ceramic matrix materials, either oxide, carbide, nitride, boride, or similar material, reinforced with particulates, whiskers, or continuous fibers. The reinforcing phase may be of any material, but most interest is directed toward ceramic reinforcement media. The following sections address fiber- and whisker-reinforced ceramic composites, the materials which offer the greatest potential for ameliorating the brittleness of ceramics and for developing exceptional mechanical and structural properties.

### Ceramic Matrix Fiber Composites

*Introduction.* Ceramic matrix fiber composites (CMFCs) are the focus of substantial research but of limited commercial application as of this writing. The research enthusiasm is stimulated by the potential of high strength and toughness, mechanical and chemical durability, hardness, and oxidation resistance, all at elevated temperatures in the range 1000 to 1400°C. The limited commercialization, which is principally in military and aerospace applications, stems from the substantial cost of the fabricated materials, often in the range of thousands of dollars per kilogram. Fiber and matrix materials and properties used in CMFCs are presented in Table 12.6.8.

TABLE 12.6.8 Ceramic Matrix Composites: Fiber and Matrix Properties

Material	$E$	$a$	$R$	UTS	$e^*$	$g(Kc)$	$T$	$r$

**Mechanical Behavior.** The primary goal of reinforcing a ceramic material with ceramic fibers is to increase the fracture toughness of otherwise brittle ceramic materials. In a monolithic ceramic, a flaw will propagate through the material under tension due to stress concentration at the crack tip. CMCs are designed with  $E_f/E_m > 1$  so that the reinforcing fiber absorbs stresses which tend to open and propagate cracks. Thus, the stress at the crack tip is reduced. Fiber debonding at the crack front, sliding, crack deflection, and other mechanisms also contribute to toughness. Often this is referred to as “rising R-curve” behavior, indicating that the strength of the ceramic at a crack tip increases with increasing crack length, stopping or slowing further crack growth. The most significant feature of CMFCs is the extensive fiber pullout, which occurs during failure. The fiber pullout results from low interfacial shear strengths,  $\tau$ , which is designed into the composite by modifying interfacial properties and by using fibers with a low Weibull modulus. Loading is characterized by an initial elastic region followed by progressive failure of the matrix. The behavior is illustrated in Figure 12.6.8. During this matrix failure region, monotonically increasing loads are supported by the fibers. Ultimately, the fibers begin to fail according to bundle theory and the remaining load support is provided by the frictional resistance to fiber pullout, a highly significant effect which absorbs large amount of energy and contributes a high strain-to-failure performance previously unknown in ceramics. This “graceful” failure allows for a less catastrophic failure than normally encountered in ceramics and is of great significance in the design of such materials as turbine blades where the consequences of catastrophic failure are severe.

**Continuous and Chopped Fiber Composites.** The use of a continuous fiber reinforcement can have several advantages over the use of chopped fibers. There is a larger strain to pullout due to the increased fiber length, and the continuous fibers do not have stress-concentrating “flaws” as do the exposed ends of chopped fibers. Also, the prearrangement of the fibers allows very careful control of the properties in each direction, and the properties parallel to the fiber orientation will more closely mirror those of the fibers themselves than of the matrix. However, this type of composite is much more difficult to fabricate because of the problems of fiber weaving and forming, resistance to matrix infiltration, and

**FIGURE 12.6.8** Load deflection behavior of CMFCs illustrating regions of fracture behavior.

resistance to densification, which necessitates expensive densification techniques, such as hot pressing, chemical vapor infiltration, polymer pyrolysis, directed metal oxidation, or sol-gel infiltration.

**Glass Matrix CMFCs.** A broad class of CMFCs has been developed and commercialized based on glassy matrix materials. The incentive for using a glassy matrix is the ease with which the matrix can be densified at low temperatures by vitreous sintering as opposed to the high-temperature solid-state sintering required for crystalline matrices. The low-temperature processing, in addition to being lower cost, preserves the high-strength properties of the fibers, which can easily be degraded at high temperatures. Unfortunately, the useful temperature of a glass-based CMC is limited to the  $T_g$  of the matrix, or slightly above, which prohibits traditional glass matrix CMCs from being used in extreme temperature applications (above approximately 1000°C). Newer glass and glass-ceramic compositions in the CaO-Al<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> system are pushing this limit to the region of 1300°C. Two commercial glass matrix composites are Compglas™ and Blackglas™, both glass and glass/ceramic matrix materials reinforced with SiC fibers.

Polycrystalline matrix CMCs achieve higher temperature stability than the glass matrix composites, allow a wider choice of matrix materials, and generally have fewer problems with matrix reactivity. Typical crystalline matrix materials are the SiC, Si<sub>3</sub>N<sub>4</sub>, Al<sub>2</sub>O<sub>3</sub>, ZrO<sub>2</sub>, and mixed silicates. Unfortunately, it is extremely difficult to sinter a CMC with a polycrystalline matrix to full density because of the interference of the fibers. This is particularly true with the nonoxide matrix materials. Pressureless sintering is ineffective for these materials, which necessitates the use of hot pressing or other exotic forming processes which raise material costs considerably.

### Ceramic Matrix Whisker Composites (CMWCs)

Whisker reinforcement of ceramic matrices, while not as exotic, can dramatically increase toughness while preserving relatively inexpensive forming techniques. Figure 12.6.9 illustrates the “rising R-curve” behavior of alumina with the addition of SiC whiskers, while Figure 12.6.10 shows the increase in

fracture strength. The composites can generally be fully densified with hot pressing or hot isostatic pressing (HIP). Unfortunately, the toughness values achieved to date with whisker reinforcement are not as high as those for continuous-fiber reinforcement, although the lower cost of whisker composites has stimulated industrial applications. Cutting tool inserts, which must withstand high stresses at elevated temperatures (1200°C), are fabricated commercially from SiC-whisker-reinforced Al<sub>2</sub>O<sub>3</sub> (SiC/Al<sub>2</sub>O<sub>3</sub>). These composite inserts have been a commercial product for a decade and are an excellent example of cost-effective CMCs, i.e., high-value-added material applied to a small part exposed to extreme conditions. Health concerns regarding highly durable ceramic whiskers produced from SiC or Si<sub>3</sub>N<sub>4</sub> have severely limited development and commercialization of these composites in the United States and Europe.

FIGURE 12.6.9 Fracture toughness and R-curve behavior of ceramic matrix whisker composites.

## Carbon–Carbon Composites

### Introduction

Carbon–carbon composites were originally developed for rocket nose cones in the 1960s because of their high specific strength, fracture toughness, thermal shock, and erosion resistance. Today, carbon–carbon composites are used in a broader range of applications, including brake components, fasteners, heaters, crucibles, and other assorted high-strength/high-temperature products.

### High-Temperature Oxidation

Perhaps the greatest obstacle to the use of carbon–carbon composites as an engineering material, aside from high cost, is low oxidation resistance above 500°C. Although carbon–carbon maintains its mechanical properties to very high temperatures (>2000°C), it must be protected from oxidizing atmospheres at these temperatures or it will quickly degrade. Generally this is accomplished with SiC coatings with varying degrees of success. For most high-temperature oxidizing applications, carbon–carbon composite components are simply replaced when erosion reaches specified limits.

**FIGURE 12.6.10** Strength behavior of SiC whisker-reinforced alumina matrix ceramic composite.

### Fabrication

Most carbon-carbon composites are fabricated by polymer pyrolysis, the process of soaking carbon fiber yarns in a solution of a suitable polymer, then winding or laminating the fibers into the desired shape. Coal tar-based pitches, phenolics, and polyimides are also used as precursors.

The resulting green composite is then pressed, cured, and heated to 800 to 1200°C in an inert atmosphere, carbonizing the precursor. Some structures are heated to 2500°C to graphitize the matrix. The matrix after carbonization will contain a high porosity, typically 30%. This porosity is reduced by infiltrating the matrix with the precursor again and repeating the carbonization cycle. The densification cycle is repeated until the desired density is reached.

Carbon-carbon composites can be formed in random, unidirectional, 2D, 2.5D, and 3D weaves. Unidirectional weaves provide the highest strength along the fiber axis, but much lower strength in other directions. Unidirectional weaves are generally only used in laboratory investigations, as they have little technical value. 2D weaves (fabrics) are by far the most common due to the relative ease of manufacture and good mechanical properties in the plane of the fabric. 2.5D and 3D weaves allow the weaving of very complex structures with good properties in any desired direction, yet the weaving costs can be prohibitive and unnecessary for most industrial applications.

### Mechanical Properties

Properties of some carbon-carbon composite materials are given in [Table 12.6.9](#). The properties can vary considerably, however, depending upon factors such as the weave, tow diameter, precursor, pressing pressure, heat-treatment temperature, and number of densification cycles.

Under cyclical loading, carbon-carbon withstands 70 to 80% of its ultimate tensile strength. Carbon-carbon composites also have large strains to failure, exhibiting pseudoplastic behavior. This is unusual for a high-temperature ceramic material and is one of its prime attractions. The responsibility for this behavior lies with the low fiber-matrix interfacial bond strength and matrix microcracking. Unlike most high-temperature materials, the mechanical properties of carbon-carbon do not degrade at

high temperatures. In fact, in inert atmospheres the strength of carbon–carbon composites increases by 40 to 50% up to a temperature of 1600°C.

Thermal conduction, electrical conduction, and thermal expansion are all much greater along the direction of the weave than perpendicular to it. Interestingly, thermal expansion is negative in 2D weaves perpendicular to the fibers. It is therefore possible to use the fiber architecture to achieve near zero thermal expansion in some directions.

## 12.7 Ceramics and Glass

*Richard L. Lehman, Daniel J. Strange, and William F. Fischer, III*

### Traditional Ceramics

Traditional ceramics encompass many materials, not simply pottery, dinnerware, tile, and sanitaryware, but also technical whitewares, structural clay products, refractories, glazes, and enamels. The product and processing technology of these materials has advanced substantially in recent years which has improved products, reduced costs, and expanded application. Refer to [Table 12.7.1](#) for properties of selected ceramics in this group.

**TABLE 12.7.1 (Part I) Physical Properties of Selected Ceramics**

Dielectric constant	6.0–7.0	4.5–5.5	4.5–6.5	5.0–6.0

### Whitewares

Whitewares are principally comprised of traditional ceramic bodies that are white, cream, ivory, or light gray in appearance. Most whiteware materials are formulated from clay, flint, and feldspar (triaxial compositions) although other additives may be incorporated. The engineering properties of whitewares are strongly affected by porosity, a characteristic that reduces frost resistance and cleanability but is essential for certain aesthetic effects.

*Vitreous.* Vitreous whiteware bodies are translucent and have no open porosity, while earthenware and wall tile, for example, have substantial porosity, and semivitreous bodies bridge the gap in both porosity and translucency. The firing temperature is largely responsible for the differences in properties of the bodies by affecting the degree of vitrification. The general categories of products within the whiteware group are given in [Table 12.7.2](#).

*Earthenware.* Earthenware materials are defined as a nonvitreous clay-based ceramic ware of medium porosity (4 to 20%). They can be glazed or unglazed in their finished form. There are four primary subclasses of earthenware, natural clay, fine, semivitreous, and talc earthenware. Natural clay earthenware is derived from a single, unbeneficiated clay, whereas fine earthenware possesses beneficiated clays, as well as nonplastic materials, to comprise a triaxial body. Semivitreous earthenware is also a triaxial body, but it is fired to a higher temperature to form a more glassy phase, thereby creating a body with

Vitreous china	0.1–0.3	Sanitaryware
Hotel china	0.1–0.3	Tableware
Cookware	1–5	Ovenware and stoveware
Technical china	<0.5	Chemicalware and ball mill jars and media
Fine china	<0.5	Tableware and artware
<b>Porcelains</b>		
Technical porcelains	<0.2	Chemicalware
Triaxial electrical porcelains	<0.2	Low-frequency insulators
High-strength electrical porcelains	<0.2	Low-frequency insulators
Dental porcelains	<0.1	Dental fixtures

the lowest porosity of the earthenware group, usually between 4 and 9%. The final earthenware body is talc earthenware, produced principally from raw talc, with porosity ranging up to 20%. Earthenware bodies range in color from white for the talc and triaxial bodies, to tan and brown for many artware bodies, to a rusty red for terra-cotta.

**Stoneware.** Stoneware bodies can be either vitreous or semivitreous. They are primarily composed of nonrefractory fireclays or a combination of triaxial materials that matches the forming, firing, and finished properties of a natural stoneware body, bodies made from a single, naturally occurring, largely unbeneficiated clay-bearing material. Fine stonewares incorporate beneficiated clays, as well as nonplastics. Jasper stonewares are composed primarily from barium-containing compounds, while basalt stonewares contain large amounts of iron oxide.

Vitreous stoneware bodies are made from blends of a variety of beneficiated materials that are fired to higher temperatures to achieve low porosity levels (0 to 5%) necessary for many applications. Stoneware bodies are usually quite durable and resistant to chipping. However, translucency is less than that of china and the colors are not as white because of the presence of iron and other impurities.

**China and Porcelain.** China and porcelain are nearly synonymous terms which refer to fully vitreous (no porosity) clay, flint, feldspar compositions which are typically glazed, fired to high temperatures, and exhibit strength, hardness, and chemical durability. The term *china* is used to describe exceptionally fine materials prepared from low-impurity raw materials and used in artware and dinnerware. In modern times there has been a trend toward highly vitreous and highly translucent china compositions. Porcelain is used to describe mostly technical ceramics of the triaxial composition which are used as electrical insulators, sanitaryware, and chemical ware.

Subclassifications of china exist, such as vitreous china, hotel china, cookware, technical ceramics, fine chinas, and porcelains. Body formulations are usually based on the triaxial body, clays, flint/silica and fluxing agents, most usually feldspathic materials. However, there are a large number of bodies that are composed of a large fraction of other materials. Inclusive of these are alumina, bone ash, cordierite,

other fluxes, and/or lithium compounds. Vitreous china is a category of traditional ceramics referring to the various sanitaryware plumbing fixtures and accompaniments. Hotel chinas, as the name implies, are generally used in commercial food establishments. Both bodies are glazed in a single firing operation in which both the body and glaze mature at the same time.

Technical whitewares account for a wide variety of vitreous ceramics used in the chemical, dental, refractory, mechanical, electrical, and structural areas. The compositions of most of these materials are similar to that used in the hotel chinas, with the possible substitution of alumina and zircon for some or all of the silica. These materials can be either glazed or unglazed with water absorption less than 0.5%.

Fine china bodies, including bone china, are highly vitrified and translucent materials that are usually fired in two or more separate operations. The first, higher-temperature firing matures the body and a second, lower-temperature firing matures the newly applied glaze. The separate firing conditions allow for the use of high-gloss glazes. Subsequent firings are used to apply decals and metallic decorations.

Porcelain ceramics are mostly used in technical applications. The typical body is triaxial (Table 12.7.2), although some or all of the silica can be replaced with alumina to increase the mechanical properties. Aside from triaxial porcelains, compositions in the  $\text{MgO} \cdot \text{Al}_2\text{O}_3 \cdot \text{SiO}_2$  composition range are popular for electronic applications due to the absence of mobile alkali ions.

## Refractories

*Introduction.* Refractory ceramic materials are by nature inert, high-melting-point compounds that are resistant to corrosion throughout the temperature range of use. Refractories must also withstand thermal cycling, thermal shock, mechanical fatigue, and a range of chemical attack from the elevated-temperature environments typical of most applications. Refractory materials are used in the processing of metals (75% of all refractories), glass, cement, and in the processing of nearly all ceramics.

*Temperature Tolerance.* A quality refractory must be stable at the intended use temperature. Refractoriness is a measure of the highest use temperature the material can withstand and is limited by the softening or melting point of the constituent oxides. Most refractories are a mixture of phases, and, as such, do not display a distinct melting point, but have a range of temperatures where the material starts to soften or melt. Most frequently, a refractory is categorized by an upper use temperature, but sometimes the refractoriness is quantified by the PCE or pyrometric cone equivalent. The PCE is a measure of the heat content that the refractory can withstand before beginning to soften, which is determined by the slumping of pyrometric cones during thermal cycle testing. This value may correspond to different temperatures under different environments or atmospheres and is thus a good indicator of maximum-use conditions. Refractory suppliers can provide PCEs for specific products. Another measure of a refractory quality is the failure under load temperature. The temperature where a refractory sags or deforms is part of all refractory specifications and is related to the amount and composition of the glassy phase within the material.

*Dimensional Stability and Spalling.* Dimensional stability and resistance to spalling are important performance criteria for most refractories. Spalling is the cracking or flaking of the refractory which usually results from thermal cycling, thermal gradients within the refractory, or compression effects due to differing thermal expansion of the different system materials. Spalling reduces the effectiveness and lifetime of the refractory. The dimensional stability of the refractory is also important. Since the refractory is subjected to both heating and cooling cycles, as well as thermal gradients in use, the expansion of the material is very important when choosing a refractory. Large changes in the size of a refractory set up stresses that can reduce the effectiveness of the refractory and may result in its failure.

*Porosity.* Refractory porosity is closely controlled in manufacturing since it leads to a reduction in the mechanical strength of the material and allows for the penetration and chemical attack of liquids or gases to the internal surface of the refractory. However, on the positive side, the presence of internal pores reduces the thermal conductivity of the material and increases fracture toughness,  $K_{IC}$ .

*Fireclay Refractories.* Fireclay refractories are composed of hydrated aluminosilicates with silica content of up to 75% or more with alumina and other minor contents of less than 40%, although alumina-fortified fireclay refractories are made with considerably higher alumina contents. Properties vary greatly over this wide range of compositions — generally, the higher the alumina content, the higher the performance. Fireclay refractories based on kaolin have a high refractoriness and high load resistance. Resistance to chemical attack and thermal conductivity decrease with increasing porosity, whereas spalling resistance increases. Increased alumina content raises the resistance of the material to attack in molten environments. Fireclay refractories are the most widely used refractory and find application in many industries.

*Alumina Refractories.* High-alumina refractories contain 80 to 99% or more aluminum oxide. As with fireclay materials, the higher the alumina content, the higher the refractoriness and the higher the load-bearing capacity. The chemical resistance of alumina refractories is greater than that of the fireclay refractories. Alumina brick is used to replace fireclay brick in more severe applications in the steel industry. Alumina bricks with phosphate bonding are used in the production of aluminum because of their refractoriness and the resistance of the phosphate bonding to chemical attack by the molten aluminum. Mullite ( $3\text{Al}_2\text{O}_3 \cdot 2\text{SiO}_2$ ) refractories are similar to alumina refractories in performance, but are cheaper and more resistant to thermal shock at the expense of some temperature capability.

*Silica.* Silica brick refractories, used in the glassmaking industry, range in composition from almost pure silica to mixtures containing lime, iron oxide, and alumina, depending on the degree of beneficiation of the raw materials. These refractories show a high degree of volume stability below  $650^\circ\text{C}$  ( $1200^\circ\text{F}$ ) and a lower degree of spalling than the fireclay bricks, largely because of the low thermal expansion of the silica.

*Basic Refractories.* Basic refractories are constituted from magnesite ( $\text{MgO}$ ), calcia ( $\text{CaO}$ ), and chrome ( $\text{Cr}_2\text{O}_3$ ) and are used widely in metallurgical industries where basic slags predominate. They are not suitable in acid, or high-silica, environments. Refractories in this group, such as pure magnesite, dolomite ( $\text{CaO-MgO}$ ), and chrome magnesite materials, have high refractoriness, volume stability, and are very resistant to chemical attack. Magnesite refractories have between 80 and 95%  $\text{MgO}$  content, a level at which the refractoriness and resistance to chemical attack is extremely high. Chromite refractories also have excellent chemical resistance in basic environments, with moderate resistance in acidic environments. The chrome content in these refractories ranges between 30 and 45%. Chrome–magnesite refractories are composed of over 60%  $\text{MgO}$ . Compositions and properties of selected basic and high-duty refractories are given in [Table 12.7.3](#).

## Glazes and Enamels

A glaze is a continuous glassy layer that is bonded to the surface of a ceramic. The glaze is typically hard, impervious to moisture, and easily cleaned. An enamel is similar in properties to a glaze, but the substrate is metallic. The surface finish of either can be altered from glossy to matte by varying the composition or the firing conditions. A glaze is usually composed of an aqueous suspension of ceramic particles that is applied to the surface of a material, dried, and fired. During firing, the materials within the glaze react and melt, forming a thin glassy layer on the surface of the ceramic material. Some materials are pre-fired and then the glaze is applied, or, as is becoming more common, the glaze can be fired along with the body. The maturing temperature of most glazes is on the order of  $500$  to  $1500^\circ\text{C}$ , or  $930$  to  $2730^\circ\text{F}$ . Glazes can be either clear, transparent, or opaque. Some glazes are formulated to form crystals within the glaze for a variety of optical effects, such as opalescence.

There are three main types of glazes used. The first of these are the raw glazes. Raw glazes can be further broken down into leaded, leadless, zinc-containing, slip, and porcelain glazes. Lead promotes the processing of the glaze via low viscosity and surface tension and imparts a high refractive index to the finished glaze. However, due to the health hazards associated with free lead, there has been a movement toward lead-free glazes in certain applications. Lead-free glazes require an increase in the

**TABLE 12.7.3 Compositions and Properties of Selected Basic and High-Duty Refractories**

Refractory	Composition	Maximum Use Temperature in O <sub>2</sub>		Thermal Conductivity		
		(°C)	(°F)	100°C/212°F	500°C/930°F	100°C/1830°F
<b>Basic Refractories</b>						
Silica	93–96% SiO <sub>2</sub>	1700	3090	0.8–1.0	1.2–1.4	1.5–1.7
Fireclay	55–80% SiO <sub>2</sub> and 15–45% Al <sub>2</sub> O <sub>3</sub>	1300–1450	1370–2640	0.8–0.9	0.9–1.1	2.4–2.6
Magnesite	80–95% MgO	1800	3270	3.8–9.7	2.7–4.7	2.2–2.6
Chromite	30–45% Cr <sub>2</sub> O <sub>3</sub> , 14–19% MgO, 10–17% Fe <sub>2</sub> O <sub>3</sub> , 15–33% Al <sub>2</sub> O <sub>3</sub>	1700	3090	1.3	1.5	1.7
Chromite– magnesite	60+% Fe <sub>2</sub> O <sub>3</sub> Al <sub>2</sub> O <sub>3</sub>	1800	3270	1.9–3.5	1.2–2.3	1.6
<b>High-Duty Refractory</b>						
Alumina	100% Al <sub>2</sub> O <sub>3</sub>	1950	3540	26	9.4	5.3
Magnesia	100% MgO	2400	4350	31	12	6
Silica	100% SiO <sub>2</sub>	1200	2190	0.8	1.4	1.8
Mullite	72% Al <sub>2</sub> O <sub>3</sub> , 28% SiO <sub>2</sub>	1850	3360	5.3	3.8	3.4

firing temperature of approximately 150°C, from 1030 to around 1190°C. Porcelain glazes mature at temperatures in the same regime as the underlying body from which they get their name. Zinc-containing glazes are similar to porcelain glazes except that they mature at lower temperatures. Slip glazes are used in artware glazing and high-tension electrical insulators. Fritted glazes are in the form of prereacted glass which has been ground to form a powder. Special glazes offer special optical properties in the finished surface. Salt glazes are formed by injecting salts into the firing kiln, with the resulting glaze having a complex pattern of crystalline and glassy phases. Crystalline glazes are often zinc based and produce crystals within the glaze, again for artistic value. Luster glazes form a metallic coating on the glaze.

### Structural Clay Products

Ceramic materials are used in a wide variety of applications in the construction industry, ranging from concrete and cement for buildings and highways, to structural clay materials for use in piping and roofing. For a discussion of concrete materials refer to Section 12.5.

Structural clay products have been used for millennia. Original uses included tile and clay brick for building construction, as well as pipes in water supply and sewer applications. These materials are still used today because of their high compressive strength and imperviousness to water. Structural ceramics are coarse-grained materials with the one exception of ceramic tile. Typical raw material compositions for these bodies are 35 to 55% clay, 25 to 45% filler, usually silica, and 25 to 55% fluxing material. Colors range from white for the kaolinitic clay products, to a buff for the fireclay materials, to red for the illitic materials. Properties vary widely between the different materials. Most concern is placed on the water absorption, which relates to freeze/thaw durability and compressive strength.

## Advanced Ceramics

### Classes of Advanced Ceramics

Advanced ceramic materials are materials which have been engineered to possess exceptional levels of mechanical, optical, thermal, or other property. Most often the materials possess high strength, high stiffness, or are chemically inert. Typical materials contain oxides, nitrides, or carbides which may be monolithic structures or reinforced with various particulate and/or fibrous materials. Refer to Section

12.6 for a detailed discussion of composites. The reinforcement phase usually, but not necessarily, differs from the matrix material. Phases used in designing engineered ceramics are listed in Table 12.7.4 with specific property characteristics as indicated. Advanced ceramic materials are currently much more varied and less standardized than metals, and materials from different manufacturers, or even from different production lots, will have varied properties.

**TABLE 12.7.4 Selected Properties of Crystalline Phases Used in Engineered Ceramics**

Crystalline Phases	Formula	Melting Temperature (C)	Thermal Expansion $\alpha$ (ppm/°C)	Dielectric Constant $\kappa$
Magnesia	MgO	2852	14	5.5
Magnesia spinel	MgO · Al <sub>2</sub> O <sub>3</sub>	2135	8	8.0
Alumina	Al <sub>2</sub> O <sub>3</sub>	2072	9	10.0

Zinc ferrite	ZnO · Fe <sub>2</sub> O <sub>3</sub>	—	—	—

## Structural Ceramics

*Required Properties.* Structural applications involve the use of ceramic materials in load-bearing situations. Material properties required for these conditions include strength over a wide temperature range, often as high as 1400°C, stiffness, creep resistance, resistance to corrosion and oxidation, and, ideally, damage tolerance or toughness. The major difficulty in the use of ceramics for structural applications is their low fracture toughness compared with metals. Conversely, ceramics excel at high-temperature behavior, have low density/weight ratios, high stiffness, and chemical inertness. At the present level of technology, there is a trade-off between high strength and high toughness. To get a high-strength material usually requires a fine-grain-sized ceramic, while a tough ceramic material often has elongated grains or reinforcement phases that are usually quite large.

*Applications.* Existing and potential applications include automotive, biomedical, power generation, heat exchangers, wear materials, aerospace and military applications, cutting tools, and various other technologies. Table 12.7.5 provides the mechanical properties of selected advanced ceramics. The property values listed are guidelines; exact properties are difficult to specify since the exact properties depend largely on processing. Material selection is governed by the environmental conditions of each application.

## Electronic and Magnetic Ceramics

Electronic and magnetic ceramic materials have a variety of useful functions. Alumina, alumina titanate, and aluminum nitride are used as substrate materials, zirconia is used in oxygen sensors, lead zirconate

TABLE 12.7.5 Mechanical Properties of Selected Advanced Ceramic Materials

Material	Composition	Density (g/cc)	Elastic Modulus (GPa)	Fracture Strength (MPa)	Fracture Toughness $K_{IC}$ (MPa · m <sup>0.5</sup> )	Hardness (Vickers)
Alumina	Al <sub>2</sub> O <sub>3</sub>	3.9	380	Up to 400	4–9	2000

<sup>a</sup> Anisotropic.<sup>b</sup> With Co additions.

titanate (PZT) and lead magnesium niobate are common actuator and transducer materials, and barium titanate and related materials are used in capacitors. Ceramic materials are used not only in military and aerospace applications, but also in consumer electronics, computers, automotive and transportation systems, and power generation systems. Electronic/magnetic ceramics are useful as a result of a variety of properties. Refer to [Table 12.7.1](#) for dielectric property data of selected compositions.

### Optical Ceramics

Zirconia and transparent alumina, or sapphire, are often used as high-temperature windows, due to their high melting points, chemical inertness, and high transparency. They are also used as watch crystals, due to their high scratch resistance. Mirrors made from silicon carbide are being evaluated because of the higher strength-to-weight ratio compared with glass materials and the relatively low coefficient of thermal expansion of SiC. Laser crystals are a group of materials which are often based on doped crystals — yttrium aluminum garnet (YAG) is representative, Infrared (IR) transparent windows and shields are used principally in military and aerospace applications to protect IR sensors from damage. Missile nose cones, or radomes, must possess high mechanical strength and be resistant to mechanical erosion and thermal shock. Typical materials include aluminum oxynitride, spinel, zinc sulfide, calcium fluoride, yttria, and sapphire. Refer to [Table 12.7.6](#) for IR absorption ranges of important ceramic materials.

### Effect of Finishing and Machining on Properties

Final finishing of many advanced ceramics is required to obtain the optimum mechanical properties or to meet design tolerances. Since sharp corners act as stress concentrators and are not associated with good design, they are usually machined to a several-millimeter radius if they occur in the as-manufactured product. Other operations include surface grinding, polishing, or lapping operations. Ceramics are very hard materials, which makes final matching machining extremely time-consuming and expensive. Every effort should be made to fabricate components to close to net shape tolerances, or to machine the piece as much as possible prior to final firing.

## Traditional Glasses

### Definition and Introduction

Traditionally, glass is defined as an inorganic product of fusion which has cooled to a rigid state without crystallizing. This broad definition says nothing about the chemistry of the glass but rather refers to the traditional concept of cooling liquid melts below the melting point to form substances which are rigid elastic mechanical solids but which have not crystallized. The historical model for this process is the melting of soda–lime silicate glass by fusing the raw materials at high temperature and cooling quickly to form the well-known window and container glass still in wide use today. Although this definition is still generally valid, processes exist today in which glass is made without fusion. Chemical and physical vapor deposition, and sol–gel processes are examples. Many organic and metallic materials form glasses and are in commercial use today, thus rendering the “inorganic” part of the historical definition inappropriate.

A more applicable definition of glass is an X-ray diffraction amorphous material which exhibits a glass transition. A glass transition is the temperature point at which the amorphous solid exhibits a continuous change in thermodynamic quantities such as heat capacity and expansion coefficient. Because the structure of the glass is frozen before it reaches equilibrium, a glass is metastable with respect to its corresponding crystalline phase. Unlike the crystalline phase, the glass can have a range of physical properties depending upon the rate of cooling (thermal history) and these properties are universally isotropic.

Although glass can be made from an enormous range of polymers, oxides, metals, and inorganic and organic salts, the principle glasses of interest to a mechanical engineer will be glasses with oxide network formers such as SiO<sub>2</sub>, B<sub>2</sub>O<sub>3</sub>, P<sub>2</sub>O<sub>5</sub>. These oxides, among others, are known as glass formers. They are capable of forming the three-dimensional network essential to the existence of the glassy state. Other

TABLE 12.7.6 IR Transmission Limits for Selected Materials

oxides, such as alkalis, alkaline earths, and various transition elements simply serve to modify the basic network to produce varying properties.

The most common glass in use today is the very old soda–lime–silicate glass composition based on the weight composition: 74% SiO<sub>2</sub>, 16% Na<sub>2</sub>O, and 10% CaO. In this composition the silica is the network former, the sodium breaks up the silicate network to permit melting and fabrication at reasonable temperatures, and the calcia provides ionic bonding within the network to provide chemical durability. This composition is used today, with minor variations, for early all container, window, and tableware glass articles.

### Composition/Properties

Traditional glasses are silicate glasses, i.e., glass which contain SiO<sub>2</sub> as the principal network-forming oxide. [Table 12.7.7](#) give compositions for a representative range of commercial glasses, and [Table 12.7.8](#) lists properties for flat glass. All glasses in [Table 12.7.7](#) contain at least 50% SiO<sub>2</sub> and many are quite close to the traditional 74/16/10 composition mentioned above. The types and amount of modifier oxides are determined by the properties required in use. A more specific list of technical glass compositions from Corning, Inc., and identified by Corning glass codes, is given in [Table 12.7.9](#). Principal glass types are discussed in the following sections.

*Pure Silica Glass.* Pure silica glass (fused silica) has excellent thermal, mechanical, chemical, and optical properties. Thermal expansion is  $5.5 \times 10^{-7} \text{ }^\circ\text{C}^{-1}$ , use temperature is above 1000°C, and it has excellent visible and ultraviolet (UV) transmission. However, the melting point is greater than 2000°C, which makes manufacture extremely difficult and expensive. Therefore, fused silica is used primarily for such demanding applications as optical fibers, semiconductor process equipment, UV lamps, optics, and space shuttle windows. If 7 wt% titanium dioxide (TiO<sub>2</sub>) is added, the thermal expansion coefficient is reduced to zero in normal temperature ranges. This glass (ULE, or ultra low expansion) is used in applications which require exceptional dimensional stability. Telescope mirrors are an example.

*High-Silica Glass.* The high melting temperatures needed to produce pure SiO<sub>2</sub> glass can be avoided by first melting a special sodium borosilicate glass which can be formed into the desired shape. This glass (Vycor®) phase separates and after acid leaching results in a high (>96%) silica glass with nearly the same properties as pure vitreous silica.

*Soda Silica.* In order to lower the melting point, a flux is added. The most common flux is sodium oxide (Na<sub>2</sub>O), which makes a low-melting glass that is soluble in water and is called water glass. Dissolved glass is used to seal or bond materials such as low-speed grinding wheels.

*Soda–Lime–Silica.* This is the most common glass and accounts for more than 90% of all the glasses made today. In this glass, lime (CaO) has been added to improve the durability of simple soda–silica glass. Small amounts of other oxides such as alumina (Al<sub>2</sub>O<sub>3</sub>), magnesium oxide (MgO), and potassium oxide (K<sub>2</sub>O) are also added to further enhance the desired properties. The lime is usually obtained from limestone, and the sodium monoxide is obtained from any number of sodium compounds, notably sodium bicarbonate or common baking soda.

*Aluminosilicate Glass.* Aluminosilicate glass is produced by adding up to 20% Al<sub>2</sub>O<sub>3</sub> to soda–lime glass. Aluminosilicate glasses are resistant to thermal shock and high temperatures, and they are not as difficult to produce as silica glass. They find wide use in electronics and in high-temperature laboratory equipment.

*Borosilicate Glass.* In borosilicate glass much of the soda and lime of ordinary glass is replaced by boric oxide. The result is a glass that has a low thermal expansion and is thus resistant to heat and to sudden changes in temperature. The first borosilicate glass was developed by the Corning Glass Works under the trade name Pyrex. Borosilicate glasses are used in laboratory glassware, as well as in home ovenware. Because of their low thermal expansion they are suitable for applications requiring dimensional stability.

Poisson's ratio	0.23
Coefficient of linear expansion, ppm/°C	8.8
Dielectric constant, 1 Mhz	7.1

*Lead Silicates.* Lead silicate glass has a higher index of refraction and also a higher dispersion than soda–lime–silicate glass and thus finds use in optical applications. The high gloss resulting from high Fresnel reflection makes lead glasses of 24 to 35% PbO popular for consumer products in the form of artware and lead crystal glass. Lead glasses of different compositions are used widely in electronic applications since low-melting sealing glasses can be formed with little or no alkali, a constituent which promotes high electrical loss.

### Strength of Glass

*Theoretical Strength.* Glass below the glass transition temperature ( $T_g$ ) is a brittle solid, with failure originating at flaws (scratches, defects, minute compositional differences) which act as stress concentrators. Without flaws of any kind the strength of glass approaches theoretical levels of about 17 GPa ( $2.5 \times 10^6$  psi). Unfortunately, unless glass is processed under the utmost pristine conditions and then immediately coated to prevent surface abrasion by dust or other environmental agents, the glass will contain flaws which decrease the strength by several orders of magnitude from theoretical levels. Synthetic silica glass optical fibers, prepared under meticulous conditions and tested at 77 K, are among the few glass materials which exhibit nearly theoretical strength.

*Nominal and Design Strength.* The exact failure stress for a specific piece of glass will depend upon the configuration and size of the defect at the crack origin. Since these defects vary in size over a wide range, the standard deviation in the strength of glass will also be large. The glass design engineer must allow large safety factors, often 20 to 50%, to account for the statistical variation. For most types of glass a nominal strength of 70 MPa and a design stress of 7 MPa are typical. [Table 12.7.10](#) summarizes strength and variability in the strength of glasses.

*Strengthening and Tempering.* Glass can be substantially strengthened, or tempered, either by rapid cooling or by ion-exchange of the surface to develop compressive stresses. Fast, uniform cooling of glass plates heated to the softening point will introduce surface compressive stresses on the glass (with corresponding tensile stress in the center) which become permanently frozen into place upon cooling to room temperature. These compressive stresses, typically 70 to 200 MPa, will resist externally applied tensile stresses and help to prevent crack propagation. Tempering will increase the strength of glass by as much as three to six times. Tempered glass will shatter violently when it fails as a result of the sudden release of stored elastic energy, although the broken pieces will not be sharp. Generally, only simple shapes can safely be thermally tempered.

Ion-exchange tempering also improves the strength of the glass by introducing surface compression. In the ion-exchange process large ions are “stuffed” into the interstices in the glass structure previously occupied by smaller ions. This is done by immersing the glass in a molten bath of the alkali salt (typically  $\text{KNO}_3$  for a sodium-containing glass) at an elevated temperature. The larger ions will introduce a compressive strain as they force their way into the glass network. The strains obtainable are much higher

than those from thermal tempering, generating stresses as high as 700 MPa, although the surface compressive layer is quite shallow and subject to penetration. Ion-exchanged glasses can be more than 10 to 20 times as strong as normal glass and are used, for example, in aircraft windshields to resist bird impacts.

### Behavior at Elevated Temperatures

Glasses do not have a clearly defined melting temperature. Instead, there is a temperature range where the viscosity of the glass changes smoothly from solid (greater than 10<sup>14</sup> Pa · sec) to liquid (less than 10 Pa · sec). It is useful to define some points on the viscosity–temperature curve to create a clearer

Compiled from several sources.

picture of the viscosity behavior of a glass. The strain point is defined as the temperature at which a glass will release 95% of its stresses within a period of 6 hr. This occurs at a viscosity of approximately  $10^{13.5}$  Pa · sec. The annealing point occurs at  $10^{12}$  Pa · sec a viscosity at which 95% of stresses will be released in 15 min. At  $10^{6.6}$  Pa · sec, the softening point, the glass will deform under its own weight. The working point is defined as  $10^3$  Pa · sec, and is a typical minimum viscosity for machine working during forming. Refer to Table C.12 in the Appendix, Properties of Silicate Glasses. Many properties of glasses are presented in this comprehensive table, including maximum application temperatures (upper working temperature) and viscosity data for most common glasses. Generally, the extreme upper working temperature corresponds to the strain point of the glass. Normal service conditions are typically 50 to 60% of the strain point on the Kelvin temperature scale. Under normal service conditions glass is a brittle, mechanical solid, it possesses no mechanical characteristics of a liquid, and it will not flow. Specific heat and thermal conductivity data are presented in Table 12.7.11. Below the glass transition, glass is not a supercooled liquid, it is a glass. Old windows are not thicker at the bottom because of viscous flow.

### Chemical Durability

Although glass is often considered an extraordinarily inert material, even the most durable glasses undergo some environmental degradation and many glasses are rapidly attacked by strong acid or basic solutions. Corrosive aqueous environments can cause the ions in the glass to be extracted by a leaching process. Chemical durability behavior is difficult to generalize and trial-and-error testing is usually required for each application. The most severe attack is experienced at extreme high and low pH values; neutral pH solutions rarely attack glass at significant rates. Glasses high in  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , and  $\text{CaO}$  are generally most durable. Glasses high in alkali, such as  $\text{Na}_2\text{O}$  or  $\text{K}_2\text{O}$ , are less durable.  $\text{B}_2\text{O}_3$  and  $\text{PbO}$  are intermediate.

A notable form of chemical degradation which occurs under simple, apparently benign, conditions is weathering. Standard soda–lime–silicate window glass can be permanently damaged in a short time (~30 days) if held under high humidity with a means to retain adsorbed moisture on the surface. Such a means

**TABLE 12.7.11 Thermal Properties of Several Glass Types**

Material	Specific Heat			Thermal Conductivity, cal/cm sec°C × 10 <sup>4a</sup>			
	25°C	500°C	1000°C	-100°C	0°C	100°C	400°C

can be a dirt film or perhaps a sheet of newspaper. The moisture ion-exchanges with sodium ions in the glass, which form a high-pH surface film which accelerates the attack on the glass. Pitting and adherent surface deposits can quickly form, making the glass unusable.

For container applications requiring extremely high purity, it is common to use a durable glass such as a borosilicate or to increase the chemical resistance of the glass using surface treatments of SO<sub>2</sub>, SnO<sub>2</sub>, or TiO<sub>2</sub>.

## Optical Properties

Traditional glasses are principally used because they are transparent in the visible region of the spectrum; windows, containers, and precision optics are examples. Although pure silica is highly transmissive over the entire visible spectrum, impurities impart coloration which detract from the performance of some glasses but which can also be used to produce beautiful and useful colored glasses. Table 12.7.12 lists impurity ions and their resulting colors. Iron is the most common impurity, imparting a blue-green-yellow tint depending on the oxidation state. It is possible to neutralize but not bleach impurity colors by “decolorization,” the addition of complementary coloring oxides to produce an overall neutral gray absorption. Traditional glasses do not transmit well in the UV or IR range, with the exception of certain specialty glasses. Pure silica is the best example, enabling high transmission levels (>10%, 2 mm thickness) from 160 nm to 4 μm.

The refractive index of common silicate glasses are in the range of 1.5 to 1.7 and specific values are given in Table C.12 in the Appendix, *Properties of Silicate Glasses*.

## Specialty Glasses

### Non-Silica-Oxide Glasses

Glasses made from B<sub>2</sub>O<sub>3</sub> and P<sub>2</sub>O<sub>3</sub> glass formers rather than SiO<sub>2</sub> possess some special thermal, optical, and chemical properties which make them of interest in certain narrow engineering fields. Borate glasses, often in combination with PbO, are useful solder and sealing glasses for electronic applications; phosphate glasses have special optical properties and are also used as water-soluble chemicals in industry. Tellurite glasses have high refractive indexes and, hence, are used in some demanding refractive optic applications. Glasses based on Bi<sub>2</sub>O<sub>3</sub>, Sb<sub>2</sub>O<sub>3</sub>, TeO<sub>2</sub>, or V<sub>2</sub>O<sub>5</sub> have very low melting points, suggesting their use as low-temperature electrical seals. Boro-aluminates have very high electrical resistivities. Alkaline earth aluminates have excellent IR transmitting properties and make excellent high-temperature

**TABLE 12.7.12 Coloring Additives to Glass**

Color	Additive

Solarization	Cerium, arsenic

lamp seals. Despite their unique properties, non-silica-oxide glasses are costly and make up only a very small percentage of the glass produced annually.

### Chalcogenide Glasses

A class of excellent IR-transmitting glasses, the chalcogenides, are obtained by combining group VI elements with group V and IV elements. Glasses in this group also exhibit photoconductivity and semiconductivity. Applications for these glasses consist of IR-transmitting optical waveguides (to 20 μm), high-performance IR optical applications, and specialty applications which utilize their photoconductivity properties. Most notable of these applications is the photosensitive coating applied to photocopy drums. Purity issues have limited applications in optical fibers as of this writing.

### Heavy Metal Fluoride Glasses

Heavy metal fluoride glasses (HMFG) are an important new (1975) composition group because of their extremely low theoretical optical attenuation (10<sup>-3</sup> dB/km at 3.5 μm), which makes them candidates for repeaterless transoceanic communication links. Unfortunately, this magnitude of transmission has not been obtained in practice because of problems with high oxygen impurities and crystallization. Furthermore, HMFGs are readily attacked by water, and current development efforts are aimed at improving chemical durability. At present, HMFGs are limited to short transmission distance IR optical applications.

### Amorphous Metals

Certain metal compositions can be fabricated as glasses by subjecting streams of the molten metal to extremely rapid quenching rates (10<sup>5</sup> to 10<sup>8</sup>°C/sec). The resulting glasses possess intriguing properties. Strengths approach theoretical limits, and electrical resistivities are greater than their crystalline counterparts yet decrease with temperature. Most importantly, they have extremely low B–H hysteresis curves. For this reason they are used commercially as power transformer core laminations.

### Amorphous Semiconductors

Many elements and compounds which exhibit semiconducting properties in the crystalline state are also semiconductors in the amorphous state. Si, Ge, P, As, CdGe<sub>x</sub>As<sub>2</sub> (x = 0 to 1.2), Si<sub>1-x</sub>H<sub>x</sub> (x = 0.1 to 0.2) are important examples. These materials are used in fabrication of inexpensive vapor deposition fabrication of photovoltaic cells.

## Glass Ceramics

A useful group of materials is made by batching, melting, and forming a product as a glass followed by heat treatment to nucleate and grow crystalline phases from the glass to produce a ceramic with up to 99% crystalline phase content. The microstructure contains crystals of about 1  $\mu\text{m}$  size, a glassy matrix, and no porosity. The processing route is a principal advantage since high-speed glass-forming methods can be used, no porosity exists, the formed shape can be inspected as a transparent glass, and rejects at the forming stage can be recycled.

Glass ceramics are typically stronger than most ceramics as a result of zero porosity, and they are tougher than glass because of the deflection of crack fronts around the crystals. High-temperature properties are generally not good due to the glassy phase and the nature of the process, thus limiting most glass ceramics to low- and intermediate-temperature applications (<1000°C). A wide range of products has been made from glass ceramics, from home cookware to industrial bearings and aerospace radomes.

## 13.1 Introduction

---

*Jay Lee and Robert Shafrik*

Manufacturing is the means by which the technical and industrial capability of a nation is harnessed to transform innovative designs into well-made products that meet customer needs. This activity occurs through the action of an integrated network that links many different participants with the goals of developing, making, and selling useful things.

Manufacturing is the conversion of raw materials into desired end products. The word derives from two Latin roots meaning *hand* and *make*. Manufacturing, in the broad sense, begins during the design phase when judgments are made concerning part geometry, tolerances, material choices, and so on. Manufacturing operations start with manufacturing planning activities and with the acquisition of required resources, such as process equipment and raw materials. The manufacturing function extends throughout a number of activities of design and production to the distribution of the end product and, as necessary, life cycle support. Modern manufacturing operations can be viewed as having six principal components: materials being processed, process equipment (machines), manufacturing methods, equipment calibration and maintenance, skilled workers and technicians, and enabling resources.

There are three distinct categories of manufacturing:

- *Discrete item manufacturing*, which encompasses the many different processes that bestow physical shape and structure to materials as they are fashioned into products. These processes can be grouped into families, known as unit manufacturing processes, which are used throughout manufacturing.
- *Continuous materials processing*, which is characterized by a continuous production of materials for use in other manufacturing processes or products. Typical processes include base metals production, chemical processing, and web handling. Continuous materials processing will not be further discussed in this chapter.
- *Micro- and nano-fabrication*, which refers to the creation of small physical structures with a characteristic scale size of microns (millionths of a meter) or less. This category of manufacturing is essential to the semiconductor and mechatronics industry. It is emerging as very important for the next-generation manufacturing processes.

Manufacturing is a significant component of the U.S. economy. In 1995, 19% of the U.S. gross domestic product resulted from production of durable and nondurable goods; approximately 65% of total U.S. exports were manufactured goods; the manufacturing sector accounted for 95% of industrial research and development spending; and manufacturing industries employed a work force of over 19 million people in 360,000 companies. In the modern economy, success as a global manufacturer requires the development and application of manufacturing processes capable of economically producing high-quality products in an environmentally acceptable manner.

### Modern Manufacturing

Manufacturing technologies address the capabilities to design and to create products, and to manage that overall process. Product quality and reliability, responsiveness to customer demands, increased labor productivity, and efficient use of capital were the primary areas that leading manufacturing companies throughout the world emphasized during the past decade to respond to the challenge of global competitiveness. As a consequence of these trends, leading manufacturing organizations are flexible in management and labor practices, develop and produce virtually defect-free products quickly (supported with global customer service) in response to opportunities, and employ a smaller work force possessing multi-disciplinary skills. These companies have an optimal balance of automated and manual operations.

To meet these challenges, the manufacturing practices must be continually evaluated and strategically employed. In addition, manufacturing firms must cope with design processes (e.g., using customers' requirements and expectations to develop engineering specifications, and then designing components),

production processes (e.g., moving materials, converting materials properties or shapes, assembling products or components, verifying processes results), and business practices (e.g., turning a customer order into a list of required parts, cost accounting, and documentation of procedures). Information technology will play an indispensable role in supporting and enabling the complex practices of manufacturing by providing the mechanisms to facilitate and manage the complexity of manufacturing processes and achieving the integration of manufacturing activities within and among manufacturing enterprises. A skilled, educated work force is also a critical component of a state-of-the-art manufacturing capability. Training and education are essential, not just for new graduates, but for the existing work force.

Manufacturing is evolving from an art or a trade into a science. The authors believe that we must understand manufacturing as a technical discipline. Such knowledge is needed to most effectively apply capabilities, quickly incorporate new developments, and identify the best available solutions to solve problems. The structure of the science of manufacturing is very similar across product lines since the same fundamental functions are performed and the same basic managerial controls are exercised.

## 13.2 Unit Manufacturing and Assembly Processes

---

*Robert E. Schafrik*

There are a bewildering number of manufacturing processes able to impart physical shape and structure to a workpiece. However, if these processes are broken down into their basic elements and then examined for commonality, only a few fundamental processes remain. These are the building blocks, or unit processes, from which even the most complicated manufacturing system is constructed. This section describes these unit processes in sufficient detail that a technically trained person, such as a design engineer serving as a member of an integrated product and process design team comprised of members from other specialties, could become generally knowledgeable regarding the essential aspects of manufacturing processes. Also, the information presented in this section will aid such an individual in pursuing further information from more specialized manufacturing handbooks, publications, and equipment/tool catalogs.

Considering the effect that a manufacturing process has on workpiece configuration and structure, the following five general types of unit manufacturing process can be identified (Altan et al., 1983; NRC, 1995):

*Material removal processes* — Geometry is generated by changing the mass of the incoming material in a controlled and well-defined manner, e.g., milling, turning, electrodischarge machining, and polishing.

*Deformation processes* — The shape of a solid workpiece is altered by plastic deformation without changing its mass or composition, e.g., rolling, forging, and stamping.

*Primary shaping processes* — A well-defined geometry is established by bulk forming material that initially had no shape, e.g., casting, injection molding, die casting, and consolidation of powders.

*Structure-change processes* — The microstructure, properties, or appearance of the workpiece are altered without changing the original shape of the workpiece, e.g., heat treatment and surface hardening.

*Joining and assembly processes* — Smaller objects are put together to achieve a desired geometry, structure, and/or property. There are two general types: (1) consolidation processes which use mechanical, chemical, or thermal energy to bond the objects (e.g., welding and diffusion bonding) and (2) strictly mechanical joining (e.g., riveting, shrink fitting, and conventional assembly).

### Unit Process Selection

Each component being manufactured has a well-defined geometry and a set of requirements that it must meet. These typically include

- Shape and size
- Bill-of-material
- Accuracy and tolerances
- Appearance and surface finish
- Physical (including mechanical) properties
- Production quantity
- Cost of manufacture

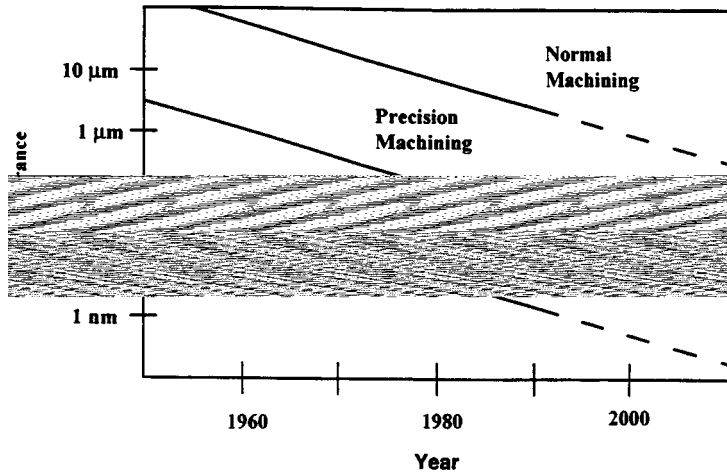

In order to satisfy these criteria, more than one solution is usually possible and trade-off analyses should be conducted to compare the different approaches that could be used to produce a particular part.

### Control and Automation of Unit Processes

Every unit process must be controlled or directed in some way. The need for improved accuracy, speed, and manufacturing productivity has spurred the incorporation of automation into unit processes regarding both the translation of part design details into machine instructions, and the operation of the unit process

itself and as a subsystem of the overall production environment. The section of this chapter on computer-aided design/computer-aided manufacturing (CAD/CAM) discusses the technology involved in creating and storing CAD files and their use in CAM. The expectations of precision are continuing to change, as indicated in Figure 13.2.1. This drive for ever-tighter tolerances is helping spur interest in continual improvements in design and manufacturing processes.

**FIGURE 13.2.1** Precision machining domains. (From NRC, *Unit Manufacturing Processes*, National Academy Press, Washington, D.C., 1995, 169. With permission.)

Modern machine tool controls are emphasizing two areas: adaptive control and communication. For *adaptive control* the controller must adapt its control gains so that the overall system remains at or near the optimal condition in spite of varying process dynamics. Expanded *communication* links the data collected by a unit process controller to other segments of the manufacturing operation. Data regarding production time and quantity of parts produced can be stored in an accessible database for use by inventory control and quality monitoring. This same database can then be used by production schedulers to avoid problems and costs associated with redundant databases.

At the factory level, machining operations employing two or more numerically controlled (NC) machine tools may use a separate mainframe computer that controls several machine tools or an entire shop. The system is often referred to as *distributed numerical control* (DNC).

Today many factories are implementing *flexible manufacturing systems* (FMS), an evolution of DNC. An FMS consists of several NC unit processes (not necessarily only machine tools) which are interconnected by an automated materials handling system and which employ industrial robots for a variety of tasks requiring flexibility, such as loading/unloading the unit process queues. A single computer serves as master controller for the system, and each process may utilize a computer to direct the lower-order tasks. Advantages of FMS include:

- A wide range of parts can be produced with a high degree of automation
- Overall production lead times are shortened and inventory levels reduced
- Productivity of production employees is increased
- Production cost is reduced
- The system can easily adapt to changes in products and production levels

### Unit Processes

In the following discussion, a number of unit processes are discussed, organized by the effect that they have on workpiece configuration and structure. Many of the examples deal with processing of metals

since that is the most likely material which users of this handbook will encounter. However, other materials are readily processed with the unit processes described in this chapter, albeit with suitable modifications or variations.

Mechanical assembly and material handling are also discussed in this section. On average, mechanical assembly accounts for half of the manufacturing time, and processes have been developed to improve the automation and flexibility of this very difficult task. Material handling provides the integrating link between the different processes — material-handling systems ensure that the required material arrives at the proper place at the right time for the various unit processes and assembly operations.

The section ends with a case study that demonstrates how understanding of the different unit processes can be used to make engineering decisions.

- Material removal (machining) processes
  - Traditional machining
    - Drill and reaming
    - Turning and boring
    - Planing and shaping
    - Milling
    - Broaching
    - Grinding
    - Mortality
  - Nontraditional machining
    - Electrical discharge machining
    - Electrical chemical machining
    - Laser beam machining
    - Jet machining (water and abrasive)
    - Ultrasonic machining
- Phase-change processes
  - Green sand casting
  - Investment casting
- Structure-change processes
  - Normalizing steel
  - Laser surface hardening
- Deformation processes
  - Die forging
  - Press-brake forming
- Consolidation processes
  - Polymer composite consolidation
  - Shielded metal-arc welding
- Mechanical assembly
- Material handling
- Case study: Manufacturing and inspection of precision recirculating ballscrews

## Material Removal Processes

These processes, also known as machining, remove material by mechanical, electrical, laser, or chemical means to generate the desired shape and/or surface characteristic. Workpiece materials span the spectrum of metals, ceramics, polymers, and composites, but metals, and particularly iron and steel alloys, are by far the most common. Machining can also improve the tolerances and finish of workpieces previously shaped by other processes, such as forging. Machining is an essential element of many manufacturing systems (ASM, 1989b; Bakerjian, 1992).

Machining is important in manufacturing because

- It is precise. Machining is capable of creating geometric configurations, tolerances, and surface finishes that are often unobtainable by other methods. For example, generally achievable surface roughness for sand casting is 400 to 800  $\mu\text{in.}$  (10 to 20  $\mu\text{m}$ ), for forging 200 to 400  $\mu\text{in.}$  (5 to 10  $\mu\text{m}$ ), and for die casting 80 to 200  $\mu\text{in.}$  (2 to 5  $\mu\text{m}$ ). Ultraprecision machining (i.e., super-finishing, lapping, diamond turning) can produce a surface finish of 0.4  $\mu\text{in.}$  (0.01  $\mu\text{m}$ ) or better. The achievable dimensional accuracy in casting is 1 to 3% (ratio of tolerance to dimension) depending on the thermal expansion coefficient and in metal forming it is 0.05 to 0.30% depending on the elastic stiffness, but in machining the achievable tolerance can be 0.001%.
- It is flexible. The shape of the final machined product is programmed and therefore many different parts can be made on the same machine tool and just about any arbitrary shape can be machined. In machining, the product contour is created by the path, rather than the shape, of the cutter. By contrast, casting, molding, and forming processes require dedicated tools for each product geometry, thus restricting their flexibility.
- It can be economical. Small lots and large quantities of parts can be relatively inexpensively produced if matched to the proper machining process.

The dominating physical mechanism at the tool/workpiece interface in conventional machining is either plastic deformation or controlled fracture of the workpiece. Mechanical forces are imposed on the workpiece by the application of a tool with sharp edges and higher hardness than the workpiece. However, many new materials are either harder than conventional cutting tools or cannot withstand the high cutting forces involved in traditional machining. Nontraditional manufacturing (NTM) processes can produce precision components of these hard and high-strength materials. NTM processes remove material through thermal, chemical, electrochemical, and mechanical (with high impact velocity) interactions.

Machinability is defined in terms of total tool life, power requirements, and resultant workpiece surface finish. To date, no fundamental relationship incorporates these three factors and thus machinability must be empirically determined by testing.

### Process Selection

Machine tools can be grouped into two broad categories:

- Those that generate surfaces of rotation
- Those that generate flat or contoured surfaces by linear motion

Selection of equipment and machining procedures depends largely on these considerations:

- Size of workpiece
- Configuration of workpiece
- Equipment capacity (speed, feed, horsepower range)
- Dimensional accuracy
- Number of operations
- Required surface condition and product quality

For example, Figure 13.2.2 graphically indicates the various tolerance levels that can be typically achieved for common machining unit processes as a function of the size of the workpiece. Such data can help in identifying candidate unit processes that are capable of meeting product requirements.

FIGURE 13.2.2 Tolerance vs. dimensional data for machining processes. (From NRC, *Unit Manufacturing Processes*, National Academy Press, Washington, D.C., 1995, 168. With permission.)

*Traditional Machining*

*Steven Y. Liang*

Traditional machining processes remove material from a workpiece through plastic deformation. The process requires direct mechanical contact between the tool and workpiece and uses relative motion between the tool and the workpiece to develop the shear forces necessary to form machining chips. The tool must be harder than the workpiece to avoid excessive tool wear. The unit processes described here are a representative sample of the types most likely to be encountered. The reference list at the end of

the section should be consulted for more detailed information on the unit processes discussed below, plus those that are not included here.

*Process Kinematics in Traditional Machining.* In all traditional machining processes, the surface is created by providing suitable relative motion between the cutting tool and the workpiece. There are two basic components of relative motion: primary motion and feed motion. Primary motion is the main motion provided by a machine tool to cause relative motion between the tool and workpiece. The feed motion, or the secondary motion, is a motion that, when added to the primary motion, leads to a repeated or continuous chip removal. It usually absorbs a small proportion of the total power required to perform a machining operation. The two motion components often take place simultaneously in orthogonal directions.

The functional definitions of turning, milling, drilling, and grinding are not distinctively different, but machining process specialists have developed terminology peculiar to a given combination of functions or machine configurations. Commonly used metal-cutting machine tools, however, can be divided into three groups depending upon the basic type of cutter used: single-point tools, multipoint tools, or abrasive grits.

*Dynamic Stability and Chatter.* One of the important considerations in selecting a machine tool is its vibrational stability. In metal cutting, there is a possibility for the cutter to move in and out of the workpiece at frequency and amplitude that cause excessive variations of the cutting force, resulting in poor surface quality and reduced life of the cutting tool (Welbourn, 1970).

*Forced vibrations* during cutting are associated with periodic forces resulting from the unbalance of rotating parts, from errors of accuracy in some driving components, or simply from the intermittent engagement of workpiece with multipoint cutters. *Self-excited vibrations* occur under conditions generally associated with an increase in machining rate. These vibrations are often referred to as chatter. All types of chatter are caused by a *feedback loop* within the machine tool structure between the cutting process and the machine frame and drive system. The transfer function of the machine tool, in terms of the stiffness and damping characteristics, plays a critical role in the stability of the overall feedback system. The static stiffness of most machine tools, as measured between the cutting tool and the workpiece, tends to be around  $10^5$  lb-ft/in. A stiffness of  $10^6$  lb-ft/in. is exceptionally good, while stiffness of  $10^4$  lb-ft/in. is poor but perhaps acceptable for low-cost production utilizing small machine tools.

*Basic Machine Tool Components.* Advances in machine-tool design and fabrication philosophy are quickly eliminating the differences between machine types. Fifty years ago, most machine tools performed a single function such as drilling or turning, and operated strictly stand-alone. The addition of automatic turrets, tool-changers, and computerized numerical control (CNC) systems allowed lathes to become *turning centers* and milling machines to become *machining centers*. These multiprocess centers can perform a range of standard machining functions: turning, milling, boring, drilling, and grinding (Green, 1992).

The machine tool *frame* supports all the active and passive components of the tool — spindles, table, and controls. Factors governing the choice of frame materials are: resistance to deformation (hardness), resistance to impact and fracture (toughness), limited expansion under heat (coefficient of thermal expansion), high absorption of vibrations (damping), resistance to shop-floor environment (corrosion resistance), and low cost.

*Guide ways* carry the workpiece table or spindles. Each type of way consists of a *slide* moving along a track in the frame. The slide carries the workpiece table or a spindle. The oldest and simplest way is the *box way*. As a result of its large contact area, it has high stiffness, good damping characteristics, and high resistance to cutting forces and shock loads. Box slides can experience stick-slip motion as a result of the difference between dynamic and static friction coefficients in the ways. This condition introduces positioning and feed motion errors. A *linear way* also consists of a rail and a slide, but it uses a rolling-element bearing, eliminating stick-slip. Linear ways are lighter in weight and operate with less friction,

so they can be positioned faster with less energy. However, they are less robust because of the limited surface contact area.

Slides are moved by hydraulics, rack-and-pinion systems, or screws. *Hydraulic pistons* are the least costly, most powerful, most difficult to maintain, and the least accurate option. Heat buildup often significantly reduces accuracy in these systems. Motor-driven *rack-and-pinion* actuators are easy to maintain and are used for large motion ranges, but they are not very accurate and require a lot of power to operate. Motor-driven screws are the most common actuation method. The screws can either be lead screws or ballscrews, with the former being less expensive and the latter more accurate. The *recirculating ballscrew* has very tight backlash; thus, it is ideal for CNC machine tools since their tool trajectories are essentially continuous. A disadvantage of the ballscrew systems is the effective stiffness due to limited contact area between the balls and the thread. (*Note: a case study at the end of this section discusses the manufacture of precision ballscrews.*)

*Electric motors* are the prime movers for most machine tool functions. They are made in a variety of types to serve three general machine tool needs: spindle power, slide drives, and auxiliary power. Most of them use three-phase AC power supplied at 220 or 440 V. The design challenge with machine tools and motors has been achieving high torque throughout a range of speed settings. In recent years, the operational speed of the spindle has risen significantly. For example, conventional speeds 5 years ago were approximately 1600 rpm. Today, electric motors can turn at 12,000 rpm and higher. Higher speeds cause vibration, which makes use of a mechanical transmission difficult. By virtue of improvement in motor design and control technology, it is now possible to quickly adjust motor speed and torque. Mechanical systems involving more than a three-speed transmission are becoming unnecessary for most high-speed and low-torque machines. Spindle motors are rated by horsepower, which generally ranges from 5 to 150 hp (3.7 to 112 kW) with the average approximately 50 hp (37 kW). Positioning motors are usually designated by torque, which generally ranges from 0.5 to 85 lb-ft (0.2 to 115 Nm).

The *spindle* delivers torque to the cutting tool, so its precision is essential to machine tool operation. The key factors influencing precision are bearing type and placement, lubrication, and cooling.

**Cutting Tool Materials.** The selection of cutting tool materials is one of the key factors in determining the effectiveness of the machining process (ASM, 1989b). During cutting, the tool usually experiences high temperatures, high stresses, rubbing friction, sudden impact, and vibrations. Therefore, the two important issues in the selection of cutting tool materials are hardness and toughness. *Hardness* is defined as the endurance to plastic deformation and wear; hardness at elevated temperatures is especially important. *Toughness* is a measure of resistance to impact and vibrations, which occur frequently in interrupted cutting operations such as milling and boring. Hardness and toughness do not generally increase together, and thus the selection of cutting tool often involves a trade-off between these two characteristics.

Cutting tool materials are continuously being improved. Carbon steels of 0.9 to 1.3% carbon and tool steels with alloying elements such as molybdenum and chromium lose hardness at temperatures above 400°F (200°C) and have largely been replaced by *high-speed steels* (HSS). HSS typically contains 18% tungsten or 8% molybdenum and smaller amounts of cobalt and chromium. HSSs retain hardness up to 1100°F (600°C) and can operate at approximately double the cutting speed with equal life. Both tool steels and HSS are tough and resistive to fracture; therefore, they are ideal for processes involving interrupted engagements and machine tools with low stiffness that are subject to vibration and chatter.

*Powder metallurgy* (P/M) high-speed tool steels are a recent improvement over the conventionally cast HSSs. Powder metallurgy processing produces a very fine microstructure that has a uniform distribution of hard particles. These steels are tougher and have better cutting performance than HSS. Milling cutters are becoming a significant application for these cutting tool materials.

*Cast cobalt* alloys, popularly known as Stellite tools, were introduced in 1915. These alloys have 38 to 53% cobalt, 30 to 33% chromium, and 10 to 20% tungsten. Though comparable in room temperature hardness to HSS tools, cast cobalt alloy tools retain their hardness to a much higher temperature, and they can be used at 25% higher cutting speeds than HSS tools.

*Cemented carbides* offered a four- or fivefold increase in cutting speeds over conventional HSS. They are much harder, but more brittle and less tough. The first widely used cemented carbide was tungsten carbide (WC) cemented in a ductile cobalt binder. Most carbide tools in use now are a variation of the basic WC-Co material. For instance, WC may be present as single crystals or a solid solution mixture of WC-TiC or WC-TiC-TaC. These solid solution mixtures have a greater chemical stability in the cutting of steel. In general, cemented carbides are good for continuous roughing on rigid machines, but should avoid shallow cuts, interrupted cuts, and less rigid machines because of likely chipping.

A thin layer of TiC, TiN, or  $Al_2O_3$  can be applied to HSS or carbide substrate to improve resistance to abrasion, temperature, friction, and chemical attacks. The *coated tools* were introduced in the early 1970s and have gained wide acceptance since. Coated tools have two or three times the wear resistance of the best uncoated tools and offer a 50 to 100% increase in speed for equivalent tool life.

*Ceramic* tools used for machining are based on alumina ( $Al_2O_3$ ) or silicon nitride ( $Si_3N_4$ ). They can be used for high-speed finishing operations and for machining of difficult-to-machine advanced materials, such as superalloys (Komanduri and Samanta, 1989). The alumina-based materials contain particles of titanium carbide, zirconia, or silicon carbide whiskers to improve hardness and/or toughness. These materials are a major improvement over the older ceramic tools. Silicon nitride-based materials have excellent high-temperature mechanical properties and resistance to oxidation. These materials also have high thermal shock resistance, and thus can be used with cutting fluids to produce better surface finishes than the alumina tools.

These tools can be operated at two to three times the cutting speeds of tungsten carbide, usually require no coolant, and have about the same tool life at higher speeds as tungsten carbide does at lower speeds. However, ceramics lack toughness; therefore, interrupted cuts and intermittent application of coolants can lead to premature tool failure due to poor mechanical and thermal shock resistance.

*Cermets* are titanium carbide (TiC) or titanium carbonitride particles embedded in a nickel or nickel/molybdenum binder. These materials, produced by the powder metallurgy process, can be considered as a type of cemented carbide. They are somewhat more wear resistant, and thus can be used for higher cutting speeds. They also can be used for machining of ferrous materials without requiring a protective coating.

*Cubic boron nitride* (CBN) is the hardest material at present available except for diamond. Its cost is somewhat higher than either carbide or ceramic tools but it can cut about five times as fast as carbide and can hold hardness up to 200°C. It is chemically very stable and can be used to machine ferrous materials.

Industrial *diamonds* are now available in the form of polycrystalline compacts for the machining of metals and plastics with greatly reduced cutting force, high hardness, good thermal conductivity, small cutting-edge radius, and low friction. Recently, diamond-coated tools are becoming available that promise longer-life cutting edges. Shortcomings with diamond tools are brittleness, cost, and the tendency to interact chemically with workpiece materials that form carbides, such as carbon steel, titanium, and nickel.

*Wear of Cutting Tool Materials.* Cutting tools are subjected to large forces under conditions of high temperature and stress. There are many mechanisms that cause wear.

- Adhesion. The tool and chip can weld together; wear occurs as the welded joint fractures and removes part of the tool material, such as along a tool cutting edge.
- Abrasion. Small particles on the wear surface can be deformed and broken away by mechanical action due to the high localized contact stresses; these particles then abrade the cutting tool. Typically, this is the most common wear mode.
- Brittle fracture. Catastrophic failure of the tool can occur if the tool is overloaded by an excessive depth of cut and/or feed rate.
- Diffusion. Solid-state diffusion can occur between the tool and the workpiece at high temperatures and contact pressures, typically at an area on the tool tip that corresponds to the location of

maximum temperature, e.g., cemented carbide tools used to machine steel. High-speed machining results in higher chip temperatures, making this an increasingly important wear mode.

- Edge chipping.
- Electrochemical. In the presence of a cutting fluid, an electrochemical reaction can occur between the tool and the workpiece, resulting in the loss of a small amount of tool material in every chip.
- Fatigue.
- Plastic deformation.

*Single-Point Cutting Tool Geometry.* Figure 13.2.3 depicts the location of various angles of interest on a single-point cutting tool. The most significant angle is the *cutting-edge* angle, which directly affects the shear angle in the chip formation process, and therefore greatly influences tool force, power requirements, and temperature of the tool/workpiece interface (ASM, 1989a). The larger the positive value of the cutting-edge angle, the lower the force, but the greater the load on the cutting tool. For machining higher-strength materials, negative rake angles are used. *Back rake* usually controls the direction of chip flow and is of less importance than the side rake. Zero back rake makes the tool spiral more tightly, whereas a positive back rake stretches the spiral into a longer helix. *Side rake* angle controls the thickness of the tool behind the cutting edge. A thick tool associated with a small rake angle provides maximum strength, but the small angle produces higher cutting forces than a larger angle; the large angle requires less motor horsepower.

**FIGURE 13.2.3** Standard nomenclature for single-point cutting tool angles. (From *ASM Handbook, Machining*, Vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 141. With permission.)

The *end relief angle* provides clearance between the tool and the finished surface of the work. Wear reduces the angle. If the angle is too small, the tool rubs on the surface of the workpiece and mars the finish. If the angle is too large, the tool may dig into the workpiece and chatter, or show weakness and fail through chipping. The *side relief angle* provides clearance between the cut surface of the work and the flank of the tool. Tool wear reduces the effective portion of the angle closest to the workpiece. If this angle is too small, the cutter rubs and heats. If the angle is too large, the cutting edge is weak and the tool may dig into the workpiece. The *end cutting-edge angle* provides clearance between the cutter and the finished surface of the work. An angle too close to zero may cause chatter with heavy feeds, but for a smooth finish the angle on light finishing cuts should be small.

**Machinability.** Optimum speed and feed for machining depend on workpiece material, tool material, characteristics of the cut, cutting tool configuration, rigidity of setup, tolerance, and cutting fluid. Consequently, it is not possible to recommend universally applicable speeds and feeds.

## Drilling and Reaming

**Description and Applications.** *Drilling* is the most widely used process for making circular holes of moderate accuracy. It is often a preliminary step to other processes such as tapping, boring, or reaming. *Reaming* is used to improve the accuracy of a hole while increasing its diameter. Holes to be reamed are drilled undersize.

**Key System Components.** Drills are classified by the material from which they are made, method of manufacture, length, shape, number and type of helix or flute, shank, point characteristics, and size series (Table 13.2.1). Selection of drill depends on several factors (ASM, 1989b):

**TABLE 13.2.1 Common Drill Types**

Drill Type	Description	Application
Core	Has large clearance for chips	Roughing cuts; enlarging holes
General-purpose (jobber)	Conventional two-flute design; right-hand (standard) or left-hand helix. Available with flute modification to break up long chips	General-purpose use, wide range of sizes
Gun	Drill body has a tube for cutting fluid; drill has two cutting edges on one side and counter-balancing wear pads on the other side	Drill high-production quantities of holes without a subsequent finishing operation
High helix	Wide flutes and narrow lands to provide a large bearing surface	Soft materials, deep holes, high feed rates
Low helix	Deep flutes facilitate chip removal	Soft materials, shallow holes
Oil hole	Has holes through the drill body for pressurized fluid	Hard materials, deep holes, high feed rate
Screw-machine	Short length, short flutes, extremely rigid	Hard materials; nonflat surfaces
Step	Two or more drill diameters along the drill axis	Produce multiple-diameter holes, such as for drilling/countersinking
Straight flute	Flutes parallel to the drill axis minimize torquing of the workpiece	Soft materials; thin sheets

- Hardness and composition of the workpiece, with hardness being more important
- Rigidity of the tooling
- Hole dimensions
- Type of drilling machine
- Drill application — originating or enlarging holes
- Tolerances
- Cost

The most widely used drill is the general-purpose twist drill, which has many variations. The flutes on a twist drill are helical and are not designed for cutting but for removing chips from the hole. Typical twist drills are shown in Figure 13.2.4.

Machining forces during *reaming* operations are less than those of drilling, and hence reamers require less toughness than drills and often are more fragile. The reaming operation requires maximum rigidity in the machine, reamer, and workpiece.

Most *reamers* have two or more flutes, either parallel to the tool axis or in a helix, which provide teeth for cutting and grooves for chip removal. The selection of the number of flutes is critical: a reamer with too many flutes may become clogged with chips, while a reamer with too few flutes is likely to chatter (Table 13.2.2).

**FIGURE 13.2.4** Design features of a typical straight-shank twist drill. (From *ASM Handbook, Machining*, Vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 218. With permission.)

**TABLE 13.2.2 Common Reamer Types**

Reamer Type	Description	Application
Adjustable	Tool holder allows adjustment of the reamer diameter to compensate for tool wear, etc.	High-rate production
End-cutting	Cutting edges are at right angles to the tool axis	Finish blind holes, correct deviations in through-holes
Floating blade	Replaceable and adjustable cutting edges to maintain tight tolerances	High-speed production (workpiece rotated, tool stationary)
Gun	Hollow shank with a cutting edge (e.g., carbide) fastened to the end and cutting fluid fed through the stem	High-speed production (workpiece rotated, tool stationary)
Shell	Two-piece assemblies, mounted on arbors, can be adjusted to compensate for wear	Used for finishing operations (workpiece rotated, tool stationary)
Spiral flute	Flutes in a helix pattern, otherwise same as straight-flute reamer	Difficult to ream materials, and holes with irregularities
Straight flute	Flutes parallel to the tool axis, typically pointed with a 45° chamfer	General-purpose, solid reamer

*Machining Parameters.* The optimal speed and feed for drilling depend on workpiece material, tool material, depth of hole, design of drill, rigidity of setup, tolerance, and cutting fluid. For *reaming* operations, hardness of the workpiece has the greatest effect on machinability. Other significant factors include hole diameter, hole configuration (e.g., hole having keyways or other irregularities), hole length, amount of stock removed, type of fixturing, accuracy and finish requirements, size of production run, and cost. Most reamers are more easily damaged than drills; therefore, the practice is to ream a hole at no more than two thirds of the speed at which it was drilled.

*Capabilities and Process Limitations.* Most drilled holes are 1/8 to 1 in. (3.2 to 40 mm) in diameter. However, drills are available for holes as small as 0.001 in. (0.03 mm) (microdrilling), and special drills are available as large as 6 in. (150 mm) in diameter. The range of length-to-diameter (L/D) of holes that can be successfully drilled depends on the method of driving the drill and the straightness requirements. In the simplest form of drilling in which a rotating twist drill is fed into a fixed workpiece, best results are obtained when L/D is <3. But by using special tools, equipment, and techniques, straight holes can be drilled with L/D = 8 or somewhat greater. Nonconventional machining processes can also generate high-aspect-ratio holes in a wide variety of materials.

Reaming and boring are related operations. Hole diameter and length, amount of material to be removed, and required tolerance all influence which process would be most efficient for a given application (ASM, 1989b). Most holes reamed are within the size range of 1/8 to 1 inch (3.2 to 40 mm), although larger and smaller holes have been successfully reamed. For most applications with standard reamers, the length of a hole that can be reamed to required accuracy ranges from slightly longer to much shorter than the cutting edges of the reamer, but there are many exceptions to this general rule-of-thumb. Tolerances of 0.001 to 0.003 in. (0.03 to 0.08 mm) with respect to the diameter are readily

achievable in production reaming operations. Surface finish for annealed steels can be held within the range of 100 to 125  $\mu\text{in.}$  (2.50 to 3.20  $\mu\text{m}$ ), but a surface as smooth as 40  $\mu\text{in.}$  (1  $\mu\text{m}$ ) can be obtained under appropriate processing conditions (ASM, 1989b).

### Turning and Boring

*Description and Applications.* *Turning* produces external cylindrical surfaces by removing material from a rotating workpiece, usually with a single-point cutting tool in a lathe. *Boring* is this same process applied for enlarging or finishing internal surfaces of revolution.

*Key System Components.* The basic equipment for turning is an *engine lathe* that consists of a bed, a headstock, a carriage slide, a cross slide, a tool holder mounted on the cross slide, and a source of power for rotating the workpiece (Table 13.2.3). Engine lathes are often modified to perform additional types of machining operations through the use of attachments. Most turning machines can also perform boring operations, but boring machines may not be able to perform turning operations. Sizes of lathes range from fractional horsepower to greater than 200 hp.

**TABLE 13.2.3 Typical Lathes Used for Turning**

Lathe	Description	Applications
Bench lathe	An engine lathe that can be placed on a workbench	Small workpieces and prototype parts
Engine lathe	Has a leadscrew that moves the slide uniformly along the bed; available with chucking or centering headstock	Chucking type allows centering and clamping for rotation, e.g., holding castings or forgings Centering type secures workpiece between pointed centers, e.g., for turning long workpieces, such as shafts
Gap-frame lathe	Modified engine lathe for turning larger diameter parts	Workpieces requiring off-center mounting or irregular protuberances
Numerically controlled lathe	Uses a computer program to control the lathe to generate the desired shape	Produces consistent parts in a CAD/CAM environment
Tracer-controlled lathe	A duplicating lathe that uses a stylus moving over a template to control the cutting tool	Manufacture of prototype parts and low-rate production

**TABLE 13.2.4 Typical Machines Used for Boring**

Boring Machine	Description	Applications
Bar (screw) machine	Modified turret lathe to handle bars and tubes	Parts made from bars or tubes
Engine lathe	Versatile machine; essentially same machine as used for turning	Bores one hole at a time in a single part; limitations regarding workpiece size and configuration
Horizontal boring mill	Workpiece remains stationary and tool rotates	Wide variety of parts; cost-effective for a relatively high production volume
Precision boring machine	Vertical and horizontal models	Parts requiring extreme tolerances
Special-purpose machines	Boring machine modified for specialized application	Single-purpose applications with high production rates
Turret lathe	Has rotating turret on a lathe, tooled for multiple machining operations	More versatile than engine lathe; supports high production rates
Vertical boring mill	Same basic components as a lathe	Very large, heavy, or eccentric workpieces
Vertical turret lathe	Same features as vertical boring mill; may also have a second vertical head	Flexible machine, useful in CAD/CAM environment; simultaneous multiple machining operations possible

Machines used for boring are noted for their rigidity, adaptability, and ability to maintain a high degree of accuracy (Table 13.2.4). For extremely large workpieces, weighing thousands of pounds, the boring cutting tool is rotated and the workpiece is fixed.

*Machine Tool and Machining Parameters.* In turning and boring operations, a single-point tool is traversed longitudinally along the axisymmetric workpiece axis parallel to the spindle. A tangential force is generated when the cutting tool engages the rotating work. This force is generally independent of the cutting speed and directly proportional to the depth of cut for a particular material, tool shape (particularly side rake angle), and feed rate. That force, when multiplied by the surface speed of the workpiece, estimates the net horsepower required to remove material. The extent to which workpiece material affects required machining power is illustrated in Figure 13.2.5. Moving the tool longitudinally requires much less power (ASM, 1989b).

**FIGURE 13.2.5** Effect of workpiece composition and hardness on power required for turning. (From *ASM Handbook, Machining*, Vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 136. With permission.)

To minimize the number of cuts required, the depth of cut should be as great as possible, which is limited by the strength of the part and the fixturing, and the power output of the machine tool. The feed rate is a function of the finish desired and the strength and rigidity of the part and machine tool.

*Capabilities and Limitations.* Components that range in size from those used in watches up to large steel propeller shafts more than 80 ft (24 m) long are regularly turned. Aluminum parts over 10 ft (3 m) in diameter have been turned. In practice, the weight of the workpiece per unit of volume determines the size of the workpiece that is practical to turn. Large, heavy parts can be turned in a vertical boring machine. Irregular-shaped parts, such as crankshafts, may require the use of counter-weighting to achieve dynamic balance for vibration-free turning.

For both turning and boring, the rotation speed, feed, and depth of cut determine the rate of material removal and resulting surface quality. Feed rate for most applications falls between 0.005 and 0.020 in./rev (0.13 and 0.51 mm/rev). Finishing cuts have a significantly lower feed rate (e.g., 0.001 in./rev, 0.03 mm/rev), and roughing cuts are made at a significantly higher feed rate (e.g., 0.25 in./rev, 6.35 mm/rev). Boring is not limited by the L/D ratio of a hole — this ratio can be as great as 50 if the tool bar and workpiece are adequately supported.

There are many potential sources of tolerance error in turning and boring operations. The more common errors are summarized in [Tables 13.2.5](#) and [13.2.6](#).

**TABLE 13.2.5 Factors Affecting Dimensional Accuracy in Turning**

Quantity	Basic Cause of Inaccuracy	Corrective Actions
Diametrical roundness	Lathe spindle runout	Preload angular bearings to eliminate side and end movement
Diameter variation (taper)	Parallelism of spindle to longitudinal travel	Establish true parallelism between the axis of rotation of the workpiece and the longitudinal travel of the cutting tool
Face flatness	Lack of true normality of cross slide to axis of rotation	Precision align cross slide to axis of rotation
Length dimensions parallel to the axis of rotation	Improper positioning of longitudinal slide	Adjust positioning of longitudinal slide
Diameter accuracy	Inadequate gauging	Employ proper measurement technique

**TABLE 13.2.6 Factors Affecting Dimensional Accuracy in Boring**

Quantity	Basic Cause of Inaccuracy	Corrective Actions
Diameter accuracy	Inadequate gauging, or heat generated by the machining action	Employ proper measurement techniques; use cutting fluid to control temperature
Taper of the cylindrical bore	Deflection of the boring bar	Reduce the boring bar unsupported length; use a higher-stiffness material for the boring bar
Roundness, as determined by the variation in radius about a fixed axis	Finish cut is not concentric with the previous cut; or out-of-balance workpiece or holder	Begin with a semifinish cut, followed by a finish cut; carefully balance the initial setup
Concentricity of one surface with another	Too great a clamping force on the workpiece	Redesign clamping fixture, or use a precision boring machine
Squareness and parallelism of holes in relation to other features of the work	Dimensional changes in machine components	Maintain constant ambient temperature; maintain cutting fluid at constant temperature; or stabilize oil temperature

## Planing and Shaping

*Description and Applications.* *Planing* is a widely used process for producing flat, straight surfaces on large workpieces. A variety of contour operations and slots can be generated by use of special attachments. It is often possible to machine a few parts quicker by planing than by any other method. *Shaping* is a process for machining flat and contour surfaces, including grooves and slots.

*Principle of Operation.* *Planers* develop cutting action from straight-line reciprocating motion between one or more single-point tools and the workpiece; the work is reciprocated longitudinally while the tools

are fed sideways into the work. Planer tables are reciprocated by either mechanical or hydraulic drives, with mechanical drives predominating.

*Shapers* use a single-point tool that is supported by a ram which reciprocates the tool in a linear motion against the workpiece. The workpiece rests on a flat bed and the cutting tool is driven toward it in small increments by ram strokes. Shapers are available with mechanical and hydraulic drives, with mechanical drives predominating.

*Machine Tool and Machining Parameters.* Planing and shaping are rugged machining operations during which the workpiece is subjected to significant cutting forces. These operations require high clamping forces to secure the workpiece to the machine bed.

In general, it is advisable to plane steel with as heavy a feed and as high a speed as possible to promote good chip-formation conditions so that chip breakers are not needed. Carbide cutters allow cutting speed to be increased from 225 to 300 surface feet per minute (sfm) (70 to 90 m/min). For best results, uniform cutting speed and feed are maintained throughout the entire stroke (ASM, 1989b).

In general, speeds are related to workpiece material characteristics and associated machinability. Feeds are influenced by the workpiece machinability, but also by ram speed, depth of cut, and required dimensional accuracy and surface finish. Common practice in shaping is to make roughing cuts at as high a feed and slow a speed as practical, and make finishing cuts at a low feed rate and high speed (ASM, 1989b). For low carbon steel, a typical speed for a roughing cut is 50 sfm (15 m/min), while for a finishing cut it is 80 sfm (25 m/min) using a conventional cutting tool. Similarly for aluminum, a roughing cut of 150 sfm (45 m/min) is typically followed by a finishing cut of 200 sfm (60 m/min).

There is a practical lower bound on minimum feed rate. Feed rates that are too low will cause the tool to chatter; feed rates less than 0.005 in. (0.125 mm) are seldom used in shaping. Similarly, shallow cuts (less than 0.015 in., 0.38 mm) will cause chatter during shaping.

*Key System Components.* Planers are available in a wide range of sizes (Table 13.2.7). Tools are available in a variety of configurations for undercutting, slotting, and straight planing of either horizontal or vertical surfaces (ASM, 1989b).

**TABLE 13.2.7** Types of Planers

Planer Type	Description	Application
Double housing	Two vertical uprights support the crossrail which in turn supports the tools	Rigid machine; restricts the width of workpiece
Open side	A single upright column supports a cantilevered crossrail; less rigid than the double-housing type	Accommodates wide workpieces which can overhang one side of the table without interfering with the planer operation

Shapers are available in a large variety of sizes (Table 13.2.8), ranging from small models with a maximum stroke length of less than 6 in. (150 mm) to large machines with a maximum stroke of 36 in. (914 mm). On each machine, the length of stroke can be varied from its maximum to slightly less than 1 in. (25 mm) for the largest machine, and to 1/8 in. (3.2 mm) for the smallest machine.

**TABLE 13.2.8** Types of Shapers

Shaper Type	Description	Application
Horizontal	The ram drives the tool in the horizontal direction; uses plane or universal table (rotates on three axes)	Gears, splined shafts, racks, and so on; not used for rate production
Vertical	The ram operates vertically, cutting on the downstroke	Slots, grooves, keyways; matching die sets, molds, fixtures; not used for rate production

*Capabilities and Process Limitations.* Planing is a precision process in which flatness can be held within 0.0005 in. (0.013 mm) total indicated runout (TIR) on workpieces up to 4 ft<sup>2</sup> (0.4 m<sup>2</sup>). Although planing is most widely used for machining large areas, it is also used for machining smaller parts, although 12 in. is about the minimum distance for a planing stroke. Size of the workpiece that can be planed is limited by the capacity of the planing equipment.

Shaping is a versatile process in which setup time is short and relatively inexpensive tools can be used. Under good conditions, a shaper can machine a square surface of 18 in. on a side (0.2 m<sup>2</sup>) to a flatness within 0.001 in. (0.025 mm); under optimum conditions this can be improved to 0.0005 in. (0.013 mm). The size of the workpiece that can be shaped is limited by the length of the stroke, which is usually about 36 in. (914 mm). Shaping should be considered for machining flat surfaces in these instances:

- Required flatness cannot be achieved by another method
- Production quantity is insufficient to justify the tooling costs of milling or broaching

Planing and shaping are interrupted cutting processes, and are comparatively inefficient means of metal removal; for example, shaping costs five times that of milling, exclusive of the tooling and setup costs.

## Milling

*Description and Applications.* Milling is a versatile, efficient process for metal removal. It is used to generate planar and contour surfaces through the action of rotating multiple-tooth cutters. Surfaces having almost any orientation can be machined because both the workpiece and cutter can move in more than one direction at the same time.

*Principle of Operation.* Cutters with multiple cutting edges rotate in a spindle. The machining process is interrupted as the teeth of the milling cutter alternately engage and disengage from the workpiece.

*Key System Components.* Most milling is done in machines designed for milling (Table 13.2.9). Milling can also be done by any machine tool that can rigidly hold and rotate a cutter while feeding a workpiece into the cutter. Milling machines are usually classified in terms of their appearance: knee-and-column, bed-type, planar-type, and special purpose. The knee-and-column configuration is the simplest milling machine design. The workpiece is fixed to a bed on the knee and the tool spindle is mounted on a column, as depicted in Figure 13.2.6. For very large workpieces, gantry or bridge-type milling machines are used. Machines having two columns can provide greater stability to the cutting spindle(s). Special-purpose machines are modifications of the three basic models.

The usual power range for knee-and-column machines is 1 to 50 hp (0.75 to 37 kW). Bed-type machines are available in a wide range of sizes, up to 300 hp (225 kW). Planar-type machines are available from 30 to 100 hp (22 to 75 kW).

There is a wide variety of milling cutters, using the full range of cutting tool materials; there are three basic constructions (ASM, 1989b):

- Solid — Made from a single piece of HSS or carbide; cutters can be tipped with a harder material; teeth can be designed for specific cutting conditions; low initial cost.
- Inserted blade — Usually made from HSS, carbide, or cast alloy; individual blades can be replaced as they wear out, saving replacement cost; ideal for close-tolerance finishing.
- Indexable insert — Cutter inserts are made from carbide, coated carbide, ceramic, or ultrahard material such as diamond; each insert has one or more cutting edges; as inserts wear, they are repositioned to expose new cutting surface or indexed to bring another cutting insert on line. These inserts, widely used in computer-controlled machines due to their performance and flexibility, can produce a rougher surface than the other tool constructions and require somewhat higher cutting forces to remove metal.

**TABLE 13.2.9** Types of Milling Machines

Milling Machine	Description	Application
Knee-and-column	Six basic components: <ul style="list-style-type: none"> <li>• Base — the primary support</li> <li>• Column — houses spindle and drive</li> <li>• Overarm — provides support for the arbor-mounted cutting tools</li> <li>• Knee — supports the table, saddle, and workpiece; provides vertical movement</li> <li>• Saddle — provides 1° of horizontal motion</li> <li>• Table — directly supports the workpiece and provides a second degree of horizontal motion</li> </ul>	Widely used for low production milling; provides three-axis movement; primary drawback is lack of rigidity due to the number of joints
Bed-type	Table and saddle mounted on a bed in fixed vertical position; vertical motion obtained by movement of the spindle carrier; available with horizontal or vertical spindle	Very rigid machine; permits deep machining cuts and close dimensional control
Planar-type (adjustable rail)	Can accommodate almost any type of spindle for driving cutters and boring bars; utilizes several milling heads	Use for mass-production milling; can perform simultaneous milling and boring operations
Special purpose	Many possible configurations involving major modifications or combinations of the basic types of milling machines; adapted for automated control	Optimized for high-volume production; includes profilers and machining centers; these machines are capable of performing multiple simultaneous machining operations

**FIGURE 13.2.6** Principal components of a plain knee-and-column milling machine with a horizontal spindle. (From *ASM Handbook, Machining*, Vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 304. With permission.)

Milling cutters are also described by the location of the cutting edges, as described in [Table 13.2.10](#). Several cutters are depicted in [Figure 13.2.7](#).

*Machine Tool and Machining Parameters.* The angular relationships of the cutting edge greatly influence cutting efficiency, analogous to single-point cutting tools. A milling cutter should have enough teeth to ensure uninterrupted contact with the workpiece, yet not so many so as to provide too little space between the teeth to make chip removal difficult.

Milling speed varies greatly depending on workpiece material composition, speed, feed, tool material, tool design, and cutting fluid. Speeds as low as 20 sfm (6.1 m/min) are employed for milling low machinability alloys, while speeds as high as 20,000 sfm (6100 m/min) have been reported for milling aluminum (ASM, 1989b). If the setup is sufficiently rigid, carbide or carbide-tipped cutters can be operated three to ten times faster than HSS cutters; top speed is usually constrained by onset of tool chatter.

**TABLE 13.2.10** Types of Milling Cutters

Milling Cutters	Description	Application
Peripheral mills	Cutting is primarily done by teeth on the periphery of the cutting tool; mounted on an arbor having its axis parallel to the machined surface	Removing metal from simple flat surfaces; milling contoured surfaces and surfaces having two or more angles or complex forms
Face mills	Machining action is accomplished by the bevel cutting edge located along the circumference of the mill; driven by a spindle on an axis perpendicular to the surfaced being milled	Can be more efficient at removing material than peripheral milling; very rigid tool setup possible; can achieve tight tolerances
End mills	Incorporate cutting edges on both the face and the periphery; can be used for face cuts and periphery cuts	Allow multiple operations without changing cutters; cutters can have difficulty in maintaining dimensional accuracy due to long unsupported length
Special mills	Can be almost any design	Optimized for a particular task

**FIGURE 13.2.7** Three typical milling cutters. (From *ASM Handbook, Machining*, Vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 311. With permission.)

For highest efficiency in removing metal while minimizing chatter conditions, the feed per tooth should be as high as possible. The optimum feed rate is influenced by a number of factors (ASM, 1989b): type of cutter, number of teeth on the cutter, cutter material, workpiece machinability, depth of cut, width of cut, speed, rigidity of the setup, and machine power. The surface finish obtainable by milling can be quite good. A finish of 125  $\mu\text{in.}$  (3.2  $\mu\text{m}$ ) can be readily achieved under normal circumstances with HSS mills, and finishes of 63  $\mu\text{in.}$  (1.6  $\mu\text{m}$ ) are common if carbide tools are used. With careful selection of cutters and stringent control of process conditions, a finish of 10  $\mu\text{in.}$  (0.25  $\mu\text{m}$ ) can be produced.

**Process Limitations.** The initial cost of a milling machine is considerably greater than that of a planar or a shaper that can machine workpieces of similar size to similar finishes. Milling tools usually cost up to 50 times as much as tools for planers and shapers, and the setup time is usually longer. However, milling is far more efficient in removing material, and milling machines are commonly highly automated. Therefore, milling is preferred for production operations.

Grinding is often preferred to milling when the amount of metal to be removed is small and the dimensional accuracy and surface finish are critical. Milling and grinding are frequently used in combination.

## Broaching

**Description and Applications.** Broaching is a precision machining process. It is very efficient since both roughing cuts and finishing cuts are made during a single pass of the broach tool to produce a smooth surface, and further finishing is usually not necessary. Consequently, close tolerances can be readily achieved at a reasonable cost for high rates of production.

Broaches are expensive multitoothed cutting tools. Thus, the process is usually employed for low or high production when broaching is the only practical method to produce the required dimensional tolerance and surface quality. An example of the latter case is the dovetail slots in jet engine turbine disks.

*Principle of Operation.* Broaching is a machining process similar to planing. A broach is essentially a tapered bar into which teeth are cut, with the finishing teeth engaging last on the end with the larger diameter. A single broach has teeth for rough cutting, semifinishing, and finishing. Broaching involves pushing or pulling a broach in a single pass through a hole or across a surface. As the broach moves along the workpiece, cutting is gradual as each successive tooth engages the workpiece, removing a small amount of material. Overall machining forces are much greater than that of other machining methods, and consequently broaching is considered to be the most severe of all machining operations.

*Key System Components.* Broaching machines are categorized as horizontal or vertical, depending on the direction of broach travel. Industry usage is almost evenly divided between these two categories. The selection of machine type depends heavily on the configuration of the workpiece and available space in the factory, considering both floor space and vertical clearance requirements.

Broaches can be categorized by the method through which they are actuated (push or pull), by type of cut (internal or external), and by the construction of the broach body. Figure 13.2.8 depicts typical internal and external broaching operations. Table 13.2.11 describes broaches according to their construction.

**FIGURE 13.2.8** Internal (a) and external (b) broaching. (From *ASM Handbook, Machining*, vol. 16, 9th ed., ASM International, Metals Park, OH, 1989, 195. With permission.)

**TABLE 13.2.11** Types of Broaches

Broaches	Description	Application
Solid	One-piece broach produced from tapered bar stock; repair of broken teeth is difficult	Parts which require high dimensional accuracy and concentricity
Shell	Multipiece broach consisting of a main body, an arbor section over which a removable shell fits, and a removable shell containing the cutting edges; worn or damaged sections can be replaced	Internal and selected external broaching; sacrifices some accuracy and concentricity as the tool is not as stiff as a solid broach
Insert-type	Effectively a tool holder with inserts to perform the actual cutting; inserts are typically made from HSS or carbides; worn or damaged inserts can be readily replaced	Broaching large, flat surfaces

*Machine Tool and Machining Parameters.* Length and depth of cut have the most influence on determining the required broaching tool length. For internal cutting operations, as the cut length increases, more chip storage capacity must be provided between the cutting edges for the same amount of tooth advance. Cutting fluids are useful in preventing the work metal from adhering to the broach, and thus result in higher-quality surface finishes and increased broach life.

The primary consideration in the selection of optimum broaching speed is the trade-off between speed and wear rate. In general, steels are broached at 10 to 30 sfm (3 to 9 m/min); the harder the steel, the slower the broach speed (ASM, 1989b).

*Capabilities and Process Limitations.* Broaching can maintain tight tolerances during long production runs since metal-cutting operations are distributed among the different roughing and finishing teeth. Also, broach teeth can be repeatedly sharpened, allowing cutting efficiency and accuracy to be maintained.

Broaching is an extremely fast, precise machining operation. It is applicable to many workpiece materials over a wide range of machinability, can be accomplished in seconds, is readily automated, and can easily be done manually. For example, for low-carbon steels, tolerances of 0.002 in. (0.05 mm) can be readily attained with a surface finish of 60  $\mu\text{in.}$  (1.55  $\mu\text{m}$ ); if desired, tighter tolerances and surface finishes of 30  $\mu\text{in.}$  (0.8  $\mu\text{m}$ ) are possible without much additional effort. For difficult-to-machine superalloys, tolerances of 0.001 in. (0.025 mm) and surface finishes of 30  $\mu\text{in.}$  (0.8  $\mu\text{m}$ ) are commonly achieved in production (ASM, 1989b).

Broaching is rarely used for removing large amounts of material since the power required would be excessive. It is almost always more effective to use another machining method to remove the bulk of material and use broaching for finishing.

Since a broach moves forward in a straight line, all surface elements along the broach line must be parallel to the direction of travel. Consequently, the entire surface of a tapered hole cannot be broached. Also, cutting is done sequentially with the finishing teeth engaging last. Therefore, a blind hole can be broached only if a sufficiently long recess is provided to permit full travel of the broach.

The direction of travel of the broach cannot realistically be changed during a broaching stroke, except for rotating the tool. Thus, surfaces having compound curves cannot be broached in a single operation. On external surfaces, it is impossible to broach to a shoulder that is perpendicular to the direction of broach movement.

## Grinding

*Trevor D. Howes, John Webster, and Ioan Marinescu*

*Description and Applications.* Grinding, or abrasive machining, refers to processes for removing material in the form of small chips by the mechanical action of irregularly shaped abrasive grains that are held in place by a bonding material on a moving wheel or abrasive belt (Green, 1992). In surface-finishing operations (e.g., lapping and honing) these grains are suspended in a slurry and then are embedded in a roll-on or reference surface to form the cutting tool. Although the methods of abrasion may vary, grinding and surface-finishing processes are used in manufacturing when the accuracy of workpiece dimensions and surface requirements are stringent and the material is too hard for conventional machining.

Grinding is also used in cutoff work and cleaning of rough surfaces, and some methods offer high material-removal rates suitable for shaping, an area in which milling traditionally has been used.

Grinding is applied mainly in metalworking because abrasive grains are harder than any metal and can shape the toughest of alloys. In addition, grinding wheels are available for machining plastics, glass, ceramics, and stone. Conventional precision metal and ceramic components and ultraprecision electronic and optical components are produced using grinding.

*Mechanics of Grinding.* Three types of energy are involved in grinding (Andrew et al., 1985). *Rubbing energy* is expended when the grains (cutting edges) of the grinding wheel wear down. As they wear,

they cut less and produce increasing friction, which consumes power but removes less material. *Plowing energy* is used when the abrasive does not remove all of the material but rather plows some of it aside plastically, leaving a groove behind. *Chip-formation energy* is consumed in removing material from the workpiece as the sharp abrasive grain cuts away the material (or chip) and pushes it ahead until the chip leaves the wheel.

The grinding wheel experiences *attritious wear* as the abrasive grains develop wear flats from rubbing on the workpiece, or when grains break free from the bond material. Attritious wear gives rise to rubbing energy resulting from friction, and thus can lead to thermal damage as power consumption increases without an increase in material removal rate. The wheel can wear through *fracture*, predominating at relatively high in-feed rates. In this case, pieces of the abrasive grain break free and expose a new, sharp surface.

Materials can be classified as either easy to grind or difficult to grind. For *easy-to-grind materials*, most of the power consumption becomes invested in chip formation; thus, rubbing and plowing energy are minimal. *Difficult-to-grind materials* involve considerable rubbing and plowing energy since the force required to remove chips is comparatively high.

*Types of Grinding.* In *surface grinding*, the grinding wheel traverses back and forth across the workpiece. Grinding can take place by using either the periphery or side face of the wheel. The table holding the part may also reciprocate. Surface grinding is done most commonly on flat surfaces and surfaces with shapes formed of parallel lines, e.g., slots.

*Creep-feed grinding* is a form of surface grinding in which the wheel feeds into the workpiece at a low rate (0.4 to 40 in./min, 10 to 1000 mm/min) while grinding at a large depth of cut (0.04 to 0.4 in., 1 to 10 mm, or deeper). A large amount of material can be removed with one pass of the wheel, compared with conventional surface grinding in which the wheel makes many quick passes over the workpiece at slight depths of cut. This process is limited by the large amount of heat generated at the grinding arc which can result in thermal damage (grinding “burn”). Application of coolant is critical in creep-feed operations. CBN wheels, with their good heat transfer property, can also reduce the severity of burn (King and Hahn, 1986).

*Cylindrical grinding* produces round workpieces, such as bearing rings, although some machines can also grind tapered parts. The workpiece is mounted to a spindle and rotates as the wheel grinds it. The workpiece spindle has its own drive motor so that the speed of rotation can be selected. Both inner surfaces (internal cylindrical grinding) and outer (external cylindrical grinding) can be worked, although usually the same machine cannot do both.

There are three variants for *external grinding*:

- *Plain grinding* — the wheel carriage is brought to the workpiece on its spindle and in-feeds until the desired dimensions are reached
- *Traverse grinding* — the rotating workpiece is mounted on a table that reciprocates under the wheel; the grinding wheel is stationary except for its downward feed into the workpiece
- *Plunge grinding* — the table with the rotating workpiece is locked while the wheel moves into the workpiece until the desired dimensions are attained

*Centerless grinding* is a form of cylindrical grinding. In this method workpieces are not held in a centering chuck but instead rotate freely between a support, regulating wheel, and the grinding wheel. The force of the rotating grinding wheel holds the workpiece against the support. The supports are usually stationary and so a flow of lubricant is required to reduce friction between workpiece and support. An example of centerless grinding is shown in [Figure 13.2.9](#).

*Abrasive belt machines* use a flexible fabric coated with an abrasive stretched between two rollers, one of which is driven by a motor. Usually, the abrasive coating is aluminum oxide for steels and bronzes and silicon carbide for hard or brittle materials. In the metal industries, common use of such machines is for dry grinding of metal burrs and flash and polishing of surfaces. However, some fabrics permit use

**FIGURE 13.2.9** Through-feed and plunge centerless grinding. (Courtesy of T. D. Howes, John Webster, and I. Marinescu.)

of grinding fluids to enhance chip removal and provide cooling and lubrication, which results in better cutting action and longer belt life.

Honing, lapping, and polishing use abrasives to improve the accuracy of the form of a workpiece or the surface finish beyond the capabilities of grinding.

- *Honing* is a low-surface-speed operation, usually performed on an internal, cylindrical surface but possible also on external ones. Stock is removed by the shearing action of abrasive grains: a simultaneous rotary and reciprocating motion of fixed abrasive in the form of a stone or stick. Finishes range from under 1 to 50  $\mu\text{in.}$  (0.025 to 1.3  $\mu\text{m}$ ). The development of CBN has revolutionized the honing process because this material easily outperforms conventional abrasives such as aluminum oxide, lasting up to 100 times longer.
- *Superfinishing*, like honing, uses fixed abrasives in the form of a stone. Unlike honing, which has a helical motion inside a bore, superfinishing uses high-speed, axial reciprocation combined with slow rotation of the outside diameter of the cylindrical component being processed. The geometry produced by a previous operation generally is not improved.
- *Lapping* is a fine-finishing, abrasive machining process used to obtain superior finish and dimensional accuracy. Lapping is unlike other finishing processes because some of the abrasive is loose rather than bonded. In general, lapping occurs when abrasive grains in a liquid vehicle (called a slurry) are guided across a workpiece by means of a rotating plate.
- *Polishing* uses free abrasive, as in lapping, but requires a soft support unlike the relatively hard support used in lapping. The total depth of cut during polishing can be as little as nanometers where chemical interactions will play a stronger role than mechanical or physical interactions. When the depth of cut is greater than 1  $\mu\text{in.}$  (0.025  $\mu\text{m}$ ), the interactions are usually of a mechanical nature. Many industrial components, especially electronic and optical, required highly polished surfaces.

**Key System Components.** A *grinding wheel* consists of thousands of small, hard grains of abrasive material held on the surface in a matrix of bond material (Table 13.2.12). The bond material is matched to the characteristics of the grain to retain the grain sufficiently to maximize its use before shedding it.

**TABLE 13.2.12 Common Grinding Wheel Abrasives**

Abrasive	Characteristic	Grinding Application
Aluminum oxide	Friable	Steel: soft or hardened, plain or alloyed
Seeded gel aluminum oxide	More friable and expensive than aluminum oxide	Steel: soft or hardened, plain or alloyed; use at higher stock removal rates
CBN	Tough; increased life at higher speeds; high accuracy and finish	Hardened steels; tough superalloys
Synthetic diamond	Hardest of all abrasives; can be friable; seldom need dressing/truing	Grinding hardened tool steels, cemented carbides, ceramics, and glass; cutting and slicing of silicon and germanium wafers
Silicon carbide	Friable	Cast iron; nonferrous metals; nonmetallics

The structure of the wheel formed by specific types of grains and bonds determines its characteristics. The grains are spaced apart depending on the cutting required. Widely spaced grains (open structure) cut aggressively, which is useful for hard materials or high rates of material removal, but which tends to produce coarse finishes. Closely packed grains (dense structure) make fine and precise cuts for finish grinding.

Grain spacing is also important for temporary storage of chips of material removed from the workpiece. An open structure is best for storing chips between the grains, which are then released after wheel rotation moves the grains away from the workpiece. An open structure also permits more coolant to enter the spaces to dissipate heat.

The bonding material is important to grinding performance. This material is weaker than the cutting grains so that ideally, during grinding, the grain is shed from the wheel surface when it becomes dull, exposing new sharp grains. For instance, wheels with friable abrasives that fracture to expose new, sharp grains must retain the grains longer to maximize the use of the abrasive; these wheels use stronger bonding materials. The four types of bond material are vitrified, resinoid, rubber, and metal. [Table 13.2.13](#) shows their properties and uses.

**TABLE 13.2.13 Characteristics of Grinding Wheel Bonds**

Bond Type	Characteristic	Application
Rubber	Relatively flexible	Wet cut-off wheels; high-finish work; regulating wheels for centerless grinding
Resinoid (thermoplastic)	Relatively flexible	Rough grinding; portable grinders
Vitrified (glasslike)	Endure high temperatures; resist chemical effects of coolants; sensitive to impacts	Most widely used of all bonding materials
Metal	Electrodeposited nickel or sintered metal powder often used to bond CBN and diamond abrasives; has long wheel life; electrically conductive	Aggressive cutting operations such as creep-feed and deep grinding; electrically conductive grinding (e.g., electrochemical methods)

Grinding wheels must be resharpened on occasion. *Dressing*, not always required, sharpens the grains before grinding. *Truing* operations ensure the wheel conforms to the required cutting shape and will rotate concentrically to its spindle.

Because grinding wheels have relatively high mass and high operating speed, they must be *precisely balanced*. Imbalance causes vibrations that reduce the quality of the workpiece, hasten the wear of the spindle and bearings of the machine, affect other devices mounted on the grinder, and possibly transmit vibration from the grinder through the shop floor to other machines. Mounting of the wheel on the spindle and subsequent wheel wear can degrade the balance of the rotating system. Wheels are balanced by moving counterweights on balancing flanges. Some machines have an automatic balancer that shifts internal counterbalance masses.

*Coolants* are usually sprayed on the grinding zone to cool the wheel and workpiece, lubricate the surface to reduce grinding power, and flush away the chips. Excessive heat can damage both the wheel and workpiece by inducing undesirable physical changes in materials, such as metallurgical phase changes or residual stresses, or softening of the bond material in the grinding wheel. Coolant application is especially important in creep-feed grinding where the wheel-to-workpiece contact arc is long, heat generation is high, and the chips produced and abrasive lost from the wheel must be flushed away.

Selecting the type of *coolant system* depends on many factors, including the grinding wheel speed, material removal rate, depth of cut, and wheel/workpiece materials. The type of fluids used in this system requires consideration of both physical and environmental issues. Use of oil fluids can favor the formation of preferred residual stress patterns and better surface finish, and these oils can be recycled for long periods. However, oils present health risks, potential for groundwater contamination, and fire risks (especially with high-sparking superalloys). Water-based fluids offer far fewer environmental problems. Disadvantages of water-based fluids lie in their limited life expectancy of 3 to 12 months. Also, the relatively low viscosity of a water-based fluid at high velocity promotes a dispersed jet which reduces cooling capacity.

*Capabilities and Process Limitations.* Surface grinding can be a cheaper, faster, and more precise method than milling and planing operations. For profiled shapes, the grinding wheel can be dressed with less cost and inconvenience than changing milling setups for different parts. Grinding can be used as a high-stock-removal process; for example, creep-feed grinding has a depth of cut more typical of milling operations (0.1 in., 2.54 mm, and deeper). Creep-feed grinding is used for machining materials that are too difficult to work by other machining methods.

High-speed grinding can be extremely efficient. CBN abrasive allows high rates of material removal because CBN transfers heat away from the grinding zone due to its relatively high thermal conductivity, and CBN does not react with steel.

Considerable effort has been expended on modeling and testing the thermal limitations of grinding (Malkin, 1989). Nearly all models depend on a fundamental model which depends on sliding contact theory. All models confirm the following guidelines for grinding with conventional abrasives when burn is a limitation: decrease wheel speed, increase workpiece speed, use softer-grade wheels.

Grinding operations can be limited by two types of vibration:

- *Forced vibration.* Typical causes are out-of-balance wheels, nonuniform wheels, couplings, belts, noise from hydraulic systems, bearing noise, and forces transmitted from the floor to the grinding machine.
- *Self-excited vibration.* Typical causes are wheel wear, workpiece surface error regeneration, wheel loading, and wear flats. Typical solutions include softer grinding wheels, flexible (for dampening) wheel structures, and stiffer machine structures.

### *Nontraditional Machining*

#### *K. P. Rajurkar and W. M. Wang*

The processes described below are representative of the types most likely to be encountered. The references listed at the end of the section contain detailed information on these processes, plus those that are not described here.

#### **Electrical Discharge Machining (EDM)**

*Description and Applications.* The EDM process machines hard materials into complicated shapes with accurate dimensions. EDM requires an electrically conductive workpiece. Process performance is unaffected by the hardness, toughness, and strength of the material. However, process performance is a function of the melting temperature and thermal conductivity. EDM is currently widely used in aerospace, machinery, and die and mold industries.

There are two types of EDM processes:

- Die-sinking EDM uses a preshaped tool electrode to generate an inverted image of the tool on the workpiece; commonly used to generate complex-shaped cavities and to drill holes in different geometric shapes and sizes on hard and high-strength materials.
- Wire EDM (WEDM) uses a metal wire as the tool electrode; it can generate two- or three-dimensional shapes on the workpiece for making punch dies and other mechanical parts.

*Principle of Operation.* EDM removes workpiece materials by harnessing thermal energy produced by pulsed spark discharges across a gap between tool and workpiece. A spark discharge generates a very small plasma channel having a high energy density and a very high temperature (up to 10,000°C) that melts and evaporates a small amount of workpiece material. The spark discharges always occur at the highest electrical potential point that moves randomly over the machining gap during machining. With continuous discrete spark discharges, the workpiece material is uniformly removed around the tool electrode. The gap size in EDM is in the range of 400  $\mu\text{in.}$  to 0.02 in. (0.01 to 0.5 mm), and is determined by the pulse peak voltage, the peak discharge current, and the type of dielectric fluid.

*EDM Power System.* The discharge energy during EDM is provided by a direct current pulse power generator. The EDM power system can be classified into RC, LC, RLC, and transistorized types. The transistorized EDM power systems provide square waveform pulses with the pulse on-time usually ranging from 1 to 2000 msec, peak voltage ranging from 40 to 400V, and peak discharge current ranging from 0.5 to 500 A. With the RC, LC, or RLC type power system, the discharge energy comes from a capacitor that is connected in parallel with the machining gap. As a result of the low impedance of plasma channel, the discharge duration is very short (less than 5 msec), and the discharge current is very high, up to 1000 A. The peak voltage is in the same range of transistorized power systems.

The transistorized power systems are usually used in die-sinking EDM operations because of their lower tool wear. Capacitive power systems are used for small hole drilling, machining of advanced materials, and micro-EDM because of higher material removal rate and better process stability. WEDM

power generator usually is a transistor-controlled capacitive power system that reduces the wire rupture risk. In this power system, the discharge frequency can be controlled by adjusting the on-time and off-time of the transistors that control the charging pulse for the capacitor connected in parallel with the machining gap.

*Key System Components.* The machining gap between tool and workpiece during EDM must be submerged in an electrically nonconductive *dielectric fluid*. In die-sinking EDM, kerosene is often used as a dielectric fluid because it provides lower tool wear, higher accuracy, and better surface quality. Deionized water is always used as a dielectric fluid in WEDM to provide a larger gap size and lower wire temperature in order to reduce the wire rupture risk. This fluid also serves to flush debris from the gap and thus helps maintain surface quality.

Copper and graphite are commonly used as die-sinking *EDM tool materials* because of the high electrical conductivity and high melting temperature and the ease of being fabricated into complicated shapes. The wire electrode for WEDM is usually made of copper, brass, or molybdenum in a diameter ranging from 0.01 to 0.5 mm. Stratified copper wire coated with zinc brass with diameter of 0.25 mm is often used.

In the traditional *die-sinking EDM process*, the tool is fabricated into a required shape and mounted on a ram that moves vertically. The spark discharges can only occur under a particular gap size that determines the strength of electric field to break down the dielectric. A servo control mechanism is equipped to monitor the gap voltage and to drive the machine ram moving up or down to obtain a dischargeable gap size and maintain continuous sparking. Because the average gap voltage is approximately proportional to the gap size, the servo system controls the ram position to keep the average gap voltage as close as possible to a preset voltage, known as the servo reference voltage.

In a WED machine, the wire electrode is held vertically by two wire guides located separately above and beneath the workpiece, with the wire traveling longitudinally during machining. The workpiece is usually mounted on an *x-y* table. The trajectory of the relative movement between wire and workpiece in the *x-y* coordinate space is controlled by a CNC servo system according to a preprogrammed cutting passage. The CNC servo system also adjusts the machining gap size in real time, similar to the die-sinking EDM operation. The dielectric fluid is sprayed from above and beneath the workpiece into the machining gap with two nozzles.

The power generators in WED machines usually are transistor-controlled RC or RLC systems that provide higher machining rate and larger gap size to reduce wire rupture risks. In some WED machines, the machining gap is submerged into the dielectric fluid to avoid wire vibration to obtain a better accuracy. The upper wire guide is also controlled by the CNC system in many WED machines. During machining, the upper wire guide and the *x-y* table simultaneously move along their own preprogrammed trajectories to produce a taper and/or twist surface on the workpiece.

*Machining Parameters.* The polarity of tool and workpiece in EDM is determined in accordance with the machining parameters. When the discharge duration is less than 20  $\mu\text{sec}$ , more material is removed on the anode than that on the cathode. However, if the discharge duration is longer than 30  $\mu\text{sec}$ , the material-removal rate on the cathode is higher than that on the anode. Therefore, with a transistorized power system, if the pulse on-time is longer than 30  $\mu\text{sec}$ , the tool is connected as anode and the workpiece is connected as cathode. When the on-time is less than about 20  $\mu\text{sec}$ , the polarity must be reversed. With an RC, LC, or RLC power system, since the discharge duration is always shorter than 20  $\mu\text{sec}$ , the reversed polarity is used.

With transistorized EDM power systems, the machining rate and surface finish are primarily influenced by the peak current. The machining rate increases with the peak current. The relationship between the machining rate and pulse on-time is nonlinear, and an optimal pulse on-time exists. Reducing peak current improves the surface finish, but decreases the machining rate.

*Capabilities and Process Limitations.* Die-sinking ED machines with transistorized power systems under good gap-flushing conditions can attain a material-removal rate as high as 12  $\text{mm}^3/\text{min}/\text{amp}$  (for

a steel workpiece). The wire cut EDM process can cut ferrous materials at a rate over 100 mm<sup>2</sup>/min. A surface roughness value of 0.01 in. (0.2 mm) can be obtained with a very low discharge current. The tool wear ratio can be controlled within 1% during rough machining and semifinishing with the transistorized power generator. Dimensional tolerance of  $\pm 118 \mu\text{in.}$  (3  $\mu\text{m}$ ) and taper accuracy of 20 to 40  $\mu\text{in.}$  (0.5 to 1  $\mu\text{m/mm}$ ) with both die-sinking and WEDM can be obtained.

EDM can machine materials having electrical conductivity of  $10^{-2} \text{ W}^{-1} \text{ cm}^{-1}$  or higher. An average current density more than 4 A/cm<sup>2</sup> tends to cause substantial tool wear and unstable machining, and may lead to dielectric fire. This factor largely limits the productivity of EDM. During machining a deep cavity using die-sinking EDM under difficult flush condition, arc discharges occur, and the resultant thermal damage on workpiece substantially limits the productivity and the machined surface quality. Dielectric properties also impose additional constraints.

### Electrical Chemical Machining (ECM)

*Description and Applications.* The ECM process uses the electrochemical anodic dissolution effect to remove workpiece material. Like die-sinking EDM, the tool electrode of ECM is preshaped according to the requirements of the workpiece. During machining, the inverted shape of the tool is gradually generated on the workpiece. ECM machines complex contours, irregular shapes, slots, and small, deep, and/or noncircular holes. Typical applications of ECM include machining nickel-based superalloy turbine blade dovetails, slots in superalloy turbine disks, engine castings, gun barrel rifles, and forging dies. ECM is also used for deburring, surface etching, and marking.

*Principle of Operation.* Electrolyte fluid is forced through the gap between tool and workpiece during ECM. A low-voltage and high-current DC power system supplies the machining energy to the gap. The tool electrode of ECM must be connected as cathode and the workpiece must be connected as anode. The electrochemical anodic dissolution phenomenon dissolves workpiece surface material into metal ions. The electrolyte fluid flushes the metal ions and removes heat energy generated by the deplating actions. The gap size in ECM is in the range of 0.004 to 0.04 in. (0.1 to 1 mm). ECM process performance is independent of the strength, hardness, and thermal behavior of workpiece and tool materials.

*Key System Components.* Copper, brass, stainless steel, and titanium are commonly used as *ECM tool electrode materials* due to their good electrical conductivity, resistance to chemical erosion, and ease of being machined into desired shapes. The geometric dimensions of the machined surface generated by ECM depend on the shape of tool and the gap size distribution.

The structure of an EC machine varies with the specific applications. An ECM must have a tool feed system to maintain the machining gap, a power system to supply the power energy, and a fluid-circulating system to supply the electrolyte and to flush the machining gap. The power system used in ECM is a DC power source with the voltage ranging from 8 to 30 V and a high current in the range of 50 to 50,000 A, depending on the specific design of the power system.

The *electrolyte* is the medium enabling the reaction of electrochemical dissolution occurring on the anode. The electrolyte can be classified into categories of aqueous and nonaqueous, organic and nonorganic, alkaline and neutral, mixed and nonmixed, and passivating and nonpassivating, and acidic. The electrolyte is selected according to the type of workpiece material, the desired accuracy, surface finish requirements, and the machining rate. Neutral salts are used in most cases. Acid electrolytes are used only for small hole drilling when the reaction products must be dissolved in the electrolyte.

*Machining Parameters.* ECM performance is mainly influenced by electrical parameters, electrolyte, and geometry of tool and workpiece. The electrical parameters include machining current, current density, and voltage. ECM systems with 50 to 50,000 A and 5 to 30 V DC are available, and the current density can be in the range of 10 to 500 A/cm<sup>2</sup>. Key electrolyte parameters consist of flow rate, pressure, temperature, and concentration. Important parameters of tool and workpiece geometry are contour gradient, radii, flow path, and flow cross section. When the tool feed rate equals the machining rate, an equilibrium gap size is obtained; this is critical to maintaining shaping accuracy.

The electrolyte selection also plays an important role in ECM dimension control. In this regard, the sodium nitrate solution is preferable because the metal-removal rate at smaller gap size locations is higher than at other places. Therefore, the characteristics of current efficiency in ECM influence the uniformity of the gap size distribution. ECM accuracy has recently been shown to improve with pulsed voltage (instead of continuous voltage) and an appropriate set of pulse parameters (on-time, off-time, etc.).

*Capabilities and Process Limitations.* ECM is capable of machining any electrically conductive metallic material, and the process is generally unaffected by the hardness, strength, and thermal behaviors of materials. This process can be used to machine parts with low rigidity such as parts with thin walls. Machining rates of 2 to 2.5 cm<sup>3</sup>/min/1000 A current, surface roughness of 4 to 50 μin. (0.1 to 1.2 μm), and accuracy of 400 μin. to 0.01 in. (10 to 300 μm) can be achieved with ECM. The available ECM equipment can machine a 0.04 to 80 in. (1 to 2000 mm) long workpiece. The typical energy consumption is 300 to 600 J/mm<sup>3</sup>.

The machining rate and surface finish with ECM are much higher than that with EDM due to higher allowable current density and the molecular level of material removal. The machining accuracy, however, is substantially lower than EDM and is much more difficult to control.

The gap size distribution is influenced by many factors including the type of electrolyte, electrolyte flow rate and flow pattern, electrolyte temperature, current density of machining, etc. Therefore, the gap size distribution is not uniform in most cases and is difficult to determine analytically. The shape of machined surface by ECM will not be a perfect mirror image of the tool electrode. In order to achieve an acceptable accuracy, the tool shape must be modified by using trial-and-error method in test machining before machining of actual workpieces.

ECM cannot machine materials with electrical conductivity less than 10<sup>3</sup> W<sup>-1</sup> cm<sup>-1</sup>. ECM cannot produce very sharp corners (less than 800 μin., 0.02 mm, radius). The machining rate is limited by the electrolytic pressure (less than 5 MPa) and boiling point as well as the applied current (less than 50,000 A). The gap size which determines the final shape and accuracy is limited to 800 μin. to 0.004 in. (0.02 to 0.1 mm).

ECM generates a large amount of sludge and spent electrolyte. This waste requires significant processing before it can be safely disposed of.

## **Water and Abrasive Jet Machining**

*Description and Application.* *Water jet machining (WJM)* and *abrasive water jet machining (AWJM)* are used in many applications. In the WJM process, relatively soft workpiece materials are cut by a high-velocity water jet; e.g., food, wood, paper, plastic, cloth, rubber, etc. The AWJM process uses the fine abrasive particles mixed in the water jet to machine harder workpiece materials. The AWJM is used for drilling, contour cutting, milling, and deburring operations on metal workpieces, as well as for producing cavities with controlled depths using multipass and non-through-cutting methods. The cutting path of the WJM and AWJM can be controlled by a CNC system according to a preprogrammed program.

*Principle of Operation and Machine Structures.* During WJM, the workpiece material is removed by the mechanical energy generated by the impact of a high-velocity water jet. In a water jet machine, a high-pressure pumping system increases the pressure of water in the pipe system, and the pressurized water is sprayed from a nozzle with a small diameter to generate a high-velocity water jet.

In the AWJM process, pressurized water is sprayed from an orifice in the nozzle body into a mixing chamber to generate a negative pressure that absorbs the abrasive particles (supplied by an abrasive feed hose) into the water jet. The water jet/abrasive grain mixture is then sprayed through a tungsten carbide nozzle. The abrasive grains in the high-velocity water jet provide small cutting edges that remove material. The relative distance between water jet nozzle and workpiece is controlled by a two- or three-dimensional CNC system. This process can be used to generate a complicated shape.

*Process Parameters and Limitations.* The key parameters are the water and/or abrasive flow velocity, abrasive grain size, and mixing tube (nozzle) length and diameter. The typical water flow velocity is in the range of 2000 to 3000 ft/sec (600 to 900 m/sec) as determined by the water pressure. The water pressure in WJM and AWJM is very high, up to  $2.7 \times 10^6$  psi (400 MPa), and the nozzle diameter is in the range of 0.003 to 0.08 in. (0.8 to 2 mm). The abrasive flow rate is governed by the water flow rate and the mixing density, and can be controlled up to 10 g/sec. Abrasive particles are usually in the range of 60 to 150 mesh size. Increasing water jet flow velocity increases cutting depth. The taper error of cutting is determined by the traverse rate that describes the ratio between the material removal and the cutting depth and width. This parameter is influenced by the water and abrasive velocity and cutting speed. Proper selection of AWJ parameters is essential for the elimination of burrs, delaminations, and cracks.

Limitations of the process include stray cutting and surface waviness, high equipment costs, hazard from the rebounding abrasive, high noise levels, and short nozzle lifetimes due to wear and abrasion.

### Ultrasonic Machining

*Description and Applications.* *Ultrasonic machining* (USM) is a process that uses the high velocity and alternating impact of abrasive particles on the workpiece to remove material. The abrasive particles are mixed in a slurry that fills the machining gap between the tool and workpiece. The alternating movement of abrasive particles is driven by the vibration of the frontal surface of tool at an ultrasonic frequency. The ultrasonic machining process can machine hard and brittle materials.

USM is often used for machining of cavities and drilling of holes on hard and brittle materials including hardened steels, glasses, ceramics, etc. Rotary ultrasonic machining (RUM) is a new application that uses a diamond grinding wheel as the tool for drilling, milling, and threading operations. During RUM, the tool is rotating at a high speed up to 5000 rpm and vibrating axially at ultrasonic frequency. This process is able to drill holes with diameter from 0.02 to 1.6 in. (0.5 to 40 mm) at depths up to 12 in. (300 mm). The material removal rate of  $6 \text{ mm}^3/\text{sec}$  can be obtained with the RUM process. The tolerance of  $\pm 300 \text{ }\mu\text{in.}$  ( $\pm 0.007 \text{ mm}$ ) can be easily achieved with both conventional and rotary ultrasonic processes.

*Principle of Operation.* In the USM process, the machining gap between tool and workpiece is filled with an abrasive slurry composed of an oil mixed with abrasive particles, with the frontal surface of the tool vibrating at ultrasonic frequency to provide the machining energy. The inverted shape of the tool is gradually generated on the workpiece. Material removal by the USM process is very complex. When the machining gap is small, the material may be removed as the frontal surface of the tool moves toward the workpiece, hitting an abrasive particle that impacts the workpiece surface. Material can also be removed by the impact of the abrasive particles when the machining gap is relatively large. In this case, the abrasive particles are accelerated by the pressure of slurry due to the ultrasonic vibration of the frontal surface of the tool. Also, ultrasonic-induced alternating pressure and cavitation in the slurry assist material removal.

*Key System Components.* The ultrasonic vibration in USM is generated by an *ultrasonic generator*. The ultrasonic generator consists of a signal generator, a transducer, and a concentrator. The signal generator produces an electrical signal whose voltage and/or current is changing at an ultrasonic frequency to drive the transducer. The frequency of the electrical signal can be adjusted in the range of 10 to 40 kHz.

The transducer converts the electrical voltage or current into the mechanical vibration. Two types of transducers are commonly used in USM: magnetostrictive and piezoelectric.

- The *magnetostrictive transducer* was extensively used prior to 1970. This transducer is constructed by surrounding a number of sheets of magnetostrictive material with a coil. When the strength of the electric current in the coil changes at an ultrasonic frequency, a mechanical ultrasonic vibration is generated in the magnetostrictive material. This transducer has a low energy conversion efficiency, usually less than 30%.

- The *piezoelectric ultrasonic transducer* is commonly used today. The geometrical dimensions of this transducer vary with the change in the applied electric field. A mechanical ultrasonic vibration is generated when the strength of the electric voltage applied across the transducer material changes at an ultrasonic frequency. This transducer has an extremely high energy conversion efficiency, up to 95%. The amplitude of the ultrasonic vibration generated directly by the transducer is very small, about 400  $\mu\text{in.}$  (0.01 mm). A concentrator is used for amplifying the amplitude into a level that is acceptable for USM. The transducer is mounted on the larger end of the concentrator; the tool is mounted on the smaller end.

In the ultrasonic machine, the ultrasonic generator is held vertically on the ram that moves vertically, and the workpiece is mounted on an  $x$ - $y$  table that determines the relative position between tool and workpiece. During machining, a force providing pressure between the tool and workpiece is added through the ram mechanism.

*Process Parameters and Limitations.* The material-removal rate during USM increases with an increase in the amplitude of ultrasonic vibration, grain size of the abrasive particles, and pressure between the tool and workpiece. The surface finish is essentially determined by the grain size for a given workpiece material; i.e., the smaller the grain size, the better surface finish. The abrasive grains used in USM are usually in the range of 100 to 900 mesh number.

The USM process is limited by the softness of the material. Workpiece materials softer than Rockwell C40 result in prohibitively long cycles. The best machining rate can be obtained on materials harder than Rockwell C60.

## Phase-Change Processes

Phase-change processes produce parts from materials originally in the liquid or vapor phase. These include processes such as metal casting and injection molding of polymers. The two most commonly used metal-casting processes are described below. The references listed at the end of the section contain detailed information on all phase-change unit processes.

### Advantages and Applications of Metal Casting

Metal casting is one of the primary methods of producing bulk shapes. Very complex shapes can be cast from nearly every metal, making casting an extremely versatile process. Castings are made in sizes that range from fractions of an ounce to hundreds of tons.

The selection of the best molding and casting process for an application can be complex, and is governed by many factors which include casting size, variation in thickness of the casting sections, required mold strength, required surface finish and dimensional accuracy, production rates, environmental factors (e.g., reclamation of the sand and type of sand binder), and cost. Casting processes can be considered to fall into five categories (Kanicki, 1988):

- Conventional molding processes — green sand, shell, flaskless
- Precision molding and casting processes — investment, permanent mold, die casting
- Special molding and casting processes — vacuum molding, evaporative pattern casting, centrifugal casting

- Chemically bonded self-setting sand molding — no-bake, sodium silicate
- Innovative molding and casting processes — unbonded sand molding (Patz and Piwonka, 1988), rheocasting, squeeze casting, electroslag casting

This section discusses the most widely used conventional molding process, green sand, and the most widely used precision molding and casting process, investment casting. The reference list at the end of the section should be consulted for detailed information on all casting processes.

### Casting Defects and Design Considerations

Properly designed and manufactured castings provide many advantages, and are competitive with other unit process methods. Success with casting processes, as with every process, requires design and process engineers knowledgeable regarding the advantages and limitations of casting processes so that appropriate design and process choices can be made that avoid or minimize the occurrence of defects.

Table 13.2.14 summarizes the most common defects that occur during casting and suggests design and process changes that can avoid or reduce the effect of the defects. However, the suggested mitigation strategies may introduce different casting defects or the evolution of other problems, so each change should be carefully evaluated with regard to the system as a whole.

### Green Sand Casting Processes

*Description and Applications.* Sand-mold casting is adaptable to a very wide range of alloys, shapes, sizes, and production quantities. Hollow shapes can be produced in these castings through the use of cores. Sand-mold casting is by far the most common casting process used in industry; some estimates are that as many as 90% of industrial castings use the sand-mold casting process (O’Meara et al., 1988). Green sand molding is currently the most widely used of all sand casting methods, although dry sand methods are preferred for very large castings. “Green” sand refers to the fact that water is added to activate the clay binder. In dry sand molding, the moisture is removed prior to casting.

Green sand-mold casting involves mixing sand with a suitable clay binder (usually a bentonite clay) and other additives, and packing the sand mixture tightly around a pattern that is constructed from the part design, but the pattern is not an exact replica of the part since various dimensional allowances must be made to accommodate certain physical effects. After extracting the pattern from the sand mold, a cavity is left behind that corresponds to the shape of the pattern. Next, molten metal is poured into this cavity and solidifies into a cast replica of the desired part. After the casting cools, the sand is readily removed from the casting and may be reclaimed for further use.

*Key System Components.* A *mold pattern* is constructed from the casting design with suitable modifications. Depending on the complexity of the part, CAD/CAM programs are able to design patterns that require very little adjustment to achieve desired solidification control and dimensional accuracy in the resulting casting (Berry and Pehlke, 1988). The computation is complex and cannot be easily done for complex shapes. The principal adjustments that must be made to translate a part design to a mold design result from many considerations (ASM, 1988). One needs to

- Compensate for shrinkage of the sand during the drying/curing operations
- Compensate for expansion of the sand caused by the rapid introduction of the molten metal into the mold
- Compensate for contraction of the liquid metal during freezing
- Allow easy extraction of the pattern from the packed sand through a taper on the vertical sides of the pattern
- Add a gating network to allow molten metal to smoothly flow into the cavity
- Add risers (including size), as required in key locations to continue feeding molten metal into the solidifying casting
- Add provisions for core prints, as required, to anchor cores that produce internal cavities which could not be directly molded from the pattern

**TABLE 13.2.14 Typical Casting Defects and Mitigation Strategy**

<b>Casting Defect</b>	<b>Description and Cause</b>	<b>Mitigation Strategy</b>
Cold shuts	Appear as folds in the metal — occurs when two streams of cold molten metal meet and do not completely weld Possible causes: • Interruption in the pouring operation • Too slow a pouring rate • Improperly design gating	Pour as quickly as possible Design gating system to fill entire mold quickly without an interruption Preheat the mold Modify part design Avoid excessively long thin sections
Hot tears and cracks	Hot tears are cracklike defects that occur during solidification due to overstressing of the solidifying metal as thermal gradients develop Cracks occur during the cooldown of the casting after solidification is complete due to uneven contraction	Fill mold as quickly as possible Change gating system; e.g., use several smaller gates in place of one large gate Apply thermal management techniques within the mold (e.g., chills or exothermic material) to control solidification direction and rate Insulate the mold to reduce its cooling rate Modify casting design: • Avoid sharp transitions between thin and thick sections • Taper thin sections to facilitate establishment of appropriate solidification gradients • Strengthen the weak section with additional material, ribs, etc.
Inclusions	Presence of foreign material in the microstructure of the casting Typical sources: • Furnace slag • Mold and core material	Modify gating system to include a strainer core to filter out slag Avoid metal flow turbulence in the gating system that could cause erosion of the mold Improve hardness of the mold and core
Misruns	Incomplete filling of the mold cavity Causes: • Too low a pouring temperature • Too slow a pouring rate • Too low a mold temperature • High backpressure from gases combined with low mold permeability • Inadequate gating	Control mold and metal temperature Increase the pouring rate Increase the pouring pressure Modify gating system to direct metal to thinner and difficult-to-feed sections quicker
Porosity	Holes in the cast material Causes: • Dissolved or entrained gases in the liquid metal • Gas generation resulting from a reaction between molten metal and the mold material	Pour metal at lowest possible temperature Design gating system for rapid but uniform filling of the mold, providing an escape path for any gas that is generated Select a mold material with higher gas permeability
Microshrinkage	Liquid metal does not fill all the dendritic interstices, causing the appearance of solidification micro-shrinkage	Control direction of solidification • Design gating system to fill mold cavity so that solidification begins at the extremities and progresses toward the feed gate • Lower the mold temperature and increase the pouring temperature • Add risers, use exothermic toppings to maintain temperature longer • Control cooling rate using chills, insulators, etc. in selected portions of the mold

There are basically three types of molding methods which are categorized by the resulting hardness or density of the sand mold (O'Meara et al., 1988; Brown, 1988):

### Low-density molding

- *Hand-ramming* is the oldest, slowest, and most variable method for packing sand around the pattern. It is rarely used for production, but can be employed for prototypes or very limited production runs.
- *Jolt* machines operate with the pattern mounted on a table which is attached to the top of an air piston. Typically, a flask is placed on the table with the pattern centered in the flask cavity. The flask is filled with sand. Compressed air lifts the piston, and then the air is released, allowing the entire assembly to fall with a sharp jolt. The sequence can be repeated. The sand is compacted by its own weight and is densest at the pattern plate.
- *Jolt-squeeze* molding machines employ the same pattern equipment as the jolt machines but after the jolting operation, the sand is squeezed by hydraulic pressure to improve the packing uniformity in the mold.

### Medium-density molding

- *Rap-jolt machines* are improved versions of the low-pressure machines, capable of exerting higher pressure to compact the sand.
- *Sand slingers* direct sand into a mold from a rotating impeller. Sand-packing density is a function of the centrifugal velocity of the impeller. This method is particularly useful for large molds.

### High-pressure molding

- *Pressure wave* methods allow the sand to gravity fill the mold. Then, the top of the mold is sealed and a high-pressure wave is created by a controlled explosion of a combustible gas or by the rapid release of air pressure.
- *Horizontal flaskless molding* utilizes a pattern carrier to support the top half (cope) and bottom half (drag) of the mold pattern. The cope and drag are spaced apart in the carrier, and the space is evacuated. The molding setup is depicted in [Figure 13.2.10](#). Vents in the pattern cause sand to be drawn into the mold. When the mold is filled, it is tightly squeezed.

**FIGURE 13.2.10** High-pressure vacuum-fill squeeze machine. (From *ASM Handbook, Machining*, Vol. 15, 9th ed., ASM International, Metals Park, OH, 1989, 343. With permission.)

The details of the *metal pouring* operation vary quite a bit depending on the metal, the material specification, the furnace type, and the foundry layout. A ladling method using gravity pressure is commonly used to transfer the molten metal, which may be alloyed, degassed, etc. immediately before it is discharged into the poring basin that feeds the gating system of the castings.

A *gating system* must allow complete fill of a mold cavity without causing flow turbulence that can entrap loose sand or slag and feed shrinkage as the liquid metal within the mold cools. The gating system should be designed to promote progressive solidification from the point most distant from the gate toward the gate.

A *riser* is a reservoir of molten metal that is attached to the casting. It feeds the voids that develop within the casting as the liquid metal cools and begins to solidify. A thin skin of frozen metal first forms in a shell around the outer part of the mold cavity immediately after the metal is poured. This rigid shell serves as a mold for the remainder of the casting. The volume lost by the shrinkage of the metal as it solidifies within this shell must be replaced from a liquid metal source, such as a riser or a feeding gate, to prevent internal porosity. Risers are subsequently removed from the casting.

Management of thermal gradients within the solidifying casting is essential to minimize shrinkage. The solidification of risers can be slowed by the use of an *exothermic material* placed on top of a riser. The heat generated by this material can allow the riser to continue to feed the casting until it is solidified. *Chills* can be used to reduce the local temperature at the mold-casting interface, and thus accelerate freezing in selected locations, thereby establishing the solidification direction. Chills are usually metal inserts strategically placed in the mold. The mold can also be *insulated* to reduce the overall cooling rate of the casting if necessary to reduce residual stresses, but the metallurgical effect must be carefully considered.

In most cases, *electric furnaces* are used for melting, and *pouring* is nonpressurized.

*Influence of Process on Part Design.* Properly designed gating systems and risers should produce completely solid castings. A number of design rules for the gating and risering system have been developed for casting various metals to achieve continuous feeding of the solidifying casting. These rules are embedded in computer programs that aid design of casting molds and layouts.

It may be less expensive and easier to change the design than to develop a complex thermal management system within the mold. Typical design changes to evaluate include

- Thickening thin sections that feed heavier, more remote sections
- Reducing the mass of the remote thick section
- Adding a riser to feed separately the remote thick section

*Process Limitations.* Each production step contributes to *dimensional variations* in a sand casting. For instance, dimensions are affected by the sand-packing density, by the process of withdrawing the pattern from the sand, by the moisture content of the sand, and by both the temperature of the molten metal and the speed with which it enters the mold cavity. The result is that sand casting is not inherently a precision process.

The surface finishes of sand castings are controllable only within rather wide limits (ASM, 1988). Normally, the maximum allowable surface roughness is specified, and any smoother surface is acceptable. For instance, casting steel in green sand can have a surface roughness varying from 500 to 2000  $\mu\text{in}$ . (12 to 50  $\mu\text{m}$ ), and aluminum from 125 to 750  $\mu\text{in}$ . (3 to 20  $\mu\text{m}$ ). These values can be improved in certain instances through the application of coatings on the sand mold.

Porosity cannot be prevented in all cases. Changes to the part design and postcasting processing, such as hot isostatic pressing (HIP), should be considered.

## Investment Casting

*Description and Applications.* Investment castings are noted for their ability to reproduce extremely fine details and conform to very tight tolerances. As a result, these castings are used in critical, demanding structural applications, such as superalloy turbine airfoils and works of art.

The investment casting process employs a mold produced by enclosing an expendable pattern with a refractory slurry that is then hardened. The pattern, usually made from wax or plastic, is subsequently removed (e.g., by melting, dissolving, or burning), creating the desired mold cavity. The expendable

patterns are themselves cast in a permanent pattern die. Ceramic cores can create internal passages within the casting.

*Key System Components.* Shell investment and solid investment processes are used in the production of investment castings (Horton, 1988). The two processes differ in the method of mold preparation, not in pattern preparation or pattern assembly. In the *shell investment process*, the pattern assembly is precoated, dipped in a coating slurry, and covered with granulated refractory until the shell is built up to desired thickness, usually less than 0.5 in. (20  $\mu\text{m}$ ); the thickness depends on the casting size and weight, cluster size, and type of ceramic and binder. As thin a shell as possible is specified to maximize mold permeability. Ceramic shell molds are used for the investment casting of carbon and alloy steels, stainless steels, heat-resistant alloys, and other alloys with melting points above 1100°C (2000°F).

The *ceramic material* used in shell investments is often silica, zircon (zirconium orthosilicate), an aluminum silicate, or alumina (Horton, 1988). *Silica glass* (fused silica) is desirable because it is readily available, but it has a high coefficient of thermal expansion and an abrupt phase transition, and it cannot be used in vacuum casting because the silica decomposes at low vapor pressures, leading to severe metal–mold reaction. *Zircon* is readily available, is resistant to wetting by molten metal, and has a high refractoriness. Its use is limited to prime coats though, because it is not available in large grain sizes. *Aluminum silicates*, such as mullite, can be manufactured to a range of pellet sizes and over a range of compositions. *Alumina* is more refractory than silica or mullite and is not very reactive with many metals.

The *binders* most often employed in shell investments are colloidal silica, ethyl silicate, and sodium silicate. *Colloidal silica* is an excellent general-purpose binder, and is the most widely used binder. Its primary disadvantage is that it is slow to dry. *Ethyl silicate* produces a bond between the refractory material that is very similar to that of colloidal silica. It dries much faster, but poses a fire hazard and is more expensive. Liquid *sodium silicate* forms a strong, glassy bond. The material is inexpensive but its refractoriness is poor, and the bond deteriorates in the presence of steam used to remove the wax pattern.

In the *solid investment process*, the pattern assembly is placed in a flask, which is filled with a refractory mold slurry. This slurry hardens in air, forming a solid mass in which the pattern assembly is encased. The types of bonding materials and refractories differ depending on the pouring temperature of the metal. For nonferrous alloys, pouring temperature is usually below 2000°F (1100°C). In these cases, *alpha gypsum* is commonly used as both the refractory and the binder, with other refractories such as silica added to improve mold permeability. The process is primarily used for making dental and jewelry castings.

For extremely limited production and for the development of production process parameters, investment mold patterns can be directly machined from an expendable material, such as plastic. For production-level investment casting, however, the patterns are produced by injecting wax or plastic into *permanent pattern molding dies*. The dimensional tolerance of these permanent dies must be closely controlled.

A mixture of paraffin and microcrystalline *wax* is widely used for making investment casting patterns (Horton, 1988). Waxes are strong, stiff, and provide adequate dimensional control during pattern making. They are easy to remove with pressurized saturated steam or elevated temperatures. *Plastic* patterns have several advantages compared with wax: higher strength, less subject to handling damage, can withstand automatic ejection from the pattern mold, and can reproduce thinner sections, finer definition, sharper corners, and better surface finish. But a major disadvantage is that certain plastics, such as polystyrene, expand during burnout and can crack ceramic shell molds.

Some investment castings require complex internal cavities (e.g., holes and air passages). For complicated shapes, the pattern-die *cores* are used to form portions of the pattern that cannot be withdrawn after the pattern is made. The cores must subsequently be dissolved or etched out from the casting.

As much *gating* as possible is included in the wax patterns. This allows use of standard methods of joining patterns together so that a number of investment castings can be produced during one pouring operation.

Investment casting is done in air and in vacuum. *Gravity pouring* fills the pouring basin from a ladle or directly from a furnace. This method requires low equipment investment, but highly skilled operators. In *pressure pouring* the molds are filled from the furnace with an assist from a pressurized gas to fill rapidly thin sections. With *vacuum-assisted pouring*, a vacuum pump evacuates air from a mold ahead of the stream of molten metal to minimize flow resistance. *Centrifugal casting* uses a spinning mold assembly to develop added pressure to fill the mold.

*Capabilities and Process Limitations.* Investment castings:

- Produce complex shapes that are difficult to make by other means
- Reproduce fine detail, high dimensional accuracy, and smooth surfaces requiring only minimal finishing
- Adapt to most metal alloys
- Allow control of metallurgical properties such as grain size and grain orientation

A tolerance of  $\pm 0.002$  in. (0.05 mm) can be held on investment castings for each inch in its maximum dimension; however, a tolerance of  $\pm 0.005$  in. (0.13 mm) is more typical (Horton, 1988). A surface finish of 125 min. (3 mm) can be readily achieved, and surface finishes as smooth as 30 to 40 min. (0.8 to 1.0 mm) can be produced with suitable process control.

The size and weight of castings that can be investment cast are usually limited by physical and economic considerations. Generally, the process can be applied cost-effectively to casting weighing up to 10 lb (4.5 kg); investment castings weighing 50 lb (22.5 kg) are not unusual, and castings as large as 1000 lb (450 kg) are feasible. The initial tooling costs of investment casting can be high.

## Structure-Change Processes

Structure-change processes alter the microstructure of a workpiece. These changes can be achieved through thermal treatment involving heating and cooling (quenching) under controlled conditions, sometimes in combination with mechanical forces, in order to effect desired solid-state phase transformations. These processes include those that diffuse selected species into a surface layer to modify its composition or to create a thin layer of material that does not increase the dimensions of the workpiece.

The two structure-change processes described here are representative examples. *Normalization of steel* is a process that changes bulk properties of a workpiece. *Laser surface hardening* of steel only changes its surface properties; it does not affect the bulk properties. Even though both examples relate to ferrous

materials, structure-change processes are used to impart desired properties to many material systems; e.g., age hardening of aluminum alloys. The references listed at the end of this section contain detailed information on structure-change processes.

## Normalizing Steel

*Description and Applications.* Normalizing is a heat-treating process that results in a relatively uniform steel microstructure. Essentially all the standard carbon steels can be normalized. The resulting phases and their size/distribution depend heavily on the carbon content of the steel. Normalization treatments are performed for a variety of reasons (Ruglic, 1991):

- Refine the dendritic grain structure remaining from casting
- Eliminate severe texture (and hence anisotropic properties) that results from forging and rolling operations
- Reduce residual stresses
- Improve the response of a steel to further processing, such as machining or surface hardening
- Improve mechanical properties by precipitating desirable phases

*Principle of Operation.* The steel workpiece must be heated sufficiently high to transform the entire structure to austenite, a face-centered cubic phase which essentially solutionizes all the carbon (at room temperature iron exists as ferrite, a body-centered cubic phase which has a very low carbon solubility). Diffusion-controlled solid-state phase transformations require time at temperature to occur. Therefore, the workpiece must be held at temperature long enough for austenite to dissolve the carbon.

The workpiece is then cooled slowly enough to avoid trapping the carbon in a supersaturated solution as the iron transforms back from austenite to ferrite. A time–temperature–transformation curve depicts which phase transformations will occur for different cooling gradients. A typical T-T-T curve is shown in Figure 13.2.11, which depicts the difference between a normalizing cool rate and that for annealing. For the normalization treatment to be successful, the regions in the microstructure with a carbon content of 0.8% carbon precipitate fine lamellae of ferrite and iron carbide ( $\text{Fe}_3\text{C}$ ) on cooling, known as pearlite. Those areas low in carbon content should precipitate ferrite grains during the initial phase of the cooling cycle, followed by pearlite precipitation. The regions high in carbon should precipitate iron carbide in the austenite grain boundaries, followed by pearlite precipitation (Ruglic, 1990).

The end result of normalization is a microstructure, and hence the mechanical properties characteristic of the composition of the steel (primarily governed by carbon content) as opposed to a microstructure that was principally shaped by its previous thermomechanical processing.

**FIGURE 13.2.11** Time–temperature–transformation curve for normalizing compared to annealing. (From ASM Handbook, Heat Treating, Vol. 4, 10th ed., ASM International, Metals Park, OH, 1991, 35. With permission.)

**Key System Components.** Conventional heat-treating furnaces are used for normalization, such as batch or continuous furnaces (Ruglic, 1991). The rate of heating is not critical. The furnaces must be able to heat the component to about 100°F (55°C) into the austenitizing region — this temperature depends on the composition of the steel.

Control of the cooling rate is critical. In the usual case, a workpiece can be removed from the furnace and allowed to air cool uniformly until the diffusion-controlled phase transformations are completed.

**Process Limitations.** The ability to normalize the microstructure of steel is governed by thermodynamics. Phase stability and kinetics of the phase transformations are crucial. But heat transfer considerations also play a major role. For instance, it may not be possible to achieve the desired cooling gradient in the center of a thick section, and hence the properties of such sections will not be uniform.

For complex shapes or for those workpieces having a high degree of residual stresses, some distortion will occur during the normalization process. The extent of distortion can be reduced by appropriate fixturing, but it cannot be eliminated. Hence, some tolerance allowance must be made.

### Laser Surface Hardening

**Description and Applications.** Laser surface hardening is used as an alternative to flame hardening and induction hardening ferrous materials. The rapid heating rate achievable by the laser minimizes part distortion and can impart surface hardness to low-carbon steels. The ability to locate the laser some distance from the workpiece can also be advantageous. The entire operation can be performed in air. This process is used to harden selected areas of machine components, such as gears, cylinders, bearings, and shafts.

Laser surface hardening imparts wear resistance and strength to the surface of a component without affecting its overall dimensions or changing its bulk properties. It is applied to selected areas which can be accessed by a laser beam. The process relies on rapid laser heating, followed by rapid quenching, to effect the necessary degree of hardening through phase transformation. The result is a very fine grain structure that is extremely hard. Typical case depth is a function of the composition of the ferrous material, but it will usually not exceed 0.1 in. (0.25 cm). For low- and medium-carbon steels, the case depth will range from 0.01 to 0.05 in. (0.03 to 0.13 cm), with the case depth increasing as the carbon content increases (Sandven, 1991).

**Principle of Operation.** An industrial laser rapidly heats a thin surface layer into the austenite phase region (austenite is a face-centered cubic allotropic phase of iron that has a high solubility for carbon). The interior of the workpiece is unaffected. When the laser beam is moved, the heated surface quickly cools. Consequently, the carbon does not have time to diffuse as the iron attempts to transform back to its ferrite (body-centered cubic) structure. The resulting microstructure is extremely hard since the trapped carbon atoms distort the iron crystal structure into a highly strained body-centered tetragonal form, known as martensite.

**Key System Components.** The majority of *industrial metalworking lasers* are either solid-state Nd:YAG or carbon dioxide type. Either pulsed or continuous mode can be used for surface treatment. The power output range for YAG lasers is 50 to 500 W. Carbon dioxide lasers are available in much higher power levels, up to 25 kW.

The surface to be hardened is usually *coated* to improve its ability to absorb laser radiation. A typical coating is manganese phosphate. *Paints* containing graphite, silicon, and carbon are also used. These coatings/paints can increase the absorption of laser energy to 80 to 90% (Sandven, 1991).

The output beam of the laser must be shaped and directed by an *optical system* to generate a laser spot of desired shape and size at the correct location on the workpiece surface. Reflective optical components are used since they are sturdy and easily adapted to an industrial environment.

**Process Parameters.** Many factors affect the end result of laser surface hardening. Important is the hardenability of the workpiece material which is affected by its composition and prior thermomechanical

history. For the laser process, the key parameters are beam power density, uniformity of the beam, and processing speed. Following are some general processing guidelines (Sandven, 1991).

- The range of usable power densities for laser surface hardening is 3200 W/in.<sup>2</sup> (500 W/cm<sup>2</sup>) to 32,000 W/in.<sup>2</sup> (5000 W/cm<sup>2</sup>) with beam dwell times ranging from 0.1 to 10 sec; higher power levels would melt the surface.
- Alloys with high hardenability can be processed at low speed with low power density to produce relatively thick cases.
- Alloys with low hardenability should be processed at high speed with high power density; the result is a shallow case.
- Beam configuration can be rectangular, square, or round; uniform energy density within the beam is very important.
- Maximum achievable surface temperature is proportional to the square root of the processing speed; thus doubling the beam power density requires the processing speed to be increased by a factor of four to maintain the equivalent maximum surface temperature.
- Smaller workpieces are not as effective a heat sink as larger workpieces, and hence self-quenching may have to be assisted by quenching media.

*Process Limitations.* The depth of hardness that can be practically achieved is limited by the surface melting point. Because of the high beam energy density, heat flow on complex-shaped surfaces, particularly those involving sharp corners or edges, can cause unexpected surface melting. Therefore, power density and process conditions must be carefully controlled.

It may be necessary to overlap passes of the laser beam, such as at the end of a complete pass around a cylinder. As a result, some tempering of the area already hardened occurs. The slower the processing speed, the greater the degree of tempering.

## Deformation Processes

Deformation processes change the shape of an object by forcing material to flow plastically from one shape into another shape without changing mass or composition (Table 13.2.15). The initial shape is usually simple. This shape is plastically deformed between tools or dies to obtain the final desired geometry, properties, and tolerances. A sequence of such processes is generally used to progressively form material. Deformation processes, along with casting and machining, have been the backbone of modern mass production.

In addition to shape change, forming processes alter the microstructure of the workpiece and can improve material properties. Deformation processes are normally considered when (Semiatin, 1988):

- Part geometry is moderately complex
- Component properties and structural integrity are important

**TABLE 13.2.15 Significant Factors in Modeling a Deformation Process**

Process Component	Characteristics
Input material	Flow stress; workability; surface condition
Output material	Geometry; mechanical properties; dimensional accuracy and tolerances; surface finish
Deformation zone	Deformation mechanics; stress state; temperature
Tooling	Material and geometry; surface conditions; temperature
Tool/material interface	Friction and lubrication; heat transfer
Process equipment	Speed and production rate; power range; precision

- Sufficient production volume can amortize tooling costs

Deformation processes can be classified (Semiatin, 1988) as bulk forming processes and sheet forming processes.

*Bulk forming* processes (e.g., rolling, extrusion, and forging) are characterized by

- Input material form is a billet, rod, or slab
- Workpiece undergoes a significant change in cross section during forming

*Sheet metal forming* processes (e.g., stretching, flanging, and drawing) are characterized by

- Input material is a sheet blank
- Workpiece is deformed into a complex three-dimensional form without appreciably changing the cross section

The key to attaining desired shape and properties is controlling metal deformation (Altan et al., 1983). The direction of the metal flow, the magnitude of the deformation, the rate of deformation, and the processing temperatures greatly affect the properties of the formed part. Design of the end product and the required deformation process consists of these steps:

- Predict metal flow by analyzing kinematic relationships (e.g., shape, velocities, strain rates, and strains) between the deformed and undeformed part configurations
- Establish producibility limits
- Select the process equipment and tooling capable of operating within the producibility limits

A bulk forming process (forging) and a sheet forming process (bending) are described below as representative examples of deformation processes. The references listed at the end of the section should be consulted for further information on these unit processes.

## Die Forging

### *Talyan Altan*

*Description and Applications.* Forging involves the controlled plastic deformation of metals into useful shapes (ASM, 1988c). Deformation may be accomplished by means of pressure, impact blows, or a combination. In order to reduce the flow stress, forging is usually accomplished at an elevated temperature. Forging refines the microstructure of a metal and can improve its mechanical properties, especially in preferred directions. Forging can also be used for other purposes, such as to consolidate powder preforms by welding grains, eliminate porosity in castings, break up long inclusions in forgings, and demolish the dendritic structure resulting from casting (Altan, 1988a).

Forgings are generally considered when strength, reliability, fracture toughness, and fatigue resistance are important. Forgings are used in critical, high-load applications, such as connecting rods, crankshafts, transmission shafts and gears, wheel spindles, and axles. Military and commercial aircraft are major users of forgings for numerous critical items, such as bulkheads, beams, shafts, landing gear cylinders

and struts, wheels, wing spars, and engine mounts. Similarly, jet engines depend on forgings for disks, blades, manifolds, and rings.

*Types of Forging Processes.* There are two broad categories of forging processes: closed-die forging and open-die forging. *Closed-die forging*, also known as *impression die forging*, employs precision-machined, matching die blocks to forge material to close dimensional tolerances. Large production runs are generally required to justify these expensive dies. During forging, the die cavity must be completely filled. In order to ensure this, a slight excess of material is forged. Consequently, as the dies close, the excess metal squirts out of the cavity in a thin ribbon of metal, called flashing, which must be trimmed.

*Isothermal forging* in heated superalloy dies minimizes the die quenching effect, preventing the rapid cooling of the workpiece in cold dies. This allows complete die fill and the achievement of close dimensional tolerances for difficult to process materials, such as superalloys.

*Open-die forgings* are the least refined in shape, being made with little or no tooling (Klare, 1988). These forgings are large, relatively simple shapes that are formed between simple dies in a large hydraulic press or power hammer. Examples are ship propeller shafts, rings, gun tubes, and pressure vessels. Since the workpiece is always larger than the tool, deformation is confined to a small portion of the workpiece at any point in time. The chief deformation mode is compression, accompanied by considerable spreading in the lateral directions.

*Key System Components.* There are two major classes of forging equipment as determined by their principle of operation: forging hammer, or drop hammer, which delivers rapid impact blows to the surface of the metal, and forging press, which subjects the metal to controlled compressive force. Each of these classes of forging equipment needs to be examined with respect to load and energy characteristics, its time-dependent characteristics, and its capability for producing parts to dimension with high accuracy.

*Forging hammers* generate force through a falling weight or ram (Altan, 1988b). These machines are energy restricted since the deformation results from dissipating the kinetic energy of the ram. The forging hammer is an inexpensive way to generate high forging loads. It also provides the shortest contact time under pressure, ranging from 1 to 10 msec. Hammers generally do not provide the forging accuracy obtainable in presses.

Forging presses are either mechanical or hydraulic (Altan, 1988c). *Mechanical forging presses* are stroke-restricted machines since the length of the press stroke and the available load at various positions of the stroke represent their capacity. Most mechanical presses utilize an eccentric crank to translate rotary motion into reciprocating linear motion of the press slide. The blow of the press is more like a squeeze than an impact of a hammer. Because of this, dies can be less massive and die life is longer than with a hammer. *Hydraulic presses* are load-restricted machines in which hydraulic pressure actuates a piston that squeezes the die blocks together. Full press load is available at any point during the stroke of the ram. A hydraulic press is relatively slow, resulting in longer process time; this may cause undesirable heat loss and die deterioration.

*Design Considerations.* Preform design is the most difficult and critical step in forging design. Proper preform design assures defect-free flow, complete die fill, and minimum flash loss. Although metal flow consists only of two basic types, extrusion (flow parallel to die motion) and upsetting (flow perpendicular to the direction of die motion), in most forgings both types of flow occur simultaneously, leading to a very complex flow field. An important step in understanding metal flow is to identify the neutral surfaces. Metal flows away from the neutral surface in a direction perpendicular to the die motion. Ideally, flow in the finishing step should be lateral toward the die cavity without additional shear at the die-workpiece interface. This type of flow minimizes forging load and die wear. A milestone in metalworking is the use of CAD in establishing the proper design for preforming and finishing dies in closed-die forging (Gegel and Malas, 1988). [Figure 13.2.12](#) illustrates the relationships between forging process variables and those of a forging press that must be understood in order to estimate process performance for a hot-forging operation.

**FIGURE 13.2.12** Relationships between process and machine variables in hot-forging processes conducted in presses. (From *ASM Handbook, Forming and Forging*, Vol. 14, 9th ed., ASM International, Metals Park, OH, 1988, 36. With permission.)

Designing a mechanical component that is to be made by forging together with the optimum geometry for the forging dies requires analysis of many factors (Altan, 1988a), including

- Design rules
- Workpiece material specification, and its critical temperatures
- Flow stress of the material at the process conditions (e.g., temperature, temperature gradient, strain rate, total strain)
- Workpiece volume and weight
- Frictional conditions in the die
- Flash dimensions
- Number of preforming steps and their configuration (flow field for the material)
- Load and energy requirements for each forging operation
- Equipment capability

In closed-die forging, it is particularly difficult to produce parts with sharp fillets, wide thin webs, and high ribs. Moreover, dies must be tapered to facilitate removal of the finished piece; draft allowance is approximately  $5^\circ$  for steel forgings (see [Table 13.2.16](#)).

**TABLE 13.2.16 Typical Forging Defects and Mitigation Strategies**

Defect	Description and Cause	Mitigation Strategy
Surface cracking	Fine cracks in the surface of the forging Possible causes: <ul style="list-style-type: none"> <li>• Excessive working of the surface at too low a temperature</li> <li>• Brittle or low melting phases in the grain boundaries</li> <li>• Cracking at the die parting line</li> </ul>	Increase the amount of preheating of the forging billet and forging die Change material specification Change furnace atmosphere to avoid diffusion of unwanted elements Increase the flash thickness Relocate the die parting line to a less critical location Stress relieve the forging prior to flash removal
Cold shut	Appears as a fold; occurs when two surfaces of metal fold against each other without welding Possible causes: <ul style="list-style-type: none"> <li>• Poor metal flow in the die</li> <li>• Excessive chilling during forging</li> <li>• Poor die lubrication</li> </ul>	Redesign forging die and/or forging preform to improve plastic flow of the metal during the forging operation Redesign the forging to avoid areas which are difficult to fill Increase the amount of preheating of the forging billet and forging die Improve die lubrication
Underfill	Incomplete forging in which all details are not produced Possible causes: <ul style="list-style-type: none"> <li>• Debris residue in die</li> <li>• Scale on forging billet</li> <li>• Billet too small to completely fill die</li> </ul>	Clean die thoroughly Completely descale the billet Redesign preform
Internal cracks	Cracks not visible from the surface, but detected during inspection and/or exposed during metal removal Possible causes: <ul style="list-style-type: none"> <li>• Scale embedded in the internal structure of the forging</li> <li>• High residual tensile stresses</li> </ul>	Completely descale the billet For open-die forgings, use concave dies Redesign for closed-die forging Use a hydraulic press and heated dies to avoid formation of excessive tensile stresses during forging

### Press-Brake Forming

*Description and Applications.* Press-brake forming is a process used for bending sheet metal; the workpiece is placed over an open die and then pressed into the die by a punch that is actuated by a ram known as a press brake (ASM, 1988b). The main advantages of press brakes are versatility, ease and speed with which new setups can be made, and low tooling costs.

Press-brake forming is widely used for producing shapes from ferrous and nonferrous metal sheet and plate. Although sheet or plate 0.250 in. (10 mm) thick or less is commonly formed, metals up to 1 in. (25 mm) thick are regularly formed in a press brake. The length of a sheet is limited only by the size of the press brake. Forming can be done at room or elevated temperature. Low-carbon steels, high-strength low-alloy steels, stainless steels, aluminum alloys, and copper alloys are commonly formed in a press brake. Press-brake forming is applicable to any metal that can be formed by other methods, such as press forming and roll forming.

Press-brake forming is considered for bending sheet metal parts when the production quantities are small, dimensional control is not critical, or the parts are relatively long. In contrast, press forming would be considered when production quantities are large, tolerances are tight, or parts are relatively small. Contour roll forming would be another option for high-rate production applications (ASM, 1988c).

*Principle of Operation.* Bending is a method of forming sheet metal by stressing a material beyond its yield strength while remaining below its ultimate strength so that cracking is avoided. In press-brake forming the tooling and setup are relatively simple. A workpiece is placed over a die, typically having a V-shape. The bend angle is determined by the distance the workpiece is pressed into the die by the

punch. The width of the die opening (top of the V) affects the force needed to bend the workpiece. The minimum width is determined by the thickness of the workpiece and the radius of the punch nose.

**Key System Components.** A *press brake* is basically a slow-speed punch press that has a long, relatively narrow bed and a ram mounted between end housings. Rams are mechanically or hydraulically actuated. [Figure 13.2.13](#) depicts a typical setup for press-brake forming.

**FIGURE 13.2.13** Typical setup for press-brake forming. (From *ASM Handbook, Forming and Forging*, Vol. 14, 9th ed., ASM International, Metals Park, OH, 1988, 533. With permission.)

V-bending dies and their corresponding punches are the tools most commonly used in press-brake forming. The width of the die opening is usually a minimum of eight times the sheet thickness.

**Process Parameters.** Capacities of commercial press brakes range from 8 to 2500 tons. Required capacity is governed by the size and bending characteristics of the work metal and by the type of bend to be made (ASM, 1988b).

The nose radius of the punch should not be less than the work-metal thickness for bending low-carbon steel, and must be increased as the formability of the workpiece material decreases. The radius of the V-bending die must be greater than the nose radius of the punch by an amount at least equal to the workpiece thickness to allow for the bottoming of the punch in the V.

It is preferable to orient a bend so that it is made across the rolling direction rather than parallel to it. Sharper bends can be made across the rolling direction without increasing the probability of cracking the material. If bends must be made in two or more directions, the workpiece should be oriented on the sheet layout such that none of the bends will be parallel to the rolling direction.

Springback after press-brake bending is considered only when close dimensional control is needed. It can be readily compensated for by overbending. Factors that affect springback include the mechanical properties of the work material, the ratio of the bend radius to stock thickness, the angle of bend, the method of bending, and the amount of compression in the bend zone. A greater amount of overbending is needed to correct for springback on small bend angles than on large bend angles.

**Capabilities.** The generally accepted tolerance for dimensions resulting from bending of metal sheet in the press brake is  $\pm 0.016$  in. ( $\pm 0.4$  mm) up to and including 0.125 in. (3 mm) thickness (ASM, 1988b). For heavier gauges, the tolerance must be increased accordingly. Achievable tolerances are influenced by the part design, stock tolerances, sheet metal blank preparation, the condition of the machine and its tooling, and operator skill.

**Design Factors.** In press-brake forming, as in other forming processes, the metal on the inside portion of the bend is compressed or shrunk, and the metal on the outside portion is stretched. This results in a strain gradient across the thickness of the workpiece in the area of the bend with tensile strain on the outside and compressive strain inside. These residual strains (and resulting stresses) can lead to distortion of the part under loading conditions, heating, or cooling.

The formability of metals decreases as the yield strength approaches the ultimate strength. In press-brake forming, as the yield strength of the work metal increases, power requirements and springback problems also increase, and the degree of bending that is practical decreases.

There are several factors which will make it difficult to establish or maintain accurate placement of a bend line in a press brake. Corrective action may require a design change or change in processing sequence.

- Bends or holes that are located in close proximity to the required bend line can cause the position of the bend line to wander.
- Notches and cutouts located directly on the bend line make it difficult to maintain an accurate bend location.
- Offset bends will shift location unless the distance between bends in the offset is at least six times the thickness of the workpiece material.

If multiple bends must be made on a workpiece, it may not be possible to avoid a bend that is parallel to the rolling direction. Depending on the degree of texture in the sheet and the anisotropy of the material, a change to a higher-strength material may be necessary to achieve the desired geometry.

## Consolidation Processes

Consolidation processes fuse smaller objects such as particles, filaments, or solid sections into a single solid part or component to achieve desired geometry, structure, and/or property. These processes use either mechanical, chemical, or thermal energy to bond the objects. Interaction between the material and the energy that produces the consolidation is a key feature of the process.

Consolidation processes are employed throughout manufacturing, from the initial production of the raw materials to final assembly. One group of processes involves the production of parts from powders of metals, ceramics, or composite mixtures. The resultant consolidated products are typically semifinished and require further processing. For instance, the consolidation of powders produces bar, rod, wire, plate, or sheet for upstream processes.

The consolidation of net shape composite structures (i.e., require minimal finishing work) is an increasingly important area. The design of the structural geometry, selection of material, and choice of consolidation processes all act together to provide the required level of performance. There are two types of matrix materials used: thermosetting and thermoplastic. The consolidation process of each of these types of resins is different. A unit process described in this section addresses the consolidation of composites using polymeric thermosetting resins.

An important family of consolidation processes includes welding and joining processes used to permanently assemble subcomponents. Historically, welding and joining processes are developed empirically and quickly evaluated for benefit in manufacturing applications, driven by the promise of significant potential benefits. The need for welding and joining is substantial since only monolithic parts can be made without joining. The ideal joint would be indistinguishable from the base material and inexpensive to produce (Eagar, 1993). However, experience indicates that no universal joining process exists that can entirely satisfy the wide range of application needs, and thus design engineers must select the most appropriate joining methods that meet requirements. Shielded metal-arc welding, the most widely-used welding process, is described in this section.

The unit processes described here are a representative sample of the types most likely to be encountered. The references listed at the end of the section should be consulted for detailed information on these unit processes.

### **Polymer Composite Consolidation**

*Weiping Wang, Alan Ridilla, and Matthew Buczek*

A composite material consists of two or more discrete materials whose combination results in enhanced properties. In its simplest form, it consists of a reinforcement phase, usually of high modulus and strength, surrounded by a matrix phase. The properties of the reinforcement, its arrangement, and volume fraction typically define the principal mechanical properties of a composite material. The matrix keeps the fibers in the correct orientation and transfers loads to the fibers.

Continuous-fiber-reinforced materials offer the highest specific strengths and moduli among engineering materials. For example, a carbon fiber/epoxy structural part in tensile loading has only about 20% of the weight of a steel structure of equal stiffness. Composite parts can integrate component piece parts, such as molded-in rib stiffeners, without the need for subsequent assembly operations and fasteners.

*Description and Applications.* There are many types of polymer composites in use. Composites are usually identified by their fiber material and matrix material. Fiber materials are necessarily strong, stable materials that can be processed into fiber formats. Typical fibers are glass, graphite/carbon, aramid, and boron. *Glass* fibers represent the largest volume usage since they have excellent properties and are low cost. *Graphite/carbon* fibers are widely used for advanced composite applications in which stiffness and high performance are critical. These fibers are also expensive. *Aramid* fibers, a type of polyamide, have proved useful in applications where its performance in axial tension can be exploited without incurring too severe a penalty by the material's poor performance under compressive loading. *Boron* filaments have high strength and high modulus, but most applications requiring high performance, such as military aircraft structures, are now using carbon fibers.

Low-cost *polyester* resins are the most widely used matrix material for the general composite industry; the majority of these application use glass as the fiber. Many applications are found in the chemical process, construction, and marine industry. The most widely used polymers are *epoxy* resins, which are used with carbon, aramid, and boron fibers for many advanced applications, such as in aircraft structure and rocket motor fuel tanks. *Polyimides* are polymer resins that provide more temperature performance than is possible from the epoxy-based material, and these are used in advanced aircraft structures and jet engine components where heating of the structure will occur.

*Principle of Operation.* Each of the constituent materials in advanced composites acts synergistically to provide aggregate properties that are superior to the materials individually. The functional effectiveness

of composites is principally due to the anisotropy of the materials and the laminate concept, where materials are bonded together in multiple layers. This allows the properties to be tailored to the applied load so that the structure can be theoretically more efficient than if isotropic materials were used. The reinforcements come in a variety of formats. Unidirectional tapes with all fibers along a common axis, woven fabrics constructed with fibers along both axes in the  $x$ - $y$  plane, and multidimensional architectures with reinforcements in more than one axial direction are just a few of the available formats.

Consolidation in composites can be considered to occur at two levels: the fibers are infiltrated with the matrix to form a lamina or ply, and the individual laminae are consolidated together to form the final structure. In the prepreg process, these two levels are distinctly separated, since the fiber/matrix consolidation process forms the prepreg, which is then laid up to form the laminate or final component. In other processes, such as resin transfer molding, fiber/matrix infiltration and the consolidation of the final part are done in a single stage. Single-stage consolidation processes are attractive because they eliminate the additional cost associated with prepreg production; however, two-stage consolidation processes have major advantages that often outweigh the benefits of single-stage consolidation. These include flexibility in part geometry, high fiber content, excellent fiber wet-out, and better control of fiber volume fraction distribution. Because of these advantages, prepreg processing is firmly entrenched in high-value products, such as aerospace applications, in spite of its high cost.

*Fabrication Methods.* Typical steps in manufacturing continuous-fiber composites involve *preform fabrication* and consolidation/curing (Advani, 1994). Preform fabrication creates the structure by positioning material close to the final part shape (Table 13.2.17). The material comes in either the *dry fiber* (without resin) form or with resin included, called prepreg. Dry fibers are used in filament winding, weaving, braiding, and pultrusion. The resin can be introduced in the operation or downstream molding. *Prepreg*, at a higher material cost, eliminates the step of resin addition and provides the adhesion to hold the material together. Consolidation/curing involves compacting the preform to remove entrapped air, volatiles, and excess resins while developing the structural properties by increasing the polymer chain length and cross-linking.

*Process Parameters.* Thermosetting polymeric materials will not soften and flow upon reheating after polymerization because of the formation of a cross-linked polymer network. Hence, thermosetting polymer matrices must be cured *in situ* with the fibers to form the composite structure. The goals of a successful cure are good consolidation with low porosity and high conversion of initial monomeric constituents to polymer.

The challenge of the cure process is to manage the interactions of temperature distribution, degree of cure, laminate thickness, and void content by manipulating the applied temperature, pressure (or displacement), and vacuum. Temperature must be controlled so that resin temperature stays within limits. Both the duration and the magnitude of pressure application are important as excessive resin flow results in a resin-starved laminate. Similarly, pressure application too soon in the process can entrap volatiles in the material. Materials can also exhibit lot-to-lot variability. The problem is further complicated when processing a complex-shaped part or multiple parts of different geometry.

Composite cure processes are typically performed in an autoclave or in a heated press. An *autoclave* is essentially a heated pressure vessel. Nitrogen gas is normally used for pressurization. The temperature, pressure, and vacuum are controlled vs. time to effect the cure. Recent advancements in *intelligent processing* use sensors to determine the state of cure in real time, and make appropriate control adjustments to optimize the cure cycle (NRC, 1995). Figure 13.2.14, which plots data from an actual implementation, depicts the potential that intelligent processing has in reducing autoclave processing time and cost.

*Press molding* uses a high-pressure press and matched metal tools to form a part. The main components of a press-molding system include the tools, the ram, and the heated platens. Again, release materials must be applied to the tools to avoid laminate adhesion. Advantages of press molding include improved surface finish (since both sides are tooled) and the elimination of the vacuum bagging systems. However, the pressure inside the mold is not necessarily uniform and volatiles are not easily removed. Hence,

**TABLE 13.2.17 Methods of Composite Preform Fabrication**

Method	Description	Application
Weaving	Process of interlacing yarns to form a stable fabric construction that is flexible Less frequent interlacing results in better composite strength	Closely conforms to surfaces with compound curvature
Braiding	Intertwines parallel strands of fiber A tubular braid consists of two sets of yarn which are intertwined in “maypole dance” fashion; produced with varying diameter or circumferential size	Sporting equipment Good torsional stability for composite shafts and couplings Geometric versatility and manufacturing simplicity
Pultrusion	Reinforcing fibers pulled from a series of creels through a resin impregnating tank; preformed to the shape of the profile to be produced; enters a heated die and is cured to final shape	Produce constant cross-section pieces at high production rates
Filament winding	Pulling roving (unlisted bundles of fibers) over a mandrel by rotating the mandrel about a spindle axis; can cure on the mandrel	Cylindrical parts Can be low cost
Tube rolling	Material cut from prepreg tapes and laid on a flat surface; plies of different orientations joined together; a cylindrical mandrel is rolled on the material; curing is typically done on the mandrel	Low-cost method for making tubular structures or tapered tubes, e.g., golf shafts
Manual layup	Plies of different fiber orientations are cut from flat sheets of the prepreg material and laid up on a tool; bagging materials are applied and sealed to the tool for subsequent consolidation Flexible in producing complicated features at low start-up/tooling cost; building a curved, variable-thickness part can be complicated	Most common method used in the aerospace industry
Automatic tape layup	Computer-controlled machine tools or robots with a material delivery system • Automated tape layup machine uses prepreg tape, typically 3 to 12 in. wide, suitable for large surface of gentle contours • Fiber placement employs multiple tows for more complex surfaces	Provides lower cost and variability over manual layup, but requires higher capital investment

**FIGURE 13.2.14** Intelligent processing of composites. (From NRC, *Expanding the Vision of Sensor Materials*, NMAB-470, National Academy Press, Washington, D.C., 1995, 39. With permission.)

press molding is generally suitable for composite systems which do not generate a significant amount of volatiles.

### Shielded-Metal Arc Welding

*Description and Applications.* Bonding is achieved in fusion welding by interposing a liquid of substantially similar composition as the base metal between the surfaces to be joined (Eagar, 1993). The need for welding and joining is substantial since only monolithic parts can be made without joining. Traditional welding processes have unique advantages, which make them the processes of choice for a large number of applications. For example, in the fabrication of heavy structures, arc welding will dominate other assembly processes because of the inherent flexibility and economy of welding.

*Principle of Operation.* In the majority of arc-welding methods, the workpiece is made part of the electric welding circuit, which has as its power source a welding generator or transformer. To start a weld, an arc is struck by touching the workpiece with the tip of the electrode. The welder guides the electrode by hand in welding a joint, and controls its direction and traveling speed. The welder maintains arc voltage by controlling arc length (the distance between the end of the electrode and the work surface). Because an electric arc is one of the hottest sources of heat, melting occurs instantaneously as the arc touches the metal. Arc welding is a highly popular process because of its flexibility and relatively low cost (ASM, 1993).

In shielded-metal arc welding, an arc is struck between the workpiece and a covered (or coated) metal electrode. Filler metal is provided by the consumable electrode. Combustion and decomposition of the electrode covering from the heat of the welding arc produce a gaseous shield that excludes the oxygen and nitrogen in the atmosphere from the weld area; these gases would otherwise cause excessive porosity and poor ductility in the weld. Welds by this method are of very high quality (Juers, 1993). [Figure 13.2.15](#) depicts the components of the shielded-metal arc welding process.

**FIGURE 13.2.15** Shielded-metal arc-welding process. (From *ASM Handbook, Welding, Brazing, and Soldering*, Vol. 6, 10th ed., ASM International, Metals Park, OH, 1993, 175. With permission.)

*Key System Components.* For shielded-metal arc welding, the metallurgical properties of a weld depend greatly on the type of electrode and its covering. The *electrode coverings* contain shielding gas formers that exclude atmospheric gases from the weld area. Electrode coverings offer additional capabilities (Juers, 1993):

- Deoxidizers and nitrogen absorbers to purify the depositing metal
- Slag formers to protect the weld from oxidation
- Ionizing elements to stabilize the arc
- Alloying elements to produce higher-strength welds
- Iron powder to increase metal deposition rate

Selection of the proper electrode is based on many considerations (Juers, 1993):

- Base metal strength
- Base metal composition
- Welding attitude (position)
- Welding current
- Joint design and fit
- Base metal thickness and shape
- Service conditions
- Production efficiency and conditions

Many types and sizes of *power supplies* are used. Supplies can be either direct current (DC) or alternating current (AC) types; combination AC/DC power supplies are widely used. In general, power supplies are required that produce controllable levels of constant-current output. The rate of metal deposition is determined by the output current from the power supply.

*Capabilities.* Shielded-metal arc welding is the most widely used welding process for joining metal parts, principally because of its versatility. Also, the welding equipment is less complex, more portable, and less costly than for other arc-welding processes.

Shielded-metal arc welding is generally very useful in joining components of complex structural assemblies. Joints in virtually any position that can be reached with an electrode can be welded, even if directly overhead. Joints in blind areas can be welded using bent electrodes. Welding in positions other than flat require the use of manipulative techniques and electrodes that cause faster freezing of the molten metal to counteract gravity. Shielded-metal arc welding can be done indoors or outdoors.

Metals welded most easily by the shielded-metal arc process are carbon and low-alloy steels, stainless steels, and heat-resistant alloys. Cast iron and high-strength steels can also be welded but preheating and postheating may be required. Shielded-metal arc-welding electrode materials are available for matching the properties of most base metals; thus, the properties of a joint can match those of the metals joined.

*Design Considerations.* Joint design (shape and dimension) is determined by the design of the work-piece, metallurgical considerations, and established codes or specifications.

Welds should preferably be located away from areas of maximum stress. Poorly placed welds can result in undesirable, and unplanned, stress concentrations that can cause early failure of the joint.

Poor joint fit-up increases welding time and is often the cause of poor welds.

*Process Limitations.* Metals with a low melting point, such as zinc, lead, and tin, cannot be welded by electric arc methods.

Limitations of shielded-metal arc welding compared with other arc-welding methods are related to metal deposition rate and deposition efficiency. Consumable electrodes have a fixed length, usually 18 in. (460 mm), and hence welding must be stopped periodically to replace the electrode. Another limitation is the requirement to remove the slag covering that forms on the weld after each welding pass.

There is a minimum gauge of sheet that can be successfully welded without burn-through. Generally 0.060 in. (1.5 mm) is the minimum practical sheet thickness for low-carbon steel sheet that can be welded by a welder possessing average skill (Juers, 1993).

Special techniques are required when welding pieces of unequal thickness because of their different heat dissipation characteristics. Solutions include

- Placing a copper backing plate against the thinner section to match the heat dissipation from the thick section
- Redesigning the component so that the thick and thin sections taper at the joint to approximately the same size

Distortion is unavoidable in welding because of residual stresses that arise from nonuniform heating and cooling. Various procedures can be used to minimize distortion, such as clamping the workpieces. But straightening of the workpiece may be required to achieve the required dimensional accuracy.

## Mechanical Assembly

### *S. H. Cho*

Total labor involved in the assembly processes in the U.S. varies from 20% (farm machinery) to almost 60% (telecommunications equipment). On average, assembly tasks occupy 53% of manufacturing time, and 10 to 30% of total production cost of most industrial products. Use of improved assembly methods and technologies is essential to reduce overall manufacturing costs.

### Assembly Methods and Systems

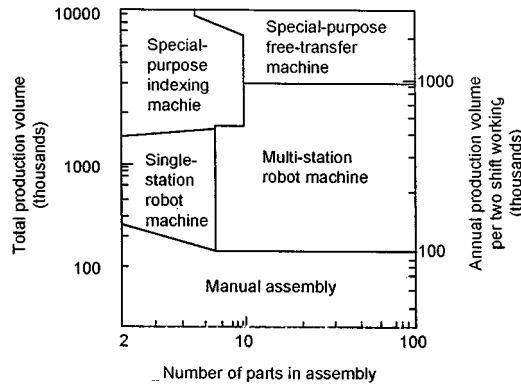

*Assembly systems* are classified in several different ways (Table 13.2.18). Figure 13.2.16 indicates the types of automated systems that could be cost-effective based on assembly part count and production volume.

Generally, *automatic assembly systems* consist of three major components:

- *Transfer system* to move work carriers with in-process subassemblies between workstations;
- *Parts feeding device* to supply parts to be assembled into the appropriate position, where the parts are loaded by the handling/placing mechanism;
- *Parts handling/placing mechanisms* to pick parts and perform assigned assembly tasks such as placing, inserting, and screwing.

**TABLE 13.2.18 Classification of Assembly Systems**

Type of Assembly System	Classification Basis	Description
Manual	Level of automation	Assembly tasks completed manually
Automatic	Level of automation	Adopts mechanized devices or industrial robots with supplementary equipment for handling and assembling parts
Semiautomatic system	Level of automation	Manual workers and mechanized devices cooperate to complete assembly tasks
Cell-type system	Configuration	Very flexible integrated assembly workstation; assembly completed by various equipment, such as robots or pick-and-place units, parts feeders, parts tray, magazines, automatic tool changer, and auxiliary jig/fixtures
Line-type system	Configuration	Assembly tasks divided into subtasks which are completed at workstations connected by transfer systems; handles large parts, cycle-time variation, and gripper change
Dedicated system	Degree of flexibility	Not flexible — can assemble only one product of a single model; generally economical for large production volumes
Flexible system	Degree of flexibility	Accommodates different products; economical for medium-size and mixed-model production

**FIGURE 13.2.16** Conditions for economic application of various assembly systems. (Courtesy of S. H. Cho.)

The *transfer system* can be continuous or intermittent according to the transfer method. In the *intermittent transfer system*, assembly tasks in a workstation are performed during a stationary period of the work carriers, which are transferred to the subsequent workstation after completion of the assembly tasks. *Continuous transfer systems* have a problem of not being able to assure positioning accuracy between an in-process subassembly and the tools of a workstation; thus, the intermittent type is usually used (Boothroyd, 1992).

There are two modes of *intermittent transfer*: in-line and rotary. For the *in-line* mechanisms, the walking beam, the shunting work carrier, and the chain-driven work carrier are commonly used. The *rotary* type employs mechanisms such as rack and pinion, ratchet and pawl, Geneva mechanism, and mechanical cam drives. Currently, free-transfer conveyors with stopping and positioning mechanisms are widely used in flexible assembly lines.

Most *feeding systems* have devices to orient parts supplied by the following means (Yeong and Vries, 1994):

- *Bulk supply*, for parts that are easily separated, fed, and oriented automatically. Bulk supply usually adopts various part feeders, e.g., vibratory bowl feeders and various nonvibratory mechanical feeders for small parts. These feeders usually only handle one type of part and cannot be applied to assembly systems which require flexible part-feeding devices.

- *Organized supply* uses special pallets such as a kit or a magazine for parts that cannot easily be separated, fed, and oriented.

*Parts-handling/placing mechanisms* include pick-and-place units and various types of industrial robots. To load and assemble parts, the mechanism usually employs various assembly wrists: jaw-type gripper, vacuum suction pad, magnetic chuck, screwdriver, nut runner, and others. A number of different wrists are required when automatically assembling different parts in a workstation. To accommodate this assembly situation, a multifunctional gripper, a tool-changing system, and a universal gripper have been developed and widely used in robotic assembly systems.

### Selection of Assembly Systems

The placement of a part in its assembled position and part mating impose tight constraints on the positioning mechanism and on part properties such as clearances and geometry. These constraints are more severe for assembly systems mating a variety of precision products that must adapt to frequent design changes. The assembly systems of this type must possess the adaptability to changing assembly environments, thus requiring *flexible automatic assembly* (Boothroyd, 1984).

A typical *flexible robotic assembly system* uses an industrial robot for part handling, part positioning, and part mating. These systems are limited by positioning and orientation misalignment caused by the low positioning accuracy of robots, uncertainty in part handling, and variation in the location of parts.

Various approaches are available that take into consideration uncertainty in orientation and parts properties variation. Figure 13.2.17 depicts various types of assembly wrists that are in use. In general, wrists can be classified into three basic configurations:

- Passive accommodation;
- Active accommodation;
- Passive-active accommodation.

There are two types of *passive wrist methods*:

- Wrist accommodates misalignments by deforming its structure elastically under the influence of the contact forces generated during the assembly of the misaligned parts. A *mechanically compliant structure* is needed for either the robot wrist or the assembly worktable, which can be deformable according to the reaction force acting on the mating parts. Remote center compliant wrist is one of such typical wrists; this method usually requires part chamfering (Cho et al., 1987).
- Wrist corrects misalignment by *applying external forces* or torques to the misaligned parts in a prescribed manner or a random way. For instance, a vibratory wrist utilizes pneumatic actuators controlled by a pulse width modulation controller to generate desirable vibration; this method does not require part chamfering.

*Active wrist methods* employ sensor-controlled wrists and compensate misalignments by controlling the fine motion of the assembly wrist or the work table based upon sensory feedback. Advances have been made in the area of sensing technique, gripper and actuating mechanism design, and the related control algorithms. Sensors for these wrists are needed prior to contact (vision, range, displacement, proximity), during contact (touch, slip), and after contact (force, moment). Based upon the force sensor signals and the associated algorithms, the wrist motion can be corrected to reduce misalignment.

The *passive-active accommodation method* is achieved by combination of the “passive and active” techniques. The basic strategy is that the part mating is continued within some allowable forced moments, while beyond this the insertion method is switched from the passive to active to reduce the mating force by using sensors with compliant structures.

The *sensor-based assembly* is similar to the method employing the active wrist. Both rely on sensory information for fine-motion control. The principal difference is that the former utilizes robot motion, while the latter relies on wrist motion.

FIGURE 13.2.17 Various assembly wrists. (Courtesy of S. H. Cho.)

Reaction forces (*force/torque information*) that occur during part mating can represent the status of the contact between mating parts. Among the approaches are pattern classifiers that determine the contact state at which the assembly parts are contacting each other, position error recovery via fuzzy logic, heuristic search with fuzzy pattern matching, and learning of nonlinear compliance using neural network.

*Visual/optical information* is critical to compensate for positioning and orientation error occurring due to misalignment. Visual information is often combined with other data, such as force/torque, pressure, and displacement, because a rather longer time is required for image processing, object recognition and error calculation and because visual information is sensitive to external environmental conditions such as illumination.

### Assembly Line

An assembly line usually consists of a set of workstations that perform distinct tasks linked together by a transfer mechanism. Each task is an assembly operation, while each workstation represents a location along the line where the tasks are processed. A buffer storage is placed between workstations for reducing the effect of a workstation failure on the throughput.

*Line balancing* is essential for designing a cost-effective assembly system (Groover, 1980). The time required for the completion of a task is known as the process time, while the sum of the process times

of the tasks assigned to a station is the station time. The total task processing times for assembling all the parts is the work content. When *assembly sequences* are generated without considering line balancing, the sequences may not guarantee the minimum number of workstations. Therefore, line balancing must be concurrently considered in defining the assembly sequences.

**Design for Assembly**

Approximately 80% of manufacturing cost is determined at the conceptual design stage. Design for assembly (DFA) is crucial during early design. The objective of the DFA is to facilitate the manufacturing and assembly of a product. DFA applies to all the assembly operations, such as parts feeding, separating, orienting, handling, and insertion for automatic or manual assembly (Ghosh and Gagnon, 1989).

DFA is directed toward:

- Reducing the number of parts by modularization;
- Easing feeding and minimizing reorientation;
- Easing insertion by self-aligning, self-locating, elimination of part interference, and efficient fastening.

*Axiomatic DFA* uses design guidelines based on experience of product designs and assembly operations. *Procedural DFA* evaluates the design efficiency based upon the production cost.

Figure 13.2.18 shows results that were obtained using DFA rules to evaluate part designs in consideration of feeding and insertion. Such analysis has great potential in improving assembly operations.

operation	original design	redesign	remark
feeding			make symmetry
			make symmetry
			eliminate tangling
			eliminate shingling
			eliminate jamming
			eliminate nesting
handling			make easy to grip
			make easy to grip
			make easy to orient
insertion			provide chamfer
			secure from misalignment
			keep the orientation
			avoid flexible parts

## Material Handling

*Ira Pence*

Material handling provides the right amount of all the required materials at the right place and time to support manufacturing. Properly designed, the material-handling system provides for the acquisition, transportation, and delivery of material such that the minimum cost is incurred considering capital, labor, and expenses. It focuses on obtaining material and supplies, moving them between process steps, and delivering the finished product to the customer. Figure 13.2.19 depicts the elements of a modern materials-handling system which reaches beyond the factory floor, serving as an integrating force for production operations.

**FIGURE 13.2.19** Modern material-handling system. (Courtesy of J. Lee.)

The material-handling system should be analyzed as a single entity so trade-offs in expense in various elements can be made to minimize the total cost. Often, however, the activities are broken into purchasing, transportation, warehousing, and distribution functions which operate independently. Such divisions are arbitrary because the material-handling system is an unbroken chain of activities that start when the suppliers complete their last value-added operation and extend until the product is delivered. Minimum-

cost material handling will not be achieved if the partitioning of material flow into subelements leads to optimization of each subelement at the expense of the entire system.

Planning is crucial to the design of a smoothly functioning materials operation. Planning should be consistent with the strategic plan for the entire manufacturing operation. In formulating the plan, a realistic assessment of the problems and opportunities associated with arranging, controlling, and implementing the material flow must be used. Specific tactics, such as just-in-time delivery, should support the strategic plan. Expensive automation should not be used unless the volume and stability of the product justify its use.

### Logistics

The movement of material in a manufacturing enterprise is usually broken into two broad categories, inside the plant and external to it. External movement is generally referred to as “logistics,” while the internal flow is known by many different names. Material movement considered logistics is generally marked by a wide geographic scope, diversity of equipment and technology, and some uncertainty in delivery time. But the basic goals are identical to in-plant movement and most of the analysis tools are applicable to both categories.

For large manufacturing enterprises the number of individual components involved in the production of the product, often referred to as SKUs (stock keeping units), can be very large. In the past, it was helpful to treat items of similar size, weight, storage requirements, and delivery times as a single commodity. This simplified manual analysis and was sometimes done by computer programs that analyze logistical information. However, current computer systems make it practical to treat each item individually.

### Basic Elements

The basic activities associated with material handling are *moving*, *storing*, and *controlling* material. These activities are interrelated with production scheduling and information must flow both ways.

Movement may be over short distances, as from one machining center to another, or long, from one plant to another. In all cases the basic information that must accompany the move includes the part identity, timing, quantity, source, and destination. Each move should be planned and scheduled, taking into account the speed of the basic mechanism as well as allowance for loading, unloading, logging, counting, etc.

Movement can be continuous or in batches, synchronous or asynchronous, horizontal or vertical. Each move should be examined for the characteristics of urgency, safety, size, weight, etc. before selecting the technology to be used to perform the move. Singular instances should be accommodated in the most expeditious manner, and repetitive moves must be made in the most efficient and effective manner.

One of the basic tenets of material handling is to retain *control* of the material. Inventory control generally maintains up-to-date records on the quantity and location of material on hand. However, in a *virtual warehouse*, it is important to know what material has been ordered and the status. Control includes procedures and equipment to properly handle the material.

The *storage* of material should be minimized. Materials are typically stored to compensate for uncertainty in delivery systems and to allow ordering of economic quantities.

Occasionally unexpected changes in production will result in delaying the release of material to the factory floor and that material must be stored until needed. *Just-in-time delivery*, where parts are delivered directly from local suppliers to the assembly line several times a day, has been proved in several industries. Thus, the need for storage due to uncertainty of delivery has been reduced. At the same time, global sourcing has increased. As supply lines lengthen, the uncertainty of delivery increases. The more complex the supply system, the more likely the occurrence of an unexpected delay. In designing a storage system, the trade-off of higher transportation cost but less inventory vs. volume discounts on purchases and transportation, but with storage costs, must be evaluated.

## Further Information

The Material Handling Industry produces two catalogs each year. One provides information on the publications available from the MHI, including all the educational material; standards and specifications; operating, maintenance, and safety manuals; and reference works. The other provides a directory of member companies and the products they manufacture. Both are available from the MHI Literature Department (704) 522-8644; FAX (704) 522-7826.

## Case Study: Manufacturing and Inspection of Precision Recirculating Ballscrews

*Toskiaki Yamaguchi, Yashitsugu Taketomi, and Carl J. Kempf*

The precision and quality of the components of mechanical devices used in both industrial and consumer products must meet high performance and durability requirements. The manufacturing challenges that apply to ballscrews, in general, are representative of other components such as gears, shafts, and bearings. This case study on precision ballscrews illustrates how the different unit manufacturing processes presented in this chapter apply to a particular application, and how design and manufacturing engineering decisions are affected by quality and cost considerations.

Many of the processing steps and fundamental techniques discussed in this case apply to the manufacture of many other precision components. The case study also illustrates the rationale for continuously improving production processes and discusses strategies for improvement that benefit from past experience.

### Overview of Ballscrew Design and Manufacturing Considerations

Ballscrews convert rotary motion into linear motion. Ballscrews have low friction compared with standard leadscrews, and have enabled precise control of mechanical systems at a relatively low cost. They are used extensively in production machinery, such as milling machines, and are being applied in other fields, such as robotics, inspection equipment, and office automation equipment.

The key components of a ballscrew system consist of a screw shaft with a spiral groove, a nut with a corresponding spiral groove that rides along the shaft, and balls which are captured between the shaft and the nut. A recirculation tube provides a return path for the balls from the end of the nut. Components in this assembly are typically made from steel alloys, chosen to provide a good combination of toughness, surface hardness, and ease of manufacture.

Ballscrews are applied in a variety of ways, but the most common configuration is one in which a rotational input of the shaft imparts a translational motion to the nut. The shaft is normally supported by rotating bearings at both ends, and the translating element attached to the nut is supported by linear guide bearings. Ballscrews range in size from very small units with a shaft diameter on the order of 0.08 in. (2 mm) and a length of about 4 in. (100 mm) to very large units with a shaft diameter on the order of 12 in. (300 mm) and a length of up to 50 ft (16 m). Key dimensional features which are controlled to a high degree of precision for an assembled ballscrew system are shown in [Figure 13.2.20](#).

The main factors in ballscrew performance are accuracy and lifetime. *Accuracy* is determined primarily by the precision of the screw lead, i.e., the linear displacement of the nut which is produced by rotary displacement of the shaft. The measurements used to assess the *precision* of the lead are discussed below. To obtain a *long lifetime*, the shaft must have high surface hardness in order to withstand loads at the shaft/ball and nut/ball interfaces. Since ballscrews may be subject to a variety of loading conditions, the ballscrew must possess good impact strength and toughness.

Secondary design factors include low audible noise, low static and dynamic friction, low friction variation, minimal backlash, high mechanical stiffness, and resistance to dirt and contaminants. Ballscrews are often used in specialized applications, such as operation in vacuum or ultraclean environments, in corrosive or dirty environments, in a thermally controlled environment, and in environments where vibrations must be minimized. To meet these demands, basic ballscrew designs are adapted to

FIGURE 13.2.20 Key ballscrew dimensions. (Courtesy of T. Yamaguchi, Y. Taketomi, and C. J. Kempf.)

use special materials, surface treatments, and to provide features such as hollow shafts for coolant flow or damping materials.

Major steps in production and assembly of traditional ground ballscrews are summarized as a flowchart in Figure 13.2.21.

### Initial Machining Operations

A lathe is used to establish the outer diameter of the shaft and cut the groove. In both operations, an allowance is made for material that will be removed in the final grinding operations. For short shafts, the support is provided from the shaft centers and a single cutting tool can be used with multiple passes to produce the desired outside diameter and groove. For long ballscrews, the lateral deflection of the shaft during cutting operations is significant and workpiece supports are necessary to prevent deflection of the shaft.

For long ballscrews, the total processing time can become extremely long using multiple passes with a single-point cutting tool. In such cases, a multiple-point tool that can remove more material on a single cutting pass is more efficient to use. But a multipoint cutter requires more time for setup and adjustment. Thus, there is an economic trade-off between single-point and multipoint cutting techniques.

Because of subsequent heat-treat operations, the shaft will undergo dimensional changes. The design must allow for these dimensional changes. This is an area in which production experience is critical. Statistical analysis of previous manufacturing results, together with modeling of material behavior, is critical to continued design and process improvement.

### Surface Treatments

In order to withstand the loads at contact points, a very high surface hardness is necessary. A surface hardness of Rockwell C 58-62 with a depth on the order of 0.8 to 1.2 mm is required. For short ballscrews, *carburization* is used to develop the necessary surface hardness. For longer shafts, carburization is impractical because of the size of carburizing furnaces. In this case, an induction hardening process is used.

Electrically heated gas furnaces are used in the carburizing process. The immersion in the carburizing furnace is followed by quenching and tempering. During carburizing, key parameters such as temperature and gas concentrations are continuously monitored and adjusted by a process control system. Because high hardness is needed only in the ball groove, areas of the shaft and nut that will be subject to subsequent machining operations are coated before carburizing. This coating, which is applied like paint, prevents the diffusion of carbon into the material surface.

For longer shafts, a different steel is chosen and an induction hardening process is used. The general trend within the industry is toward induction hardening since it has the advantage of being a continuous process. When using induction hardening, single shafts can be processed immediately after machining. Induction hardening machines require less initial capital than for a carburizing system.

FIGURE 13.2.21 Ballscrew processing flowchart. (Courtesy of T. Yamaguchi, Y. Taketomi, and C. J. Kempf.)

The shaft undergoes dimensional changes as a result of the surface heating, and a *straightening* operation is necessary. Prior to straightening, the shaft is chilled in a carefully controlled manner to sub-zero temperatures to ensure that the solid-state transformations are completed; the result is a more stable microstructure. For straightening, a *specialized press* is used to measure automatically the deviation from perfect straightness; it automatically applies loads along the shaft as necessary to restore the shaft to near-perfect straightness.

### Grinding and Finishing Operations

After surface treatment, chilling, and straightening, the outside diameter of the shaft is ground to the final dimensions. Except for very short ballscrews, the grinding cutting forces will cause lateral deflection of the shaft, and thus the centers in the shaft ends cannot be used as datums for final machining operations. Consequently, the outside diameter of the shaft is ground to precise tolerances. Although the outer

diameter of the shaft is not a functional part of the finished ballscrew, it is used as a datum surface when the final grinding of the shaft groove is performed.

Grinding of the shaft can be done on either centerless grinders or cylindrical grinders. Since centerless grinders take a long time to set up, they are generally used for large production runs of shafts having the same diameter. For the case of cylindrical grinders, the shaft is supported at the centers in the shaft ends as well as at workpiece supports along the length of the shaft. By adjusting the work rests, minor variations in taper and bending of the shafts can be corrected. This processing step requires considerable operator skill and experience in order to minimize variations in the outer diameter and residual bending of the shaft.

To maintain precision and finish of the outer diameter, automatic balancing of the grinding wheel is necessary. CBN grinding wheels are used although they are more expensive than traditional abrasive wheels; their long life and low wear rates make them economical.

After turning the external diameter to final size, shaft end features are produced. These features include bearing seats, keyways, flats, and locknut threads. The final finishing operation for the ballscrew generates the ball groove. This is the key processing step in assuring that the ballscrew possesses the required lead accuracy. If this process is not carefully controlled, there will be variation in the lead, depth of the groove, and smoothness of the groove, causing subsequent problems with accuracy, stiffness, running force and noise, and lifetime.

Removal of the outer layer of hardened material during outer diameter grinding can cause minor bending of the shaft as the net residual stresses in the material change. Prior to final cutting of the ball groove, the straightness of the shafts is checked and minor corrections made.

To maintain very high lead precision, the final groove grinding is done in a specially temperature-controlled environment of  $68 \pm 2^\circ\text{F}$  ( $20 \pm 1^\circ\text{C}$ ). Cutting oil is applied liberally to the shaft to minimize thermal effects due to cutting and deviations between the grinding machine and shaft temperature. As in the case of external diameter grinding, automatic balancing is used to minimize vibrations. To further reduce vibrations, each grinding machine is mounted on an individual base to minimize vibration coupling between various machines. The isolation properties of the machine bases are adjusted when a new machine is placed in service and undergo periodic inspection and adjustment during operation.

Since the size and lead of the groove varies from ballscrew to ballscrew, the grinding wheel must be matched to the groove shape. Thus, an inventory of several types of wheels is necessary; traditional abrasives are used since the costs of CBN wheels would quickly become prohibitive.

In general, accuracy in the groove-grinding process requires a combination of modeling and statistical analysis. As in the case of surface treatment, the collection and analysis of past production data allows continuous refinement of the manufacturing process.

### **Assembly and Inspection**

The main factor in ballscrew accuracy is the lead. To facilitate a quantitative measurement of the lead, four fundamental parameters are used. To measure the lead error, precision measurements over a long travel range are made using computer-controlled laser interferometry.

Unacceptable variations in friction, increased running noise, and a reduction in life result from poorly formed grooves. Thus, the depth and cross-sectional profile of the groove must fall within allowable tolerances. Direct measurement of groove cross section is quickly performed on an optical profile projector. Precise measurement of groove depth can be made on selected samples. The screw shaft is supported between two centers and rotated at a fixed speed. A table carrying a contact probe moves along the screw shaft in the axial direction synchronously with the screw rotation. The probe is placed in contact with the groove to measure variations in the groove depth over the entire length of the shaft. By performing a frequency analysis on the groove depth errors and accounting for the rotational speed of the ballscrew during the measurement process, frequencies of unwanted vibrations occurring in the production machinery can be detected and the source of the anomaly eliminated to improve the production process.

Even with good control of the screw shaft and nut groove diameters during production, additional steps are necessary to obtain the desired amount of axial play or preload in the assembled ballscrew. By selecting slightly different ball sizes, required axial play or preload can be achieved. For a given nominal ball diameter, balls usually are grouped in steps of 20 to 40  $\mu\text{in.}$  (0.5 or 1.0  $\mu\text{m}$ ). To increase production efficiency, assembly jigs are used.

The majority of precision ballscrews are preloaded in order to remove backlash and achieve the desired axial stiffness. Two methods of achieving the desired preload are used. The first preloading method increases the ball size until the desired preload is achieved. The second method uses double-nut preloading in which a spacer is inserted between the two nuts to take up the axial play and achieve the desired preload.

The preloaded ballscrew has some running torque when the screw is rotated. The relation between this running torque and the preload has been determined based on both theoretical and experimental studies. Since preload cannot be measured directly, it is estimated based on measurements of the running torque in a specialized torque-measuring machine.

A special machine is used for direct measurement of axial stiffness. In this process, the screw shaft is clamped and an axial load is applied to the nut. A displacement sensor is fixed to the shaft close to the nut and the relative displacement of the nut can be measured when force is applied. The measurements of force and displacement can be plotted on an X-Y recorder to depict the stiffness characteristics of the ballscrew assembly.

## 13.3 Essential Elements in Manufacturing Processes and Equipment

---

### Sensors for Manufacturing

*John Fildes*

#### Introduction

A good modern definition for a sensor must capture the diversity of these devices. A sensor is a device that detects or measures the state or value of a physical or chemical variable and provides the result in a useful way. At the minimum, a sensor contains a transducer that converts the detected or measured quantity to another form of representation. For example, a very simple sensor is an indicator whose color changes upon reaction with a minimum amount of a chemical species. Nonetheless, the sensors that are normally encountered are more complex, containing a transducer, an output display, and possibly supporting electronics for signal conditioning, communications, and logic functions.

Sensor technology is undergoing rapid change because of three developments. One development is the emergence of integrated and smart sensors, wherein transducers have been miniaturized, usually through the use of silicon micromachining, and integrated with electronics for signal conditioning, communications, and logic functions. The second development is the ongoing adaptation of nondestructive evaluation (NDE) measurements and laboratory measurements for on-line use in supervisory and intelligent process control systems. These NDE and laboratory-type measurements require rather complex systems, with extensive signal conditioning and data analysis. The third development is also related to the emergence of supervisory control systems. The data from multiple sensors is comparatively analyzed in a process called data fusion to better identify the state of the system and the occurrence of process faults. Thus, the topic of sensors and sensory systems now encompasses transducers, integration with supporting electronics for communications and logic functions, data analysis techniques, and data fusion methods.

#### Classification of Sensors

A good taxonomy for sensors is provided by the requirements for different degrees of process control, which is shown in [Figure 13.3.1](#). This taxonomy contains three classes: sensors used in regulatory feedback control loops, process analyzers, and product quality analyzers. In [Figure 13.3.2](#), the basic element of control is the regulatory feedback loop that maintains controllable processing parameters at the desired values. These types of sensors, which usually provide a single value and are relatively generic in their applicability, are used for monitoring variables such as temperature, pressure, flow, level, displacement, proximity, and velocity. For use of sensors in regulatory control, sensitivity, selectivity, simplicity, speed, reliability, and low cost are the critical attributes. Historically, sensors were almost solely used in this function, but this is no longer the case. Sensors, or more properly sensory systems, are now also used as process analyzers and product quality monitors. Sensors of this type, which are used for feedback in supervisory control, are more complex and application specific, and their output tends to be a matrix of values (e.g., a video image or a spectrum). Sensors of this type provide a representation of the process or product that has greater information content, but is more abstract than the representation provided by sensors used in regulatory control. Thus, extensive computations and modeling are needed for process analyzers and product quality sensors, but there is also more ability to correct for deficiencies in sensitivity and selectivity through computational means. In this case, measurement speed is usually less demanding. These differences in the three types of sensors are summarized in [Table 13.3.1](#).

The typical regulatory variables are temperature, pressure, flow, level, humidity, position, and motion. These variables form the basis for many process factors as summarized in [Table 13.3.2](#) and the major sensor technologies for these variables are summarized in [Table 13.3.3](#).

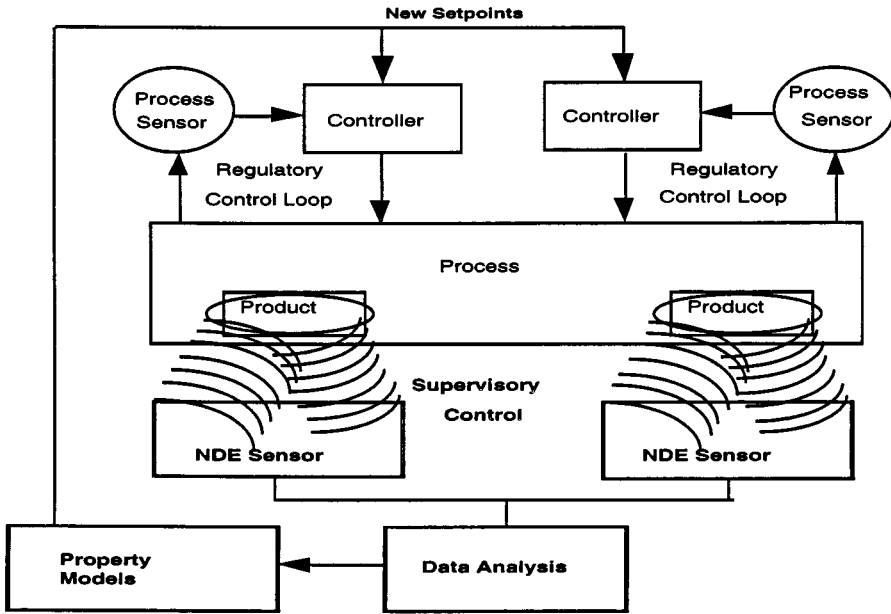

FIGURE 13.3.1 Regulatory and intelligent control.

FIGURE 13.3.2 Typical CNC architecture.

Integration refers to inclusion of signal conditioning on the same substrate as the transducer. One of the major advantages of integration is that the integrated sensor can operate with a very small transducer output, which results in significantly smaller sensors. With the advent in telecommunications and the Microelectricalmechanical systems (MEMS) technologies, we can integrate software, hardware, power

**TABLE 13.3.1 Characteristics of Regulatory and Intelligent Process Control Sensors**

Characteristic	Regulatory Feedback Sensors	Process and Product Sensors
Speed of response	Very fast	Slow
Type of output	Single value	Matrix of values
Relationship of output to system parameter	Simple and direct	Abstract representation
Amount of computation	Little or none	Extensive
Sensitivity	Inherently high	Can be improved by computation and modeling
Selectivity	Inherently high	Can be improved by computation and modeling
Cost	Very low to moderate	High
Size	Small	Large
Applicability	Broad	Application specific

**TABLE 13.3.2 Regulatory Processing Variables**

Controllable Variable	Influenced Processing Factors
Temperature	Rates of chemical reactions; degree of cure of polymers; degree of softening and viscosity; cooking times; drying times; annealing times; degree of carburization
Pressure	Consolidation density; porosity; concentration of gaseous chemical reactants; forging; bending; injection times in molding
Flow	Mix ratios; quenching time; concentration of chemical reactants; color; pH; humidity
Level	Capacity; mix ratio; concentration of chemical reagents
Humidity	Drying of paper and grains; cooking
Position	Parts handling and placement; machining accuracy
Motion	Assembly; machining accuracy

**TABLE 13.3.3 Sensor Technologies for Regulatory Control**

Variable	Major Sensor Technologies
Temperature	Thermocouples, thermistors, resistance thermometers, infrared pyrometers, acoustic pyrometers
Pressure	Manometers, bellows and diaphragms, strain gauges, piezoresistive, piezoelectric, capacitive, thermocouple, ionization
Flow	Differential pressure (orifice plate, Venturi, pitot tube); velocity (turbine, vortex, electromagnetic, Doppler ultrasonic, time-of-flight ultrasonic); positive displacement (rotary sliding vane, gear, impeller); mass flow (thermal, coriolis); variable area (rotameters)
Level	Floats, pressure, radio frequency, ultrasonic, microwave, resistance tape, optical
Humidity	Dew point, length of hair, conductivity, capacitive, resonate
Position	Rotary encoder, linear variable differential transformer, potentiometers, magnetostrictive, magnetic, inductive proximity, magnetic, ultrasonic
Motion	Tachometers, pitot tube, anemometers

source, and communications on the same chip. [Table 13.3.4](#) lists the advantages and disadvantages of integrated sensors.

**TABLE 13.3.4 Characteristics of Integrated Microsensors**

Characteristic	Advantage/Disadvantage
Batch fabrication	Excellent control, low cost, sensor arrays
Loss of modularity	Difficult to package and limitations on materials
On-chip amplification	Better signal-to-noise ratio
On-chip compensation	Better accuracy through compensation for interferences
On-chip feedback	Better linearity
On-chip scaling and conversion	Standardized output
On-chip multiplexing	Sensor arrays, bus addressable

Smart sensors are defined as those that also include logic functions, rather than just signal-conditioning electronics. Smart sensors may also include communications circuitry, diagnostics, and sometimes control outputs so that they can be directly connected to actuators, and documentation and trending functions. Conventional pressure sensors have rather broad accuracy limits, such as 0.25% of span. High-end smart pressure sensors have an accuracy of less than 0.1% of span, and mid-range smart pressure sensors approach this accuracy. Smart pressure transmitters are already available with built-in proportional-integral-derivative control functions, and fuzzy logic capabilities will soon be available. Multi-variate measurement is not yet available, but will become so soon. Most likely, pressure and temperature will be the two measurements. Smart sensors are also available for presence detection, positioning, infrared photodetection with triangulation, and flowmeters, specifically magnetic meters, Coriolis mass flowmeters, and ultrasonic flowmeters. Integrated and smart sensor technology is also improving accelerometers, proximity detectors, and tactile sensors. The use of integrated and smart sensors will increase because of the overloading of shared resources and the use of distributed control schemes to solve this problem.

### Use of Sensors in Supervisory and Intelligent Control Systems

As shown in [Figure 13.3.1](#), supervisory control augments regulatory control by using process analyzers to better characterize the state of the process and sensors of product characteristics to assess the outcome of the process and to determine corrections for unacceptable deviations. These corrections are then implemented by the regulatory controllers. There are many ways in which supervisory control can be implemented. A common way is to measure important aspects of the process and the product performance, and to use a model to relate variations in processing parameters to variations in product performance.

Process analyzers are central to enabling supervisory control because they allow a more accurate, but abstract, representation of the state of the process. These devices augment regulatory control by monitoring other important variables in the process, but ones which are generally not directly controllable. Use of process analyzers provides improved reliability, flexibility, predictive diagnostics, ease of use, and central data collection with process documentation, trending, recipe handling, and statistical quality assurance. Process analyzers are now used for monitoring important process gases such as oxygen, carbon monoxide and dioxide, oxides of nitrogen and sulfur, and hydrocarbons. For liquids, process analyzers are available for pH, conductivity, redox potential, dissolved oxygen, ozone, turbidity, specific ions, and many organic compounds. The measurement techniques are summarized in [Table 13.3.5](#).

**TABLE 13.3.5 Process Analyzers**

Process Analyzer Technology	Typical Uses
Electrochemical (potentiometric, amperometric)	Gases such as carbon monoxide and dioxide, oxides of nitrogen and sulfur, and hydrocarbons; species in liquids such as dissolved oxygen, pH, redox potential, specific ions, organic compounds, inorganic compounds
Chromatography (gas and liquid)	Gases such as CO and CO <sub>2</sub> ; species in liquids such as alcohols, flavors, lipids, polymers, and other organic compounds
Infrared spectroscopy	Near infrared — web processes for thickness, composition, solvent, coating Mid-infrared — chemical and petrochemical processes, polymers, food processes
Ultraviolet/visible	Gases and liquids including all elemental halogens, other inorganics, aromatics, carbonyls, many salts of transition metals

Traditionally, process analyzers have been stand-alone devices with a single sensor and a dedicated operator interface. The trend is toward modularity, multiple sensors, and digital communications so that process analyzers can be incorporated into distributed control systems in an open architecture control environment. Smart sensor technology is also turning conventional sensors into process analyzers. A good example is provided by smart infrared temperature sensors. These sensors provide sample and hold, correction for reflected radiation when the emissivity of the target is less than one and its temperature

is lower than ambient, analog outputs for control, digital outputs, trend analysis, and area sampling with line scanners. This functionality has made temperature mapping of surfaces in furnaces practical and is used in annealing of aluminum, steel reheating, and oven drying of webs such as paper.

Another trend is the use of sensor fusion, where information from multiple sensors is combined to improve the representation of the process. Sensor fusion techniques can use mechanistic models, statistical models, or artificial intelligence techniques, such as neural networks, fuzzy logic, and expert systems. Sensor fusion provides more reliability because the validity of the data of each sensor can be assessed from the other sensors, and if a sensor is faulty, its value can be predicted from the other sensors. Sensor fusion provides a better representation of the process because it captures the interrelationships that often exist between processing variables, which are treated independently without sensor fusion.

As shown in [Figure 13.3.1](#), intelligent control involves the use of product quality sensors. Of the three classes of sensors discussed in this section, these sensors tend to be the most complex and provide the most complete, but abstract, representation of the state of the product. In some cases, the same technologies are used for product quality sensors as for process analyzers. An obvious example would be where chemicals are reacted without a change of state. In other cases, specialized product quality sensors have emerged. [Table 13.3.6](#) lists some of the product quality sensors that are being used or are being experimentally evaluated.

**TABLE 13.3.6 Product Quality Sensors**

Sensor	Applications
Time-of-flight ultrasound	Either thickness or elastic constants, if the other is known
Electromagnetic acoustic transducer (EMAT)	Either temperature or elastic constants, if the other is known
Eddy currents	Electrical conductivity, magnetic permeability, thickness, temperature, presence of flaws
NMR (high resolution for liquids, low resolution for solids)	Composition of chemicals, petroleum, foods, polymers, fibers
Infrared and Raman spectroscopy	Degree of cure of polymers

## Computer Control and Motion Control in Manufacturing

*Yoram Koren and M. Tomizuka*

### Computerized Numerical Control Architecture

A typical architecture of a CNC system consists of three levels, as shown in [Figure 13.3.2](#). At the lowest level are the axial servocontrol loops and the spindle controller. These servoloops are closed at high sampling rate. The interpolator that supplies the axial position commands to the control loops is at the intermediate level of this architecture. At the highest level are the compensation algorithms for the errors of mechanical hardware deficiencies, such as machine geometry errors and thermal deformation of the machine structure. This level also includes adaptive control algorithms that adapt the machine feed and speed to the cutting tool and workpiece material to maximize machine productivity at rough cutting and maintain precision at fine cutting.

### CNC Part Programs

The CNC software consists of a control program and part programs. The numerical data which are required for producing a specific part by a CNC machine is called the *part program*. The part program is arranged in the form of *blocks* of information, where each block contains the numerical data required to produce one segment of the workpiece. Each block contains, in coded form, all the information needed for processing a segment of the workpiece: the segment shape and length, its cutting speed, feed, etc. Dimensional information (length, width, and radii of circles) and the contour shape (linear, circular, or other) are taken from an engineering drawing. In NC, dimensions are given separately for each axis of

motion ( $X$ ,  $Y$ , etc.). Cutting conditions such as cutting speed, feed rate, and auxiliary functions (coolant on and off, spindle direction, clamp, gear changes, etc.) are programmed according to surface finish and tolerance requirements.

The part program contains the required positions of each axis, its direction of motion and velocity, and auxiliary control signals to relays. The controller generates an internal signal indicating that the previous segment is completed and that the new block of the part program should be read. The controller also operates the drives attached to the machine leadscrews and receives feedback signals on the actual position and velocity of each one of the axes.

In CNC systems the part dimensions are expressed in the part programs by integers. Each unit corresponds to the position resolution of the axes of motion and is referred to as the *basic length-unit* (BLU). The BLU is also known as the “increment size” or “bit-weight,” and in practice it corresponds approximately to the accuracy of the system. To calculate the position command that the computer sends to the CNC machine, the actual length is divided by the BLU value. For example, in order to move 0.7 in. in the positive  $X$  direction in a system with  $BLU = 0.001$  in., the position command is  $X + 700$ .

In the first generations of CNC systems, dimensions were given in part programs by BLUs, as in NC. In new CNCs, however, dimensions, or desired cutter positions, are given in a normal way, as to a regular computer. The command  $X - 0.705$ , for example, will move the  $X$  axis the negative direction by 0.705 in. The resolution by which the dimension commands are given depends on the system BLU.

In addition to cutter positions, the part programmer must program the machining parameters such as tool diameter, cutting speed ( $n$ ), feed ( $s$ ), and depth of cut ( $d$ ). The task of the part programmer is to convert the machining parameters  $n$  and  $s$  to NC control variables — spindle speed ( $N$ ) and feed rate ( $f$ ), as shown in Figure 13.3.3.

FIGURE 13.3.3 Conversion of machining parameters to control variables.

### Point-to-Point and Contouring Axes of Motion

CNC systems consist of two functional types: point to point (e.g., drilling machine) and contouring or continuous path (e.g., milling machine).

*Point-to-Point Systems.* The simplest example of a point-to-point (PTP) CNC machine tool is a drilling machine. In a drilling machine the workpiece is moved along the axes of motion until the center of the hole to be drilled is exactly beneath the drill. Then the drill is automatically moved toward the workpiece (with a spindle speed and feed which can be controlled or fixed), the hole is drilled, and the drill moves out in a rapid traverse feed. The workpiece moves to a new point, and the above sequence of actions is repeated.

In a PTP system, this system requires only position counters for controlling the final position of the tool upon reaching the point to be drilled. The path from the starting point to the final position is not controlled. The data for each desired position is given by coordinate values. However, in high-speed drilling applications, such as the task of single-spindle drilling of an engine block, a control loop is needed to control the acceleration and deceleration of the motion. The digital signal processing technique has been used to control the settling time of the motion system for very fast PTP motion profile (1 to 4 g) so that the spindle could perform drilling operations without breaking the drill. A linear motor-based machine tool has been built and demonstrated by Anorad Corp. (Hauppauge, NY) for Ford Motor’s engine machining line.

*Contouring Systems.* In contouring, or continuous-path, systems, the tool is cutting while the axes of motion are moving, as, for example, in a milling machine. All axes of motion might move simultaneously, each at a different velocity. When a nonlinear path is required, the axial velocity changes, even within the segment. For example, cutting a circular contour requires a sine-rate velocity change in one axis, while the velocity of the other axis is changed at a cosine rate.

In contouring machines, the position of the cutting tool at the end of each segment together with the ratio between the axial velocities determines the desired contour of the part, and at the same time the resultant feed also affects the surface finish. Since, in this case, a velocity error in one axis causes a cutter path position error, the system has to contain continuous-position control loops in addition to the end point position counters. Consequently, each axis of motion is equipped with both a position loop and a position counter. Dimensional information is given in the part program separately for each axis and is fed to the appropriate position counter. Then, an *interpolator*, in the controller, determines the proper velocity commands for each axis in order to obtain the desired tool feed rate.

*Interpolators.* In contouring systems the machining path is usually constructed from a combination of linear and circular segments. It is only necessary to specify in the part program the coordinates of the initial and final points of each segment and the feed rate. The operation of producing the required shape based on this information is termed *interpolation*, and the corresponding software algorithm in CNC is the *interpolator*. The interpolator coordinates the motion along the machine axes, which are separately driven, to generate the required machining path. The two most common types of interpolators are the linear and circular. Parabolic interpolators are also available in a few CNC systems which are used in the aircraft industry.

*Linear interpolator:* The ability to control the movement along a straight line between given initial and final coordinates is termed *linear interpolation*. Linear interpolation can be performed in a plane (two dimensional), using two axes of motion, or in space (three dimensional), where the combined motion of three axes is required. In this chapter only two-dimensional linear interpolators are discussed. To illustrate the interpolator function, consider a two-axis system, where a straight cut is to be made. Assume that the  $X$  axis must move  $p$  units at the same time that the  $Y$  axis moves  $q$  units. The contour formed by the axis movement has to be cut with a feed rate of  $V$  length-units per second (e.g., mm/sec). The numerical data of  $p$ ,  $q$ , and  $V$  are contained in the part program and are fed into the interpolator. The interpolator then generates two velocity signals  $V_x$  and  $V_y$ , where

$$V_x = \frac{pV}{\sqrt{p^2 + q^2}}$$

and

$$V_y = \frac{qV}{\sqrt{p^2 + q^2}}$$

The position reference inputs to the axial control loops are

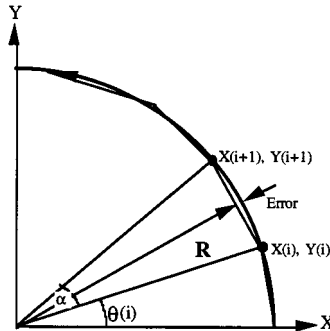

$$R_x = V_x t$$

and

$$R_y = V_y t$$

As seen, the two-dimensional linear interpolator supplies velocity commands simultaneously to the two machine axes and maintains the ratio between the required incremental distances.

*Circular interpolator:* The two most common interpolators in CNC systems are linear and circular. The *circular interpolator* eliminates the need to define many points along a circular arc. Only the initial and final points and the radius are required to generate the arc. The circular interpolator divides the arc into straight lines with a contour error smaller than one BLU. It operates on an iterative basis, where

**FIGURE 13.3.4** A circular interpolator divides the arc to straight lines.

for a given point,  $x(i), Y(i)$ , a small incremental angle is added to calculate the next point, as shown in [Figure 13.3.4](#).

Both the linear and circular interpolators are based on generating incremental positions every  $T$  seconds, where  $T$  is the sampling period of the CNC system. Typically, CNC systems operate on one common sampling period for both the interpolator and the control loops. In these systems a typical  $T$  may be between 1 and 10 msec. Some other CNC systems utilize a separate computer for the interpolation and another one or several microprocessors for closing the control loops.

### Motion Control Systems

*Control Loops.* A typical closed loop of a CNC machine is shown in [Figure 13.3.5](#). The computer compares the command and the feedback signals and gives, by means of a digital-to-analog converter, a signal representing the position error of the system, which is used to drive the DC servomotor. The feedback device, which is an incremental encoder in [Figure 13.3.4](#), is mounted on the leadscrew and supplies a pulsating output. The incremental encoder consists of a rotating disk divided into segments, which are alternately opaque and transparent. A photocell and a lamp are placed on both sides of the disk. When the disk rotates, each change in light intensity falling on the photocell provides an output pulse. The rate of pulses per minute provided by the encoder is proportional to the revolutions per minute of the leadscrew.

**FIGURE 13.3.5** Closed loop of CNC.

Normally, the motor is mechanically coupled to the load via a drive mechanism. For example, robot links and positioning tables are loads. It is usually a good assumption to ignore the dynamics in the current feedback loop and regard the command current as the actual current, which sets the torque input to the mechanical portion of the system. Notice that the inertia and bearing friction of the motor must be considered as a part of the mechanical portion of the motion control system, which strongly influences the design of the velocity and position loop feedback controllers. These controllers can be implemented

in either analog or digital form. In recent years, digital implementation on microprocessors and/or DSPs has become popular, and digital velocity and position controls are often referred to as *digital servo*. The current feedback is usually built into the “drive” (power amplification system). While feedback signals for the velocity and position controllers are usually obtained from the motor, the velocity and position of the load, e.g., a positioning table, at the opposite end of the drive mechanism are the quantities of our ultimate concern. Closed-loop control schemes based on the motor velocity and position are sometimes called semi-closed-loop control schemes. The velocity and position of the load must be fed back for full closed-loop control. Typical drive mechanisms are ballscrews and various types of gears. Several manufacturers provide so-called direct drive (DD) motors, which are capable of delivering large torques but with a significantly reduced maximum speed. DD motors may eliminate drive mechanisms. However, they are heavy and may not always be the best solution depending on applications. Common sensors for positions are potentiometers and shaft encoders, and those for velocities are tachogenerators and frequency-to-voltage convertors (FVC), the input to which is encoder pulses. In digital servos, encoders are popular for measuring positions, and velocities are either estimated from encoder pulses or are obtained from FVCs.

Traditional velocity and position loop feedback controllers are of PID (proportional plus integral plus derivative) type. The output of a PID controller is

$$u(t) = k_p e(t) + k_i \int_0^t e(\tau) d\tau + k_d \frac{de(t)}{dt}$$

where  $e(t)$  is the error,  $u(t)$  is the controlling input, and  $k_p$ ,  $k_i$ , and  $k_d$  are, respectively, proportional, integral, and derivative control gains. The above equation represents the PID control law in the continuous-time (analog) form. In digital control, the PID control law is implemented in a discretized form. A typical discrete-time (digital) PID control law is

$$u(k) = k_p e(k) + k_i T \sum_{j=0}^k e(j) + \left( \frac{k_d}{T} \right) [e(k) - e(k-1)]$$

where  $k$  denotes the  $k$ th sampling instance and  $T$  is the sampling period. In position loop feedback control,  $e$  and  $u$  correspond to the positioning error and the velocity command, respectively. For the velocity loop controller, they are the velocity error and the current command. Another popular linear controller is the lead/lag compensator. Input-output (I/O) interfaces include analog-to-digital convertors (A/D), decoders for processing encoder pulses, and digital-to-analog convertors (D/A). Motion control systems can be built from components and programmed with custom software, they can be purchased as plug-in boards for various buses, or they can be purchased as packaged systems.

PID and lead/lag compensators are simple and utilized in many applications. However, they alone might not be adequate for problems where the performance requirements are stringent. Extreme care must be taken during the design of a closed-loop control system. By increasing the magnitude of the feedback signal (e.g., more pulses per one revolution of the leadscrew), the loop is made more sensitive. That is known as increasing the open-loop gain. Increasing the open-loop gain excessively may cause the closed-loop system to become unstable, which obviously should be avoided.

The basic nature of “feedback” control is that the control action is based on the error. When the reference input for the position loop is fixed, the integral action may assure zero error at the steady state. In tracking control, however, the position command is continuously varying, which combined with the dynamics of the closed-loop system makes tracking errors always remain. For example, in contouring of a circular arc in machining, the command position signal for each motion control axis is sinusoidal. Such an operation is essentially a test of the frequency response of the motion control axis. The controller is normally tuned so that the frequency response gain is close to but is not exactly 1 in the operating range. In high-speed contouring operations, corresponding frequencies are high, and the gain is normally

below unity. Then, the actual diameter is slightly smaller than the desired diameter. This consequence is often called the radial reduction error. Such errors may be reduced by applying the disturbance observer scheme to the position loop. However, the disturbance observer is still a feedback controller, and one sampling time delay in digital implementation further diminishes its effectiveness.

The following discussion describes some principles of motion control systems for PTP machines and contouring machines.

**Control Loops for Point-to-Point Systems.** The control loops of PTP systems are designed to control the position of the machine tool axes. Each axis is *separately* driven and should follow the command signal. The system design starts by selecting the type of control: open loop or closed loop, a decision which depends on the required specifications of the NC system and economy. Open-loop controls use stepping motors as the drive devices of the machine table. The drive units of the stepping motors are directly fed by the controller output pulses. The selection of the appropriate motor depends on the maximum torque, required velocity, and step size in the system. Stepping motors can be implemented on small-sized PTP systems in which the load torque is small and constant. Larger PTP machines and contouring systems utilize closed-loop control systems.

In PTP systems each axis is driven separately at the maximum allowable velocity. This velocity depends on the drive type and on the mechanical structure of the particular machined or manufacturing system. In order to avoid large overshoots the velocity is decelerated before the target point in which the tool starts to operate (e.g., to drill). Since the path between the points is insignificant, *the deceleration is accomplished in each axis separately.*

In practical systems the deceleration is accomplished by three stages. A typical three-stage deceleration diagram of one axis of the table is given in Figure 13.3.6. The table moves at rapid velocity  $V$  until reaching a distance  $L_1$  from the target point, where the table is instructed to move at smaller velocity  $V_1$ . After a time delay, which depends on the system inertia, the table moves at a new velocity  $V_1$  until reaching a distance of  $L_2$  units from the target point, where again the velocity is reduced to  $V_2$ . When the table is at a distance of  $L_3$  units before the target point, the velocity is reduced once more and the table “creeps” toward the final point at very low velocity  $V_3$ , and subsequently stops.

**FIGURE 13.3.6** Deceleration procedure in a PTP system.

**Control Loops for Contouring Systems.** The control in CNC contouring systems operates in closed loops, which compare the command pulses from the interpolator with the feedback signal from the encoder or the resolver. The most sophisticated design applies to the closed-loop control of contouring systems. In the design of these loops, the transfer function of each element must first be determined; the system is then set up in block diagram form, and finally the loop gain is established based on performance analysis. The transfer function of each element is based upon its mathematical model. In establishing the mathematical model the engineer is faced with a compromise between *accuracy* and *complexity*, on one hand, and *approximation* and *simplicity*, on the other. In this section we shall discuss simple models, in which the principles of design can be readily illustrated.

The control loops of contouring systems are usually of the closed-loop type as shown in Figure 13.3.7. They use two feedback devices: a tachometer that measures the motor speed and is included in the drive unit and a position feedback transducer which is capable of also measuring the axis velocity (such as

an encoder, resolver, or inductosyn). In encoder-based systems the encoder is mounted on the leadscrew and emits pulses; each pulse indicates a motion of 1 BLU of axis travel. Therefore, the number of pulses represents position and the encoder pulse frequency is proportional to the axis velocity.

FIGURE 13.3.7 Control loop of contouring system.

### Error Sources in CNC Systems

Despite the high precision of the CNC equipment, it still has position and contour errors. Error sources in CNC machines are classified into three categories:

1. Mechanical Hardware Deficiencies
  - Orthogonality of machine axes
  - Straightness of the machine axes
  - Thermal deformation of the machine structure
  - Backlash in the gears and leadscrew nuts
  - Uneven leadscrew pitch
  - Friction in moving components (leadscrews, guideways, etc.)
2. Cutting Process Effects
  - Tool deflection due to cutting forces
  - Large vibrations and chatter
  - Tool wear
  - Workpiece thermal deformations
  - Workpiece deformations due to cutting forces
3. Controller and Drive Dynamics
  - Disturbances due to cutting forces
  - Disturbance due to friction forces in the machine guideways
  - Contour errors caused by tracking errors of nonlinear contours (e.g., circles)
  - Contour errors caused by mismatch of equivalent parameters in the axial controllers
  - Corner errors in contouring operations

In general, errors of the first type, such as machine geometry errors and thermal deformation of the machine structure, can be compensated for by the machine controller. To further understand the measurement of errors, the next section will examine the metrology for precision engineering.

### Introduction

Precision engineering in manufacturing generally refers to the engineering processes of achieving tighter tolerances or dimensional accuracy of a design. The process of precision engineering begins from the part *design*, part *fabrication*, and, finally, part *inspection*. This section addresses some of today's precision engineering considerations in fabrication and inspection.

### Factors in Precision Engineering

The fabrication process is a material transformation process that determines the final part dimensions through material forming, removal, or insertion. Precision in the fabrication generally refers to the dimensional "repeatability and accuracy" of a part transformed under such a process. The factors to be considered to ensure good "precision" are (1) errors of the *machine* system(s), (2) the *environment* in which the machining is being performed, (3) the *manufacturing process*, and (4) the *instrumentation* to verify the performances of the factors.

**Machine Errors.** Machine errors can be classified into geometric, thermal-induced, dynamic, and structural errors. Geometric errors are errors related to the undesirable machine geometry caused by nonorthogonality (squareness error) of axes, linear positioning (or scale) error, reversal (or backlash) error, straightness error, pitch, yaw, and roll errors of a machine axis during a linear move. If the machine is equipped with a rotary table, geometric error would include axis wobble, rotational positioning error, eccentricity, and parallelism errors.

*Geometric Errors:* Geometric errors are much better understood in the machine industry than the thermal, dynamic, and structural errors. The techniques and instruments to check for the geometric error are very well established and are commonly applied in the machine tool industry. However, for small- to medium-size machines, geometric errors constitute only about 25% or less of the total manufacturing error. For larger machines, the percentage can go as high as 50%. As such, just knowing the geometric errors of a machine system may not be adequate in the realization of the total manufacturing error.

Traditional devices for measuring different types of geometric errors are the mechanical square, straightedge, autocollimator, electronic level, step gauge, optical polygon, and dial indicator. In some instances, the combined use of these devices is needed. Newer instruments that can offer faster and more precise measurements are the laser interferometer system, the 5-D laser interferometer system, and the telescopic ballbar.

*Thermal Errors:* Thermally induced machine error is considered one of the key factors affecting the accuracy of a machine tool. Thermally induced errors arise as a result of nonuniform heat generation within the machine such as in motors, bearings, and guideways; heat generated during the cutting process; and the coolant effect as well as the environmental effect resulting in the uneven growth of the machine structure. Thermal error can contribute as much as 50% of the total manufacturing error in small- to medium-size machines. However, this effect has been largely unrecognized or often ignored by the machine tool industry until recently.

There are basically two alternatives to monitor the thermally induced errors — intermittent and continuous monitorings. Intermittent monitoring generally involves the use of a touch probe or dial indicator(s) to periodically measure against one or multiple fixed positions as the machine is going through a thermal exercise. In the case of the dynamic spindle thermal study, an artifact such as a sphere or a rod can be mounted on the spindle while it is running at a certain speed. At some elapsed time (e.g., 1-min interval), the spindle will stop momentarily and the machine will reposition the artifact to the dial indicator(s) to check for the repeatability. Any deviations from the initial position (i.e., cold-start position) are considered as thermal growth due to the spindle warm-up. A typical spindle thermal test takes about 4 to 8 hr to complete. A similar procedure can be applied for the environmental and servomotion-related thermal growth measurements.

The continuous thermal growth monitoring generally involves the use of some noncontact sensors such as capacitance gauges, optical sensors, or inductance sensors arranged in the similar fashion as above. The benefits of continuous monitoring are that there is no interruption of the spindle dynamic and that the machine positioning repeatability does not necessarily interfere with the results. Furthermore, the noncontact nature generally allows the spindle to operate at any speeds, thus giving a much broader range of thermal assessment.

Laser interferometer systems are also used occasionally to monitor thermal growth effects. Because of its ability to identify the growth along the entire axis, the laser measurement is better suited for monitoring the growth of a linear-scale system caused by internal or external heat sources. Linear-scale error caused by axis movement is about one fifth that of the spindle thermal in medium to small machines. It is even less in larger machine since the heat dissipation effect in larger machine is much more effective.

*Dynamic Errors:* Dynamic errors here refer to those caused by the motions of a CNC machining center. These includes the servo-gain mismatch, servo-stick-slip, servo-oscillation, controller error, etc. Errors pertaining to tool chattering, structural deformation (caused by machine carriage acceleration and deceleration), machine/part deadweight, etc. are considered structural errors and are discussed in the later section.

Servo-gain mismatch is often caused by the electrical (or computer) gain setting of one axis not matching the other. The problem is not severe when the machine is primarily used for static positioning purposes, such as drill, boring, etc.; however, it can be a problem in precision contour milling when two or more axes are to be used in synchronization with each other. The magnified elliptical error is caused by one axis responding faster than the other in reaching the commanded positions. Servo-gain mismatch can easily be corrected in a routine machine maintenance.

*Structural Errors:* Structural errors include tool-chattering error and structural deformation error (due to acceleration and deceleration of the machine carriage, the deadweight distribution, the cutting force, etc.).

Tool chattering generally affects the machinability and surface finish of the workpiece, not the dimensional accuracy. Structural deformation caused by the acceleration and deceleration of the machine carriage and workpiece is rather insignificant for quasi-static positioning and slow-speed contouring. However, the error can be significant if the contouring speed is high. Another major contributor to the structural error is the cutting force. An excessive amount of cutting force can cause the spindle axis, the tool, the fixture, and the part to deform.

A good device to gauge the potential structural error is a compliance system. A basic compliance system consists of a load cell and a dial indicator, which are set up between the machine table and the spindle. The table is programmed to move in small increments (e.g., 5 mm) in either directions of the load cell. The readings from the load cell (force) and the indicator (actual displacement of the table) are then recorded at every increment. A compliance chart can then be obtained by plotting the forces ( $F$ ) against the differences between the actual and commanded displacements ( $DD$ ) of the table (i.e.,  $F$  vs.  $DD$ ).

Another type of structural error for large machines is from the machine foundation error. Most large machine bases are built in sections. These sections are then aligned, assembled, and anchored together to a common reinforced concrete foundation. As such, the foundation becomes part of the machine structure and the accuracy and repeatability of the machine are therefore heavily dependent on the stability of the foundation. It is not unusual to find the performance of the machine degraded as a result of floods and earthquakes, and loosening of anchor supports due to prolong use or lack of maintenance.

***Errors Introduced by Environmental Effects.*** For the manufacturing plants that have little or no control of the plant environment, environmental effects can be very significant sources of errors. Two of the most dominant environmental effects are thermal and vibration effects.

*Thermal Errors:* For many nontemperature-controlled manufacturing plants, it is not unusual to observe a total temperature swing of 20°F throughout a day of operation. This wide fluctuation of environmental temperature can cause significant accuracy and repeatability problems to the machining

systems, as well as the workpieces. Even in a somewhat controlled environment, thermal errors can still be a major problem. For instance, if the machine is located in the vicinity of a frequently operated bay door, where there is a substantial temperature difference between the plant temperature and the outdoor temperature, or if it is placed next to a heat source such as a welder, an electric blower or exhaust, a hydraulic pump, or under direct sunlight, the heat source can still cause tremendous localized thermal distortion of the machining system.

In most cases, one can reduce the localized environmental thermal effect by isolating the heat sources with simple panel shielding or by relocating the machines. If an overall plant temperature control is unachievable or impractical for economic reasons, one may consider (1) applying localized thermal control of certain key machining systems or (2) implementing computer thermal compensation techniques.

*Vibration Errors:* Environmental vibration error is a result of one or more external vibration sources affecting the structural stability of the machine system. This type of error can be significant if the machining system is located next to a heavy punch press operation or where frequent forklifting operation is present. Using a spindle analyzer or a laser interferometer system to access the amount of the environmental vibration error is common.

*Other Errors:* Other types of environmental errors are the interference or instability of the electric power source, the factory-supplied pneumatic and hydraulic pressures, air pressure, and humidity, etc. These types of errors may be of lesser magnitude than the above; however, it is always good practice not to underestimate their potential effects in any precision manufacturing considerations.

### ***Errors Introduced by the Manufacturing Process .***

The magnitudes of these types of errors are very much dependent on the process control and manufacturing practices implemented by each individual plant. In general, the concerns in this area are the effects of the coolant on the workpiece and the machine structure, the pallet and the fixture, the repeatability of the pallet and tool changer, and the tool deflection in manufacturing.

*Coolant Effects:* Eighty percent of machining uses coolant, sometimes referred to as *wet machining*. In most cases, the coolant temperature is not controlled. For smaller machining systems, a small coolant tank can be found next to the machine. For larger machines, a large coolant tank can be found underneath the ground. The main purposes of the coolant in machining are (1) for lowering the cutting temperature and (2) for chip removal. As the coolant is being recycled during the machining process, its temperature gradually warms up. This significant increase in temperature affects the workpiece dimensions since the workpiece temperature before machining is generally at room temperature. Similarly, the pallet dimensions are also affected.

*Tool and Fixture:* The conditions of the pallets, tools, and fixtures often govern the repeatability of a manufacturing system. These components should be checked routinely for wear and chipping. Fixtures and clamping devices should be routinely checked to ensure that proper clamping forces can be applied and that contact surfaces are in good condition. Many of these checks can be accomplished visually or by performing dial indicator repeatability checks.

When excessive cutting force is expected, it is necessary to consider the maximum possible amount of the tool, workpiece, and fixture deflections resulting from the force. The amount, if it exceeds the manufacturing tolerance, should be reduced by either reducing the depth of cut or the feed rate or by strengthening the tool and fixture. A compliance system is a good qualifier to measure the tool deflection under load.

## **Instrumentation and Inspection in Precision Engineering**

This section introduces the instrumentation often used in precision engineering.

### CNC Machining Performance Evaluation

The American National Standards Institute developed *ANSI B5.54 Standards for CNC Machining Center Performance Evaluation* for the purpose of providing detailed guidelines for machine tool users and developers to evaluate and compare the performances of CNC machining systems. The *Standards* delineates procedures for the measurements of the machine and environmental errors as stated in the above, as well as choices of conventional and state-of-the-art instruments used in doing the measurements. Experience indicates that these measurements are useful not only for performance evaluation, but also for better understanding of the sources of errors. This information is crucial for preventive maintenance and for accuracy enhancement of CNC machine systems.

Some of the key techniques introduced by the *B5.54 Standards* are the telescopic ballbar measurement, spindle dynamic and thermal drift measurement, laser diagonal measurement, and the 1-day test.

### Instrumentation and Metrology

**Telescopic Ballbar.** The telescopic ballbar test is gradually becoming one of the most powerful and convenient tests for CNC machining center evaluations. As is shown in Figure 13.3.8, a telescopic ballbar consists of a spring-suspended reed having two spheres attached to both ends. The spheres are allowed to move relative to each other with a limited travel, e.g., 3 to 4 mm. Inside the reed is a displacement sensor, known as an LVDT (linearly variable displacement transducer), that measures the relative move of the spheres. The output of the LVDT is connected to a computer.

**FIGURE 13.3.8** The telescopic ballbar.

To use the telescopic ballbar, one of spheres is magnetically attached to the magnetic socket which is installed on the machine spindle; the other is magnetically attached to a second magnetic socket mounted on the table. The machine is then programmed to contour in a circle in the X-Y, X-Z, or Y-Z plane, as shown in Figure 13.3.8. As the contouring proceeds, any errors of the machine in contouring will be translated into relative moves picked up by the LVDT and instantaneously recorded by the computer. After the machine has stopped, the computer then plots the errors on a chart for analysis. Errors such as backlash, axes nonsquareness, scale mismatch, servo-gain mismatch, cyclic motion, stick-slip, and certain straightness errors can be readily detected by using a telescopic ballbar.

**Laser Interferometer.** A laser interferometer system can produce measurements pertaining to the linear, angular, straightness, and squareness errors of a machine system. To many in the manufacturing industry, laser interferometer measurements are considered as the primary calibration standards. However, it is important that when using a laser interferometer, the proper procedures are followed. Precautions should

be taken when using a laser interferometer system: avoid setting up the laser in areas where large air turbulence is present; set up the laser to minimize the cosine error and Abbe error; beware of the environmental effects (i.e., temperature, pressure, and humidity) to the laser accuracy; and understand the material parameters (i.e., material temperature, coefficient of expansion, etc.) to the measuring accuracy. In the event that these effects are significant, it is necessary to compensate for them in the final results.

Setting up a laser interferometer system for machine measurement can be very tedious and sometimes frustrating. It is not unusual to take 2 to 3 days to measure all linear, straightness, angular, and squareness of a mid-size three-axis CNC machine (referred to as 21 parameters measurement). A new laser system known as the 5-D laser interferometer system, developed by Automated Precision, Inc. (Gaithersburg, MD), has the capability of measuring five degrees of freedom (i.e.,  $X$ -,  $dY$ ,  $dZ$ , pitch, and yaw) simultaneously in one single setup. In contrast, the 5-D system is able to cut down the measuring time to 3 to 4 hr.

A laser interferometer system should not be confused with an alignment laser system. A laser interferometer system works on the polarized light interference principle and can produce precision to within a tenth (or better) of a wavelength of light (i.e., 630 nm for an HeNe laser). By using the same measuring principle, a laser interferometer system can also generate angle measurements to within 0.1 arc-sec. An alignment laser works on beam-pointing effects and combines the measurements with a photodetector for straightness and angle measurements (not linear measurement). In this case, the laser beam is used as a straightedge. Unless the electro-optics elements are used carefully, the accuracy is much lower than that of a laser interferometer system. Although alignment lasers are commonly used in machine alignment, it should not be construed as a precision calibration standard.

*Spindle Analyzer:* A spindle analyzer can be used to measure several important parameters of a machining system. These include thermal growth of a machine resulting from environmental variations (i.e., temperature, vibration, etc.) and internal heat sources (i.e., motors, spindle bearings, hydraulic systems, etc.), spindle dynamic errors resulting from a worn or contaminated bearing, and machine axis repeatability.

For advanced applications, it is recommended that the sensors be of noncontact nature since contact sensors can create problem when measuring a high-speed spindle in motion. The noncontact sensors can be optical, capacitive, or inductive. They all have their advantages and disadvantages dependent on their applications. Users should consult with the manufacturers before making their selections.

*Other Metrology Instruments.* The above-mentioned metrology instruments represent some of the latest and most commonly used instruments in the manufacturing industry. Other instruments that are also used frequently are electronic autocollimators, electronic levels, force gauges, temperature sensors, vibration sensors, dial indicators, proximity sensors, mechanical straightedges, step gauges, precision-indexing tables, etc. One should not, however, overlook the benefits offered by some of the latest data acquisition and data analysis software packages such as the SPC (statistical process control). Of course, the proper selection and use of any instrument are keys to a better understanding of the factors in precision manufacturing.

### *Inspection System and Metrology*

The direct-computer-controlled coordinate measuring machine (DCC-CMM) has been the dominating means for final workpiece dimensional inspection in the manufacturing industry since the early 1980s. Since then, several advanced dimensional measuring devices have also been developed and are gaining wide acceptance in industry. These are the high-speed laser tracking systems and the manually operated measuring robots. There is also a growing interest in the manufacturing industry to reduce the off-line inspection process (i.e., CMM-type applications) by performing some of the inspections on the CNC machining system. This is referred to as on-machine gauging. This section will discuss some of the key considerations related to the use of these advanced inspection systems.

*Laser Tracking Interferometer System.* The laser tracking interferometer system (LTS) was developed at the National Institute of Standards and Technology (NIST) in the mid-1980s for medium- to large-dimensional inspections. It was then commercialized and introduced to the industry in late 1989. Since then, the LTS has been gaining popularity and is becoming one of the dimensional measuring standards.

Through the combination of a precision dual-axis gimbal, a laser interferometer system and an optical target (i.e., a retroreflector), the laser beam is precisely directed to the target through the manipulation of the gimballed mirror via the control computer. As the beam is sent back to the laser by the target, it is partially deflected to a dual-axis photodetector. The beam position is then interpreted by the computer. As the target moves, the photodetector immediately generates an error signal to the computer which drives the mirror to ensure the beam stays locked onto the target. While it is tracking, the computer acquires the laser measurement and the two angle measurements ( $a$  and  $b$  angles) of the mirror and computes for the three-dimensional position of the target.

The advantages of the LTS are that (1) it is considered one of the most accurate large-dimensional coordinate measuring devices with an accuracy of better than 10 ppm (i.e., 100 mm at 10 m); (2) it has a very measurable envelope — 25 m  $\times$  360°; (3) it can track a target moving at a speed of 4 m/sec; (4) it can sample up to 1000 samples/sec; and (5) it is compact, portable, and fully automatic. It is well suited for rapid surface scanning, jigs and fixture alignment, replacing conventional CMMs for large structural measurements, and for large CMMs, robotic devices, or CNC machining center calibrations.

The disadvantages are that (1) when used in areas where significant air turbulence is present, the system becomes less reliable; (2) the accuracy may be reduced when used in areas where heavy forklifting activities are present (since the floor foundation is part of the measuring frame); and (3) the system needs zero referencing if the interferometer beam is interrupted during measurement.

*On-Machine Gauging.* On-machine gauging (or in-process gauging) refers to the dimensional inspection process implemented during or after a machining cycle right on the machining system. In other words, the machining system, retrofitted with a sensor (i.e., a touch probe), is used to serve as a coordinate measuring machine while the workpiece is still on the machine. This concept certainly has merit since most CNC machining systems have control, scale, and structural integrity equal to or better than many DCC-CMMs.

The advantages of performing dimensional inspections on the same machining system are obvious: (1) it eliminates the need of moving the workpiece to a CMM; (2) it reduces the inspection cycle time; and (3) it eliminates realignment error should reworking the workpiece become necessary. The disadvantages, however, are (1) since the same machine frame is used for machining and inspection, if the machining system has any inherent errors (such as geometric errors) which affect the workpiece accuracy, it is incapable of detecting those errors in the inspection and (2) the machine will experience a large degree of thermal distortion caused by the internal heats.

In order to implement on-machine inspection, it is therefore necessary to first perform geometric accuracy evaluation of the machining system according to B5.54 Standards. All efforts should be made to ensure that the accuracy is maintained. Second, a machine thermal growth analysis should be performed to ascertain the limitation of the thermal distortion in inspection. In either case, a minimum rule of thumb of four times the accuracy tolerance should be applied. New techniques of thermal and geometric modeling and compensation of the machining system can be considered in order to achieve the inspection goals.

*Other Inspection Systems.* Other emerging inspection machines, such as the manually operated robotic measuring device, stereotriangulation measuring systems, and photogrammetry systems, are also gaining popularity in manufacturing. Although they may not offer the same types of accuracy and versatility as the previously mentioned system, they feature a new trend of inspection requirements — portability, agility, shop-floor hardiness, high-speed data acquisition, low cost, and powerful software capability.

## Mechatronics in Manufacturing

*Tai-Ran Hsu*

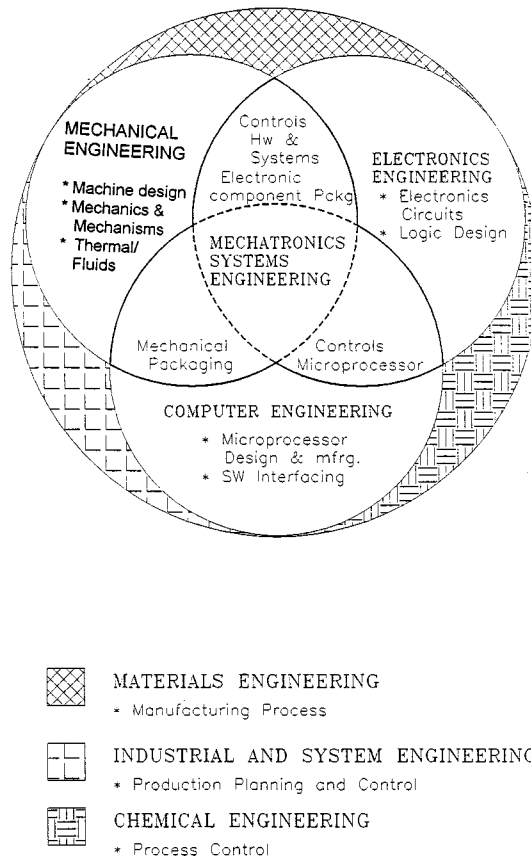

### Introduction

Mechatronics can be defined as: “A technology that involves the design, manufacture and production of *intelligent* products or engineering systems involving *mechanical* and *electronic* functions.” Mechatronics is a melding of two English words, *mechanical* and *electronics*. This terminology was first used by Yaskawa Electronic Corp. in Japan during the 1970s. The original notion of mechatronics involved the development and automated production of consumer products such as the Canon SLR autofocus camera (Gilbert, 1992). The application of this technology was soon extended to many other consumer electronic products that included video cassette recorders and the well-known Sony Walkman radios. The rapid advances of microprocessor and microcomputer technologies in the 1980s have broadened the applications of mechatronics to all smart products and systems, ranging from common consumer products to highly sophisticated space engineering equipment. In general, mechatronics systems engineering comprises a number of engineering disciplines. [Figure 13.3.9](#) illustrates interactions of the mechatronics systems engineering with other engineering fields.

### Elements of Mechatronic Systems Engineering

Most mechatronic products or systems consist of the following three modules:

1. *The sensing and control module*: This module involves hardware that includes electronic elements, electronic circuits, and the software that provides the commands and operation logics to all components in an automatic control systems. Basic hardware components include *sensors* (position, velocity, acceleration) including tactile, optical, and voice; *actuators* (linear, rotary, voice) driven by electrical, pneumatic, or hydraulic means; *drives* (DC/AC stepper or servomotors); *encoders* (optical or magnetic) and time counters. Other major components include signal processors, amplifiers, power suppliers, and A/D or D/A converters. Control software such as PLC, PID, and other application software are written in C, C++, LISP, FORTH, and RPL programming languages.
2. *Mechanical systems and kinematic linkages module*: The mechanical components in a mechatronic system provide the means to achieve the desired objectives of the product or the system. Principal mechanical components include gears, cams, chains, levers, shafts, pulleys, couplers, bearings, joints, and fasteners. These components are synthesized to construct mechanisms that perform the desired motion of end effects with accurate paths, positions, velocity, and accelerations.
3. *The microprocessors and computer interface module*: Microprocessors act as the brain of the mechatronic product or system. Principal functions of a microprocessor are to manage various instructions to all components such as transducers and actuators in the system, as well as I/O

**FIGURE 13.3.9** The relationship of various modules in a typical mechatronic device.

interfacing. These processors can also accept function commands from a microcomputer with specific control and applications software.

A block diagram that illustrates the relationship of various modules in a typical mechatronic system is presented in [Figure 13.3.10](#). One may imagine that the microprocessor and microcontroller module functions as the brain, and the sensing/control module and the mechanical systems module each function like the respective sensor-nerve system and the body and limbs in the human anatomy.

## 13.4 Design and Analysis Tools in Manufacturing

---

### Computer-Aided Design Tools for Manufacturing

*David C. Anderson*

#### Introduction

Computer-aided design (CAD) tools for manufacturing are computer programs that evaluate producibility of a product under development using computer models of the product and simulation models for manufacturing processes. Examples of such processes are assembly, casting, molding, stamping, forming, and inspection. The early stages of design are critical to the success of the final product since most of the final cost of a product is committed through decisions about the product's geometry and the materials that lead to the selection and planning of manufacturing processes and production facilities.

Concurrent engineering (CE) is a methodology for product development processes where the tasks are performed simultaneously based on "what if" decision-making processes. CE is a driving force behind the development of CAD tools for manufacturing.

#### CAD System and Manufacturing

One of the first and most prominent manufacturing applications of CAD system was the automated programming of numerically controlled (NC) machine tools. NC machines were developed in the 1950s, but their widespread use was hindered by the difficulty in writing the requisite NC programs, lists of coded cutting tool motions that directed the machine to cut the desired part. Computer programs that facilitated the generation of NC programs were among the first CAD tools for manufacturing. Early systems focused on profile cutting, generating cutter location data that described the 2D coordinates of the paths of cutting tools that would remove the material to create the final part. Three-dimensional NC programming capabilities are available in most CAD systems today. The user guides the generation of NC data by interactively selecting each surface to be machined and answering questions about tools, approach directions, and machining preferences.

#### Solid Models and Manufacturing

A key element of virtually all CAD tools for manufacturing is the need to interpret the CAD data according to manufacturing capabilities, requirements, and constraints. Generally, this interpretation involves determining the characteristic shapes in the CAD data related to the manufacturing process of interest and applying knowledge about the process to determine the manufacturing operations and parameters. Solid models are rigorous computer data structures that contain a complete, unambiguous representation of the nominal geometry of an object. Solid models and solid modeling operations, like the Boolean union, difference, and intersection of solids, enabled geometric computations about the design that were not possible with earlier CAD data. With solid modeling, the emphasis in CAD shifted from data for visual communication to product data models that could be used for more sophisticated computer analyses with more automation.

In solid models, geometric features can be described in a form more suitable for engineering and manufacturing applications. As a result, feature-recognition algorithms have become an important element of many CAD tools for manufacturing for translating CAD models into usable geometric data for design evaluations.

However, feature recognition has limitations because it is not possible to translate every solid model into a given set of features. Also, some applications of feature recognition require additional, nongeometric information. This information must be added to the CAD data before, during, or after the feature-recognition process. For example, part tolerance data are required for machining process planning but are not available in current CAD data. Feature-based design (FBD) was developed to overcome some of the limitations of feature recognition. Instead of deriving a features model from a solid model, FBD systems create the product model with features during the design process. Many FBD applications have

been demonstrated in the area of machining, and some commercial CAD vendors have incorporated these features into their systems.

FBD also has limitations. The features that are useful for one manufacturing process may not be useful for another. For example, a model made with cavity features, such as holes, slots, and pockets, provides ready-to-use data for machining planning. However, this model is inappropriate for sheet metal bending or welding processes that require an understanding of the bends and protrusions on a part, not its cavities.

### **Product Data Standards and Manufacturing**

The International Standards Organization (ISO) has developed the Standard for the Exchange of Product model data, STEP. In the U.S., the Integrated Graphics Exchange Specification (IGES)/PDES Organization (IPO) developed the Product Data Exchange Specification, PDES. These efforts merged and PDES was renamed Product Data Exchange using STEP, which is now the American National Standard for STEP. STEP became the international standard (ISO 10303) in March 1994.

STEP is organized as a series of “parts” that are developed and published separately. The parts are organized into numerical series: description methods (parts 11 to 20), integrated resources (parts 41 to 200), application protocols (parts 201 to 1200), abstract test suites (parts 1201 to 2200), implementation methods (parts 21 to 30), and conformance testing (parts 31 to 40). The product information is specified in a formal specification language, EXPRESS, which is documented in Part 11. Part 1 is an overview of the entire standard.

The STEP application protocols (APs) are important to CAD tools for manufacturing. These are the implementable portion of the STEP standard. Each AP draws upon integrated resources and adds specific constraints, relationships, and attributes to meet the information requirements of a particular application. It is expected that several hundred APs may be developed for many different industrial applications.

### **Design for “X” Tools**

Many CAD tools for manufacturing belong to a class of programs described as “design for x,” where “x” signifies an application area, such as design for assembly or design for castability. The phrase “design for manufacturability” (DFM) can be considered as a specialization of design for x in which all the applications are manufacturing. Generally, DFM applications are computer programs that perform computations to analyze the producibility of a product with respect to a specific manufacturing process or set of processes. The format of the design data representing the product required by the program varies greatly. The program then provides an evaluation of the suitability of the design according to this domain. The form of this evaluation also varies with each program.

DFM programs act as “manufacturing experts” that provide qualitative, and perhaps quantitative, information about potential problems in a design based on predefined knowledge about a manufacturing process. The programs emulate the process done by human experts, examining the design data and reporting any problems based on experience. Many efforts are based on expert systems technology from the field of artificial intelligence (AI). The searching is performed through the facilities of an AI language, such as PROLOG or LISP, or using an expert system “shell,” a preprogrammed generic expert system. Design data are first translated into a knowledge base, the AI version of a database, containing facts and rules. In a sense, the detailed design data are made into logical data that can be processed using AI methods. The program computationally searches the design data for data patterns that match problem conditions represented in the knowledge base of the program. The problem conditions are computer representations of design data that are known to cause manufacturing difficulties for a given process. For example, a “design for injection molding” program may report that an internal corner radius in a geometric model of a part is too small and may cause problems in the mold. In some cases, the program provides a quantitative evaluation of the design, or producibility index. This provides a convenient numerical comparison between two competing designs.

**Tools for Manufacturing Process Planning**

*Tien-Chien Chang*

**Introduction**

Process planning prepares a production documentation which specifies the operations and operation sequence necessary to manufacture a product. Process planning is defined as an act that determines the manufacturing operations, operation sequence, and resources required to make a product. In the process domain, there are machining process planning, welding process planning, EDM process planning, forming process planning, etc. In the product domain, there are mechanical part process planning, mechanical assembly process planning, and electronics assembly process planning. The input to a process planning system (or a human process planner) can be an engineering drawing, a CAD model, or a three-dimensional solid model. While most human planners prefer an engineering drawing on paper or in electronic form, process planning systems usually use CAD models.

The result of the process-planning activity is a “process plan” (see Figure 13.4.1), also called route sheet, operation sheet, or operation planning summary. It can be as aggregate as a list of work center identification numbers or as elaborate as a 50-page document with setup drawings, tool specifications, operation time estimates, etc.

**FIGURE 13.4.1** A process plan.

Since the information on the process plan is used in scheduling the production and controlling the machine, the production efficiency and the product quality are affected.

### Manual Process Planning

Process planning involves several or all of the following activities:

- Selection of machining operations
- Sequencing of machining operations
- Selection of cutting tools
- Selection of machine tools
- Determination of setup requirements
- Calculations of cutting parameters
- Planning tool path and generation of NC part programs
- Design of jigs and fixtures

The details incorporated in a typical process plan usually vary from industry to industry. It depends on the type of parts, production methods, and documentation needs. A process plan for a tool room-type manufacturing environment typically relies on the experience of the machinist and does not have to be written in any great detail. In fact, the instruction “make as per part print” may suffice. In typical mass-production-type industries, the process-planning activity is embodied in the transfer and flow lines used for manufacturing component parts and assembly. For metal-forming-type manufacturing activities, such as forging, stamping, die casting, sand casting, injection molding, etc., the process-planning requirements are embedded directly into the design of the die/mold used, where most process-planning activity is fairly simple. A process planner must

- Be able to understand and analyze part requirements
- Have extensive knowledge of machine tools, cutting tools, and their capabilities
- Understand the interactions between the part, manufacturing, quality, and cost
- Possess analytical capabilities

### Tolerance Charting

During process planning it is important to ensure that the setup and operation sequence will yield a satisfactory part. Tolerancing charting (Figure 13.4.2) has been used to help in allocating process tolerances and verifying the operation sequence. A tolerance chart analyzes one dimension at a time. In a tolerance chart, the top is the part drawing. Dimensions and tolerances are presented with the geometry. Dashed lines show the stock boundary. From the features of the part and the stock, extension lines are drawn to the body of the chart. The section below the drawing shows the critical dimensions and tolerances. These dimensions and tolerances must be satisfied after the processes are complete. Following the process sequence, each operation is listed in the third section of the chart. A line is drawn from the reference surface of a setup to the cut surface. For example, in operation 10, the raw stock boundary at the left is the reference surface. The second surface from the right-hand side is created by this operation. From the chart, one can calculate the resultant tolerances. The results are compared with the blueprint tolerance.

Although traditionally a tolerance chart is implemented on paper and through a fixed procedure, it can also be implemented in a computer. The process tolerance stack-up may be used to verify the design specification and select the appropriate processes and sequences.

### Computer-Aided Process Planning

There are two basic approaches to computer-aided process planning — variant and generative. The variant approach is signified by the terminology used by the computer to retrieve plans for similar

FIGURE 13.4.2 Tolerance chart.

components using table lookup procedures. The human process planner then edits the plan to create a “variant” to suit the specific requirements of the component being planned. Creation and modification of standard plans are the process planner’s responsibility. The generative approach generates a plan for each component without referring to existing plans. Generative-type systems can perform many functions in a generative manner, while the remaining functions are performed with the use of humans in the planning loop.

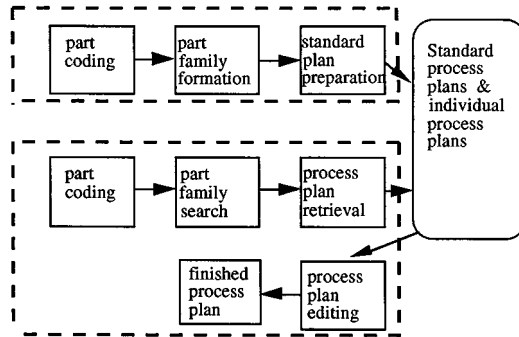

**Variant Process Planning**

The variant approach to process planning was the first approach used to computerize the planning techniques. It is based on the concept that similar parts will have similar process plans. The computer can be used as a tool to assist in the identification of similar plans, retrieving them and editing the plans to suit the requirements for specific parts.

In order to implement such a concept, part coding and classification based on group technology is used as a foundation. Individual parts are coded based upon several characteristics and attributes. Part families are created of “like” parts having sufficiently common attributes to group them into a family. This family formation is determined by analyzing the codes of the part spectrum. A “standard” plan consisting of a process plan to manufacture the entire family is created and stored for each part family. The development of a variant-process-planning system has two stages: the preparatory stage and the production stage (Figure 13.4.3).

During the preparatory stage, existing components are coded, classified, and later grouped into families. The part family formation can be performed in several ways. Families can be formed based on geometric shapes or process similarities. Several methods can be used to form these groupings. A simple approach would be to compare the similarity of the part code with other part codes. Since similar parts will have similar code characteristics, a logic which compares part of the code or the entire code can be used to determine similarity between parts.

Families can often be described by a set of family matrices. Each family has a binary matrix with a column for each digit in the code and a row for each value a code digit can have. A nonzero entry in the matrix indicates that the particular digit can have the value of that row, e.g., entry (3,2) equals one

**FIGURE 13.4.3** Variant-process-planning approach.

implies that a code x3xxx can be a member of the family. Since the processes of all family members are similar, a standard plan can be assigned to the family. The standard plan is structured and stored in a coded manner using operation codes (OP-codes). An OP-code represents a series of operations on one machine/workstation. For example, an OP-code DRL10 may represent the sequence center drill, change drill, drill hole, change to reamer, and ream hole. A series of OP-codes constitute the representation of the standard process plan.

Before the system can be of any use, coding, classification, family formation, and standard plan preparation must be completed. The effectiveness and performance of the variant-process-planning system depend to a very large extent on the effort put forth at this stage. The preparatory stage is a very time-consuming process.

The production stage occurs when the system is ready for production. New components can be planned in this stage. An incoming component is first coded. The code is then sent to a part family search routine to find the family to which it belongs. Since the standard plan is indexed by family number, the standard plan can be easily retrieved from the database. The standard plan is designed for the entire family rather than for a specific component; thus, editing the plan is unavoidable.

Variant-process-planning systems are relatively easy to build. However, several problems are associated with them., e.g.,

1. The components to be planned are limited to previously planned similar components.
2. Experienced process planners are still required to modify the standard plan for the specific component.
3. Details of the plan cannot be generated.
4. Variant planning cannot be used in an entirely automated manufacturing system, without additional process planning.

Despite these problems, the variant approach is an effective method, especially when the primary objective is to improve the current practice of process planning. In most batch-manufacturing industries, where similar components are produced repetitively, a variant system can improve the planning efficiency dramatically. Some other advantages of variant process planning are

1. Once a standard plan has been written, a variety of components can be planned.
2. Programming and installation are comparatively simple.
3. The system is understandable, and the planner has control of the final plan.
4. It is easy to learn and easy to use.

### Generative Approach

Generative process planning is the second type of computer-aided process planning. It can be concisely defined as a system which automatically synthesizes a process plan for a new component. The generative approach envisions the creation of a process plan from information available in a manufacturing database

without human intervention. Upon receiving the design model, the system is able to generate the required operations and operation sequence for the component.

Knowledge of manufacturing has to be captured and encoded into computer programs. By applying decision logic, a process planner's decision-making process can be imitated. Other planning functions, such as machine selection, tool selection, process optimization, etc., can also be automated using generative planning techniques.

A generative-process-planning system comprises three main components:

1. Part description
2. Manufacturing databases
3. Decision-making logic and algorithms

The definition of generative process planning used in industry today is somewhat relaxed. Thus, systems which contain some decision-making capability on process selection are called generative systems. Some of the so-called generative systems use a decision tree to retrieve a standard plan. Generative process planning is regarded as more advanced than variant process planning. Ideally, a generative-process-planning system is a turnkey system with all the decision logic built in. However, due to the differences among manufacturing shops, decision logics have to be customized for each shop.

The generative-process-planning approach has the following advantages:

1. Consistent process plans can be generated rapidly.
2. New components can be planned as easily as existing components.
3. It has potential for integrating with an automated manufacturing facility to provide detailed control information.

There is no fixed representation or procedure that can be identified with generative process planning. The general trend is to use a solid model CAD-based input and expert system or an object-oriented planner construct. Most of the research systems are of this type. A few commercial products can also be classified as generative.

## Conclusions

Process planning is a critical function in design and manufacturing. The quality of the product and the cost of production are affected by the process plan. A process plan incorporates information on the shop capability, resource requirement, best routing, etc. In order to produce a good process plan, a planner must be knowledgeable in both the manufacturing practices and the current shop status and capabilities. At this moment most computerized planners are still based on data retrieval and database lookup. As the information technology is further developed and we have better understanding of process capabilities, integrated planning systems will evolve.

## Simulation Tools for Manufacturing

*Hank Grant*

### Introduction

Digital simulation uses a mathematical model to represent a real or hypothetical physical system. A computer simulation model of a physical system provides a laboratory in which alternative designs can be explored and analyzed. The model, executed on the computer, is a software replica of the manufacturing system and is controlled so that the behavior of the system can be studied and analyzed. Decisions can be made concerning production alternatives. For example, adding a new lathe can be considered without disrupting the actual physical system.

Simulation depends on describing a system in terms acceptable to the computer language used. To do this, it is necessary to have a *system-state description*, which is typically characterized by a set of state variables included in the computer program that make up the simulation model.

### Types of Simulation Models

Simulation models are typically classified into three types: discrete event, continuous, and combined. Simulation software has been designed to address each of these types of models.

*Discrete Event.* Discrete event simulation is used to model systems when there are specific events in time when the variables of the system may change in values. The mechanics of those changes must be well known and easily characterized. The behavior of the system is represented by the behavior of individual objects of interest called *entities*. The simulation model characterizes the behavior of these entities as they move through the system in simulated time.

Discrete events are points in time where the characteristics of an entity may change and where the state variables of the system may change. For example, when a customer arrives for service, the state of the system may change (number in the system, status of the server, etc.). The modeling of systems using this approach consists of developing descriptions of the events and how they cause the state variables to change and the entities to be manipulated.

The individual events may not always be predictable, and stochastic elements may be present in the operation of the system. For example, the time between arrivals of customers to the system may be a random variable. Simulation languages have many tools to support random variation in models.

A special kind of discrete event model is a *network model*. Network models use a standard set of symbols to represent the flow of entities in the system. They are graphical in nature, and are very useful communication vehicles as well as very powerful in building simulation models quickly and easily. There are several languages available that include network modeling capabilities and they are described below.

*Continuous.* *Continuous simulation* is an approach that is popular among engineers and economists. The main building blocks of this approach are as follows (Pidd, 1994).

*Aggregated variables:* Instead of a concern with individual entities, the main concern is with the aggregated behavior of populations. For example, the changing sales of a product through time.

*Smooth changes in continuous time* rather than focusing on individual events, where the stress is on the gradual changes which happen as time progresses. Thus, just as the graph of a variable might be smooth, the aim is to model the smooth changes of the variable by developing the suitable continuous equations.

*Differential or difference equations:* The model consists mainly of a set of equations which define how behavior varies through time; thus, these tend to be differential equations or, in simpler cases such as system dynamics, difference equations.

Nature does not present itself labeled neatly as discrete or continuous; both elements occur in reality. Modeling, however, as mentioned above, involves approximation, and the modeler must decide which of these approaches is most useful in achieving the desired aim of the simulation.

*Combined Discrete Event/Continuous.* In some cases, both approaches are needed and the result is a mixed discrete-continuous simulation. An example of this might be a factory in which there is a cooking process controlled by known physics which is modeled by continuous equations. Also in the factory is a packing line from which discrete pallets of products emerge. To model the factory will require a mixed approach.

### **Modeling Languages**

Specifically designed computer simulation languages provide many features for managing the updating of the state variables and advancing time. They also provide features for recording system performance statistics and for generating random numbers to introduce system randomness.

The lowest level of computer language typically used is FORTRAN or BASIC. This requires that the entire simulation model be coded, which is labor-intensive. High-level languages, such as SLAM, SIMSCRIPT, and GPSS, facilitate simulation because they provide subroutines for time advancement, entity maintenance, and statistic collections. Higher-level simulation languages are designed for special purposes; MAP/1, SPEED, and MAST are three designed for the simulation of manufacturing systems.

Some simulation languages can produce animations. This permits the simulation to be illustrated graphically on a computer terminal so that the analyst can see the system in action and observe its interactions and behavior, a visual function beyond the scope of standard reporting technique. For example, TESS (a software program) provides animation, as well as model-building and output analysis capabilities, for the SLAM simulation language.

The following discussion by Banks (1994) provides an overview of the primary languages available.

Applications of simulation exist in many arenas such as manufacturing, material handling, health services, military decision support, natural resources, public services, transportation, and communications, to mention a few.

These simulation applications are usually accomplished with the use of specially developed simulation software. This tutorial describes the software in two categories. The first of these is software for general purposes. This type of software can solve almost any discrete simulation problem. In this section, five products, GPSS/H™, GPSS/World™, SIMAN V', SIMSCRIPT II.5', and SLAMSYSTEM', will be discussed to provide a feel for this type of software.

*GPSS/H.* GPSS/H is a product of Wolverine Software Corporation, Annandale, VA (Smith and Crain, 1993). It is a flexible, yet powerful tool for simulation. It provides improvements over GPSS V that had been released by IBM many years earlier. These enhancements include built-in file and screen I/O, use of an arithmetic expression as a block operand, interactive debugger, faster execution, expanded control statement availability, and ampervariables that allow the arithmetic combinations of values used in the simulation. The latest release of GPSS/H is version 2.0. It added a floating point clock, built-in math functions, and built-in random variate generators. Options available include Student GPSS/H, Personal GPSS/H within the 640K memory limit, and GPSS/H 386 providing unlimited model size.

*GPSS World.* GPSS World, from Minuteman Software, is a complete redesign of GPSS/PC™ (Cox, 1992). It is designed as a high-power environment for simulation professionals. It includes both discrete and continuous simulation. Its features include interactivity, visualizability, and configuration flexibility. It utilizes 32-bit computing, virtual memory, preemptive multitasking, symmetric multiprocessing, and distributed simulation. Highlights include drag-and-drop model building, 512 megabytes of virtual

memory for models, point-and-shoot debugging, an embedded programming language, built-in probability distributions, multiple data types, and many other improvements to GPSS/PC.

The GPSS World family is a set of three software products including:

1. GPSS World is the center of the family. This self-contained modeling environment includes local Simulation Server™ capabilities.
2. Simulation Server provides simulation services on a remote networked computer. It does not include a model-building user network.
3. Simulation Studio provides hierarchical modeling and user-drawn simulation capabilities.

There is an enhanced memory version of GPSS/PC that is also available. It allows access of up to 32 megabytes of memory.

*SIMSCRIPT II.5.* SIMSCRIPT II.5 from CACI Products Company is a language that allows models to be constructed that are either process oriented or event oriented (Russell, 1993). The microcomputer and workstation version include the SIMGRAPHICS animation and graphics package. SIMSCRIPT can be used to produce both dynamic and static presentation-quality graphics such as histograms, pie charts, bar charts, levels of meters and dials, and time plots of variables. Animation of the simulation output is also constructed using SIMGRAPHICS. SIMGRAPHICS can be used also to produce interactive graphical front ends or forms for entering model input data. An input form may include such graphical elements as menu bars with pull-down menus, text or data boxes, and buttons that are clicked on with a mouse to select an alternative. The graphical model front end allows for a certain set of modifications to the model to be made without programming, facilitating model use by those who are not programmers.

*SIMAN V.* SIMAN V from Systems Modeling Corporation is a general-purpose program for modeling discrete and/or continuous systems (Glavach and Sturrock, 1993; Banks et al., 1995). The program distinguishes between the system model and the experiment frame. The system model defines components of the environment such as machines, queues, and transporters and their interrelationships. The experiment frame describes the conditions under which the simulation is conducted, including machine capacities and speeds and types of statistics to be collected. “What-if” questions can usually be asked through changing the experiment frame rather than by changing the model definition. Some important aspects of SIMAN V are as follows:

1. Special features that are useful in modeling manufacturing systems include the ability to describe environments as work centers (stations) and the ability to define a sequence for moving entities through the system.
2. Constructs that enable the modeling of material-handling systems including accumulating and nonaccumulating conveyors, transporters, and guided vehicles.
3. An interactive run controller that permits break points, watches, and other execution control procedures.
4. The ARENA environment that includes menu-driven point-and-click procedures for constructing the SIMAN V model and experiment, animation of the model using Cinema, the input processor that assists in fitting distributions to data, and the output processor that can be used to obtain confidence intervals, histograms, correlograms, and so on. (More aspects of the ARENA environment are discussed later.)
5. Portability of the model to all types of computers.

*SLAMSYSTEM.* SLAMSYSTEM, from Pritsker Corporation, is an integrated simulation system for PCs based on Microsoft Windows™ (Pritsker, 1986; O’Reilly, 1993). All features are accessible through pull-down menus and dialog boxes and are selected from the SLAMSYSTEM Executive Window. A SLAMSYSTEM project consists of one or more scenarios, each of which represents an alternative system configuration. A project maintainer examines the components of the current scenario to determine if any of them have been modified, indicates whether or not tasks such as model translation should be performed,

and allows the user to accomplish these tasks before the next function is requested. SLAMSYSTEM allows multiple tasks to be performed in parallel while the simulation is operating in the background.

Some of the features of SLAMSYSTEM are as follows:

1. Models may be built using a graphical network builder and a forms-oriented control builder, or text editor. When using the first method, a network symbol is selected with the mouse, then a form is completed specifying the parameters for that symbol. The clipboard allows many other operations such as grouping one or more symbols and placing them elsewhere on the network.
2. Output analysis includes a “report browser” that allows alternative text outputs to be compared side by side. Output may be viewed in the form of bar charts, histograms, pie charts, and plots. Output from multiple scenarios can be displayed at the same time in bar chart form. By using the Windows environment, multiple output windows can be opened simultaneously.
3. Animations are created under Windows using the facility builder to design the static background and the script builder to specify which animation actions should occur when a particular simulation event occurs. Animations can be performed either concurrently or in a postprocessing mode. Two screens can be updated simultaneously and up to 225 screens can be swapped into memory during an animation.
4. SLAMSYSTEM was designed to be used in an integrated manner. For example, historic data may be read to drive the simulation. CAD drawings may be loaded. Output charts and plots created by SLAMSYSTEM may be exported via the clipboard to other applications.

The newest release of SLAMSYSTEM is version 4.0. Some of its unique features include the following:

1. Multiple networks in a single scenario: Networks can be constructed in sections and combined at run time. The sections can be reused in future models.
2. New output graphics: These graphics support three-dimensional X-Y grids and displaying of point plot data.
3. Direct interface to SimStat (product of MC<sup>2</sup> Analysis Systems): These files may be loaded for advanced statistical analysis.
4. OS/2 metafiles for graphics: The OS/2 metafile format can be read for animation backgrounds or icons.

## Conclusion

Simulation is a powerful approach to modeling manufacturing systems in that many complex and diverse systems can be represented. Simulation can predict system performance measures that are difficult to assess without a model. It is a proven, successful tool and has been in use since the 1950s. The current languages take advantage of the capabilities of today’s microprocessors and provide the user with the needed on-line support for model development, management, and analysis.

## Tools for Intelligent Manufacturing Processes and Systems: Neural Networks, Fuzzy Logic, and Expert Systems

*Tien-I. Liu*

### Introduction

Starting in the 1980s, researchers and practitioners became increasingly interested in intelligent machines and intelligent manufacturing. The goal is to model the skills and expertise of professionals so that machines and manufacturing systems can possess some of the characteristics of human intelligence. Three techniques, neural networks, fuzzy logic, and expert systems, have been widely used in manufacturing. This section describes the principles and functions of these tools. Examples in applying these tools to manufacturing applications are highlighted as well.

### Neural Networks

Neural networks consist of a set of nodes which are nonlinear computational elements. The pattern of connectivity between nodes, known as weights, can be modified according to some preset learning rule. The knowledge of the networks is stored in their interconnections (Kohonen, 1986).

Since neural networks are parallel distributed processing, they have the following advantages:

1. They are adaptive and can learn from experience.
2. The network can be refined at any time with the addition of new training data.
3. Various model architectures can be used.
4. They can compute very quickly and thus they are very suitable for real-time applications.
5. They can be used for analyzing large amounts of data to determine patterns that may predict certain types of behavior.
6. They can capture the complexities of the process, including nonlinearities, even if the dynamics of the process is unknown.
7. They can make decisions based upon incomplete and noisy information.
8. They degrade gracefully even when parts of the structure have been destroyed.

Neural networks are best at performing the types of tasks which need human perception. These tasks do not have exact answers, e.g., classification and trend analysis. A typical example of such problems is machine diagnosis. An experienced mechanic can point out what is wrong with an automobile by standing beside the car and listening to the sound of the running engine. Another example is character recognition. Any person who is familiar with alphabets can easily identify the letter “A” in any of various typefaces or handwritten scripts. In both cases it is practically impossible to develop a set of if–then rules to let a computer to do the job. These tasks are also difficult to program using standard computer techniques.

*Applications of Neural Networks.* Many electronics and computer companies have put considerable effort into neural network development. IBM has announced a neural network development package for its computer; Intel Corporation has developed a microchip that supports this technology. Japanese companies such as Fujitsu, Hitachi, Mitsubishi, and Sumitomo Heavy Industries are also working in this field.

A bomb-detection machine which uses neural network technology to detect plastic explosives hidden in baggage has been developed. This machine has been installed in several airports. Neural networks have also been applied to ensure the operation of an industrial power distribution substation. It has replaced a conventional mechanical system and improved the performance by greater than an order of magnitude.

Integrating sensors with neural networks for monitoring and diagnostic purposes can enhance production reliability, prevent potential problems caused by abnormal conditions, and maintain high product quality in the factory (Liu and Iyer, 1993). The applications of neural networks for monitoring and diagnostic purposes have been used with ball-and-roller bearings, turning processes, milling processes, drilling processes, tapping processes, glass furnaces, etc. The results are very successful (Liu and Anatharaman, 1994).

Neural networks have also been used in the image processing for computer vision and speech-recognition systems (Badal, 1993). They also are used for the control of machines and processes. The neural network controller is capable of on-line learning of the system dynamics and then taking adequate action to achieve the predetermined goal. They also can be used to tune the gain of control systems.

### Fuzzy Logic

The theory of fuzzy sets has been developed as a methodology for the formulation and solution of problems which are too complex or too ill defined to be solved by traditional techniques. In fuzzy logic, the membership in a set is not either 0 or 1; instead it is a value between 0 and 1. Membership functions span some problem domain, such as length or weight, and show the membership for each value of the problem domain. Membership functions are subjective evaluations and can be represented by many kinds of curve. However, the membership function cannot be assigned arbitrarily. The formulation of the membership function should be based upon the professional feeling and physical understanding of the problem. Let  $S = \{s\}$  represent a space of objects. Then a fuzzy set  $X$  in  $S$  is a set of ordered pairs

$$X = \{s, f_x(s)\}, \quad s \in S(1)$$

where  $f_x(s)$  is the grade of membership of  $s$  in  $X$  and  $f_x(s)$  is a number in the interval (0,1).

Fuzzy mathematics, which consists of precise rules to combine vague expressions, such as “very high” and “somewhat heavy,” has been developed (Kandel, 1986). Generally speaking, fuzzy logic systems have the following advantages:

1. They are inherently flexible.
2. They are robust to noisy or missing data, unexpected disturbances, and errors in problem modeling.
3. They are suitable to deal with problems for which knowledge is approximate or problems which are so complex that it is difficult to develop an adequate mathematical model.
4. They usually are energy efficient.

*Applications of Fuzzy Logic.* Fuzzy mathematical techniques are very suitable for the control of machine tools, robots, and electronic systems (Mamdani, 1993). They are also applicable to image understanding for computer vision and pattern classification for the monitoring and diagnosis of manufacturing processes (Du et al., 1992).

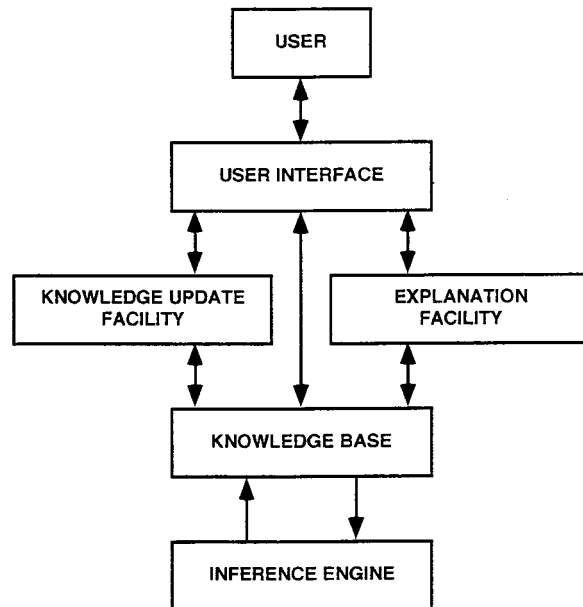

The very first application of fuzzy logic was the control of the fuel-intake rate and gas flow of a rotating kiln used to produce cement. Since then, it has been used to control many automated manufacturing processes. Fuzzy logic has resulted in significant improvements to many commercial products,

such as cameras and air conditioners. Although fuzzy logic was developed in the U.S., most of the action is in Japan. The most impressive application is a subway system operated by a fuzzy computer. It was installed in the 1980s by Hitachi at Sendai, about 200 mi north of Tokyo, Japan. This system is more than 10% energy efficient and is so smooth that passengers do not need to hang onto straps.

At AT&T Bell Laboratories, Dr. M. Togai and Dr. H. Watanabe developed the very first fuzzy logic processing chip in 1985. NASA is developing fuzzy controllers to help astronauts pilot the space shuttle in earth orbit. In the U.S. the interest in applying fuzzy logic is growing continuously.

### Expert Systems

An expert system is a computer system which possesses the capability of a human expert. An expert system has the following five essential parts (Figure 13.4.4):

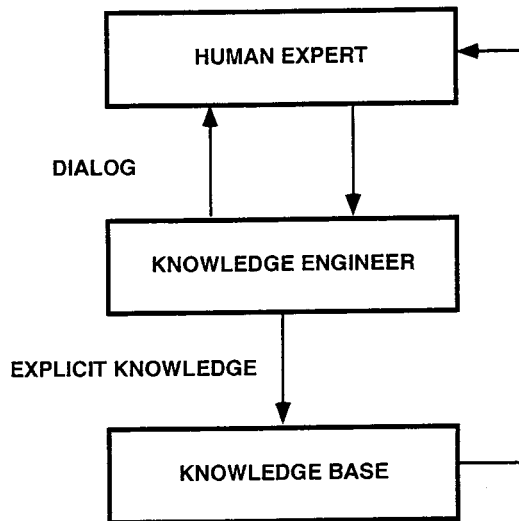

**FIGURE 13.4.4** Typical expert system architecture.

1. *User Interface.* This module is the interface between the user and other parts of the expert system.
2. *Knowledge Base.* The knowledge about solving specific problems is stored in the knowledge base of an expert system. The process of building the knowledge base is called knowledge engineering and is done by a knowledge engineer (Figure 13.4.5). Knowledge engineering refers to the acquisition of knowledge from a human expert or other source and the coding of it into the expert system. The knowledge base usually consists of rules and facts. Rules are made up of English-like sentences or clauses. Rules are often defined using an if-then syntax that logically connects one or more antecedent clauses with one or more consequent clauses as follows:

IF antecedent THEN consequent

A rule says that if the antecedent is true, then the consequent is also true. The antecedent and consequent of rules refer to a specific fact that describes the state of the world. On the other hand, each fact is a single sentence that describes some aspect of the state of the world.

3. *Inference Engine.* The inference engine can infer new knowledge from existing knowledge stored in the knowledge base. Two general inference approaches are commonly used: forward chaining and backward chaining. Forward chaining is the reasoning from facts to conclusions resulting

**FIGURE 13.4.5** Knowledge engineering.

from those facts. Backward chaining involves reasoning in reverse from a hypothesis to the facts which support the hypothesis.

4. *Knowledge Update Facility.* The knowledge in many fields, including engineering and manufacturing, changes with time. The expert system can be updated through this facility.
5. *Explanation Facility.* Just like a human expert can explain how a specific conclusion has been drawn, the explanation facility can explain its reasoning to enhance the credibility of an expert system.

Expert systems are quite different from conventional programs because the problems usually have no algorithmic solution and rely on inferences to achieve a reasonable solution. In other words, the expert system is very suitable to solve problems which require heuristic rules. These heuristic rules can be stored in the knowledge base.

Expert systems have the following advantages as compared with the human expert:

1. They are steady and unemotional and have high reliability. Therefore, errors are reduced.
2. They have high availability. Users can get answers any time.
3. The expert system can be installed and used at multiple sites.
4. They can explain how a conclusion has been reached. Thus, the users feel comfortable working with expert systems.

Expert systems can help people solve problems. They can free the human expert from the routine job to do other work. Hence, they can increase efficiency and reduce cost.

*Applications of Expert Systems.* Expert systems have been used in many fields. There are many commercialized expert systems running on different computer platforms which help professionals in various fields, enhancing efficiency and productivity greatly.

Manufacturing, assembly, quality, reliability, and cost need to be taken into consideration in the early stage of product design. Expert systems have been developed for DFM, design for assembly (DFA), design for quality and reliability, product cost estimation, etc. These expert systems can be integrated with the existing CAD/CAM systems (Liu et al., 1995). Many expert systems have also been built and used in the areas of facility design, production planning and control, computer-aided process planning, material handling, quality control, equipment maintenance and repair, and real-time control (Alto et al., 1994). In simple words, design and manufacturing work can be upgraded from an experience-based to a science-based function by using expert systems.

## Conclusion

Neural networks, fuzzy logic, and expert systems are the way of the future. They can make machines and manufacturing processes much smarter. Applying these techniques can lead to the realization of a fully automated factory in the future.

## Tools for Manufacturing Facilities Planning

*J. M. A. Tanchoco, Andrew C. Lee, and Su-Hsia Yang*

### Introduction

The main function of facility planning is the design of efficient flow of products from raw material to finished goods. It is one of the most important determinants of operating efficiency and production cost. Traditionally, the facility-planning problem is divided into three areas, namely, group technology (GT), material handling, and facility layout (see [Figure 13.4.6](#)). GT, which is closely related to cellular manufacturing, is usually defined as the grouping of dissimilar machines in close vicinity. Each group or cell is dedicated to the production of one or more parts families. The parts in the family are similar in their processing requirements (Wemmerlov and Hyer, 1989). Two of the most fundamental elements in facility planning are the facility layout and the material-handling system.

Facility layout positions the workstations around the fixed product based on the processing sequence. In a product layout, machines are arranged according to the processing sequence of the product, e.g., the assembly of automobiles, certain electronic products, etc. The machines are located so as to provide smooth and logical flow of material. In a group layout, also referred to as a cellular layout, products are grouped into logical product families. All machines which perform similar operations are grouped together in the process layout. A process layout is characterized by a high degree of flexibility and machine utilization. Regardless of the type of facility, a detailed layout should not be designed without giving serious consideration to material-handling requirements. The choice of material-handling methods and equipment is an integral part of the layout design. The facility layout design component performs two basic functions. The first function is to decide how to locate cells with respect to each other. The objective is to minimize either the total material flow distance or transportation time. The second function is to resolve the machine location and orientation relative to each other within the cell. The constraints in layout design or facility structure could prohibit the placement of the cells or machines in some

**FIGURE 13.4.6** Facilities-planning framework components.

locations, thus changing the machine compositions of the cells. The resolution from this design problem has a significant impact on the distance that material has to be moved.

Material handling performs a critical function in modern dynamic manufacturing systems. The transportation of materials within a production system is often accomplished with limited resources, e.g., conveyors, forklift trucks, or automated guided vehicles (AGVs). Such transfer mechanisms not only deliver material in a timely fashion, but also provide temporary storage capacity. These limited resources require a capital investment, which increases the overall production costs. Excess transportation capability represents expenditures that are not accompanied by increased value. Insufficient capacity, on the other hand, can adversely affect production by delaying the delivery of material, thus reducing the total production volume. Material handling is generally considered as a non-value-adding activity. However, one can argue that material handling adds time and space value by making the material available and ready for processing. The material handling has three functions. First, the flow path design selects the route that material transfers from cell to cell or from machine to machine. Limited by the cost of remodeling, the existing plant configuration (such as the aisle width) might not be able to accommodate the traffic flow. Therefore, considerations must be given to the overall facility layout and building structure. The second function is to locate the pickup and delivery stations along the flow path. Along with the facility layout and flow path design, it is one of the most important determinants of the operating cost of material handling. Finally, the best combination of material-handling equipment is determined. Because of the complex, ill-structured, and experience-based nature of the problem, the decisions for choosing material-handling equipment tend not to be based on rigorous criteria. However, the designers must recognize that there is an appropriate level of technology for every application that will meet the combined need for maximum handling efficiency and acceptable cost.

**Decision Factors for Facilities Planning**

The effectiveness of a facility-planning system depends on the careful integration of GT, facility layout, and the material-handling system.

*Group Technology.* Mitrofanov (1959) is recognized as the first person to introduce the concept of GT and machine grouping. Since then, a number of researchers have developed techniques for machine grouping and part family formation. In general, these techniques can be categorized as follows:

1. *Machine-Component Matrix* (McAuley, 1972; King, 1980; McCormick et al., 1972): The main idea behind this approach is to delineate cells by grouping binary entries of a machine–component incidence matrix into fuzzy blocks along the matrix diagonal.

2. *Mathematical Programming Formulation* (Kusiak et al. 1986; Askin and Standridge, 1993): In this approach, a large, combinatorial mixed integer programming formulation is usually required to model the problem.
3. *Graph-Based Formulation/Partitioning* (Rajagopalan and Batra, 1975; Faber and Carter 1986): In this approach, the machine-part matrix is represented by a bipartite, transition, or boundary graph. Then, it is solved using graph theoretic clustering methodology.

*Facility Layout.* The facility layout problem has been formulated as a quadratic assignment problem (QAP). The objective function for this type of formulation is to minimize the total material-handling cost. Given the complexity of the QAP formulation, the size of problems which could be solved by optimal methods is very limited. Thus, heuristic algorithms are more suitable. These heuristics can be classified into two major groups. The first group is called construction algorithms (Seehof and Evans, 1967; Lee and Moore, 1967; Foulds and Giffin, 1985; Hassan and Hogg, 1991). The main idea behind these methods is to build the layout by adding one more block (a cell or a department) to a partial block layout until all blocks have been located. The methodology requires two steps: a selection step and a placement step. The selection step determines the order by which the blocks enter the layout, while the placement step selects the location of the new block to enter the layout relative to the blocks that are already in the layout. The objective is to maximize some kinds of performance criteria, e.g., total closeness rating. Graph theoretic methods have been applied as a solution methodology for this approach.

The second group of the layout heuristics is called improvement algorithms. This approach starts from an initial layout, and improvements are made by successive pairwise interchanges of blocks. The general form of an improvement algorithm consists of the following steps: (1) select a pair of activities, (2) estimate the cost of interchange, (3) exchange if the total cost is reduced, and (4) repeat until no more improvement can be made. This category of heuristics includes the computerized relative allocation of facilities technique (CRAFT) of Armour and Buffa (1963) and Buffa et al. (1964) and the methods of Hillier (1963), Fortenberry and Cox (1985), and Co et al. (1989).

Recognizing the weaknesses of both construction and improvement algorithms when applied separately, Golany and Rosenblatt (1989) proposed a hybrid method that takes advantages of both construction and improvement algorithms. They use the layout resulting from the construction algorithm as the initial layout and improve upon it using an improvement algorithm. Since most of the heuristics for facility layout are based on the “greedy approach,” the solution is very sensitive to the initial layout. The final layout given by the algorithm may not be the best.

*Material Handling.* Material handling involves moving, storing, and controlling the flow of materials. There are several components, such as the flow path design, the locations of pickup and delivery stations, and the material-handling equipment selected, that have significant effects on the overall effectiveness of the material-handling system. The objective of flow path design is to determine the best “street network” that transporters pass through when parts are moved from one machine to the next. It is one of the major determinants in the calculations of travel times, operating expenses, and installation costs of the material-handling system. There are numerous types of flow path network configurations. The most widely adopted flow path design is the conventional flow network. It is usually a unidirectional flow network where any cell boundary is used as part of the flow path. In a unidirectional network, one has to determine the flow direction for each aisle. Its flexibility, reliability, and efficiency have made this type of network a popular choice especially when AGVs are used. In comparison, the potential of using a bidirectional flow network could make the system more efficient (Egbelu and Tanchoco, 1986). The same authors also developed guidelines for the use of a single-lane bidirectional flow network. However, the advanced hardware requirements and complicated system controllers are viewed negatively.

A single-loop flow path network can be found in many flexible manufacturing systems. The entire flow path design is made up of a single loop. This type of network can potentially minimize some of the problems associated with a conventional flow network. Congestion is inherently low and the operating rules are simple. It also has relatively low initial investment and maintenance costs.

Recently, a new flow path network configuration, a segmented flow topology (SFT), was developed by Sinriech and Tanchoco (1994). It is comprised of one or more zones, each of which is separated into nonoverlapping segments. Each segment is serviced by a single bidirectional material-handling device. Transfer buffers are located at both ends of each segment. The flow structure in each zone is determined by the logical flow requirements and by the existing aisle network. The SFT provides a simple flow structure and control system. The research also suggested that it can achieve a higher throughput capability compared to other material flow path network configurations.

The locations of pickup and delivery stations have generally been considered as a secondary issue in the design phase of facility layout and a material-handling system. Yet it can have detrimental effects on the costs of material handling and the a machine layout configuration. In a study by Warnecke et al. (1985), they confirmed that the actual pickup and delivery station flow distance is much more representative than taking the rectilinear distance between the centers of machine blocks. Since then, several design procedures have been proposed to find the optimal location of material-transfer stations. Montreuil and Ratliff (1988) suggested a systematic methodology for locating pickup and delivery stations within a facility layout using multifacility location theory. The objective function is to minimize the sum of the rectilinear distance traveled by all intercellular flows, given the boundary regions on station location. Luxhoj (1991) developed a two-phase design procedure that is suitable for the spine layout where the active flow lines are well defined.

In terms of material-handling equipment selection, there is a large variety of equipment types available with their own special functions and characteristics. Each equipment type has its own capability and limitations. Some of these characteristics are difficult to quantify. The integrated nature of the manufacturing systems complicates the material-handling selection problem. The problem was first addressed by Webster and Reed (1971). The procedure they suggested initially assigns material-handling equipment to departmental moves based on cost alone. Then, move assignments are interchanged to seek improvement in equipment utilization and total cost. Hassan et al. (1985) reformulated Webster and Reed's model as an integer programming model with the objective of minimizing the total operating and capital costs of the selected equipment. Due to the combinatorial nature of the problem, it is solved using a construction heuristic that exploits some similarities to both knapsack and the loading problems. Material Handling Equipment Selection System (MATHES) was developed by Fisher et al. (1988). MATHES is a rule-based system for the selection from 24 different types of material-handling equipment.

## Conclusion

The framework discussed in this section provides an alternative perspective from the material flow viewpoint. It integrates all of the important design factors associated with facilities planning. It incorporates most of the desired properties with respect to the overall plant operations. At the same time, the framework also summarizes the difficulties and complexities which confront the facility designer. The description of the framework is intended as a general exposition of the fundamental concepts and a direction for future research in facilities planning.

## 13.5 Rapid Prototyping

---

Takeo Nakagawa

### Manufacturing Processes in Parts Production

The rapid progress of CAD technology for the design of machine parts has now made it easy to store three-dimensional shape data on computers. The application of this three-dimensional data has realized NC programming by CAD/CAM, resulting in the remarkable advance of automated production. The increase in highly functional machine parts and advanced designs has led to the design of more and more complicated surfaces using CAD. To reduce the lead time and costs for the development of new industrial products, “rapid prototyping” has been recognized as a unique, layered manufacturing technique for making prototypes.

With this rapid prototyping, shapes of machine parts are created by building up layers and layers of materials, unlike the material-removal technique which shapes by gradual machining using a cutting tool. In this sense, rapid prototyping resembles the joining technique of small particles or thin layers. Various different types of rapid prototyping methods have been born over the last couple of years. A common feature of these methods is that parts are directly shaped fully automatically according to CAD data. Specifically, in all of these methods, the three-dimensional CAD data is taken as composed of thin layers of two-dimensional data. The thin layers are formed using the two-dimensional data and built up to form an actual three-dimensional solid product. With the nature of the processing steps, this rapid prototyping technique is called *layered manufacturing*. As the method can also be used in other applications than prototyping, it is also referred to as *free-form fabrication*. Because three-dimensional objects can be made from three-dimensional CAD data, this new rapid-prototyping method is also called three-dimensional plotting. At the present time, laser stereolithography is the most widespread rapid-prototyping method.

### Rapid Prototyping by Laser Stereolithography

Laser stereolithography involves the use of a liquid photocurable resin which cures instantaneously when scanned with a laser as a result of polymerization. As shown in [Figure 13.5.1](#), the laser is scanned over this resin repeatedly to form thin layers of cured resin, which eventually build up to form a three-dimensional solid product. Specifically, the process involves first slicing a model based on three-dimensional CAD data stored on computer horizontally into equal thickness. Based on this slice data, the laser scans the thin liquid resin layer to form the first solid layer. Liquid resin is then poured over this cured layer of resin and again scanned by laser to form the next layer according to the next slice data. To ensure that the liquid resin on the cured resin is even, its surface is often swept by a blade. So, by repeating this process and forming layer over layer of cured resin, a solid object is formed.

Although the surface accuracy problems are resolved by making each layer extremely thin, a small amount of roughness of the surface eventually remains and subsequent polishing is often performed to achieve a smooth finish. For shapes which cannot be formed by building the layers upward, the resin is cured on a support. This support is also made of the same photocurable resin and is removed after the product has been formed. For some types of resins which do not cure completely with a laser alone, the whole product is cured by exposure to an ultraviolet lamp after it has been formed.

The photocurable resin is composed of photopolymerizing oligomer, reactive diluent, and photoinitiator. When a laser is irradiated onto this resin, the monomer undergoes a series of reactions to form a solid polymer which has a three-dimensional network structure. The resins used for laser stereolithography are the radical polymerization type, the cation polymerization type, or the hybrid type, which is a combination of the first two types. The curing properties and mechanical properties of the cured resin are important, because these affect the applications of the cured product formed by laser stereolithography. These resins are prepared minutely by adjusting the mixture rate of the resin components and the additives to suit laser stereolithography.

**FIGURE 13.5.1** Principle of photocurable resin process.

In most cases, the He-Cd laser with 325-nm wavelength or Ar laser with 364-nm wavelength is used as the light source. Higher-power lasers like Ar perform higher-speed beam scanning, resulting in the increase of modeling speed. As shown in [Figure 13.5.2](#), these lasers scan at very high speed in the same way as the laser printer by rotating galvanomirrors. In some special machines, the laser beam is exposed from the bottom as shown in [Figure 13.5.3](#) by an XY plotter.

**FIGURE 13.5.2** Scanning system of UV laser beam.

Laser stereolithography requires three-dimensional CAD data composed of surface or solid data in order to create solid models. Many types of CAD systems are now available on the market, and most of the CAD data they provide can be transmitted to laser stereolithography systems. At the same time, the laser stereolithography system is equipped with a scanning program, support and reinforcing rib design software, magnification/contraction functions, functions to determine the scanning and operating conditions, and simulation functions. [Figure 13.5.4](#) shows a software flowchart in laser stereolithography.

The following shows the advantages of rapid-prototyping over material-removing processes such as machining.

**FIGURE 13.5.3** Laser beam radiation from below (Denken).

1. Deep holes and structures with complicated internal shapes which cannot be machined simply by cutting tools can be formed in a single process. Moreover, one rapid-prototyping machine is usually capable of fabricating any type of shape.
2. Rapid prototyping requires no complicated control programs such as tool path and repositioning of the workpiece. With the three-dimensional CAD data, there is no need for special knowledge of the cutting process, and operations from data input to actual fabrication are simple and short.
3. The rapid-prototyping systems produce no machining wastes. Because they do not vibrate and are silent, they can be used in offices like OA business machines. They can also be operated fully automatically even at night since there is no need for the management of tooling.

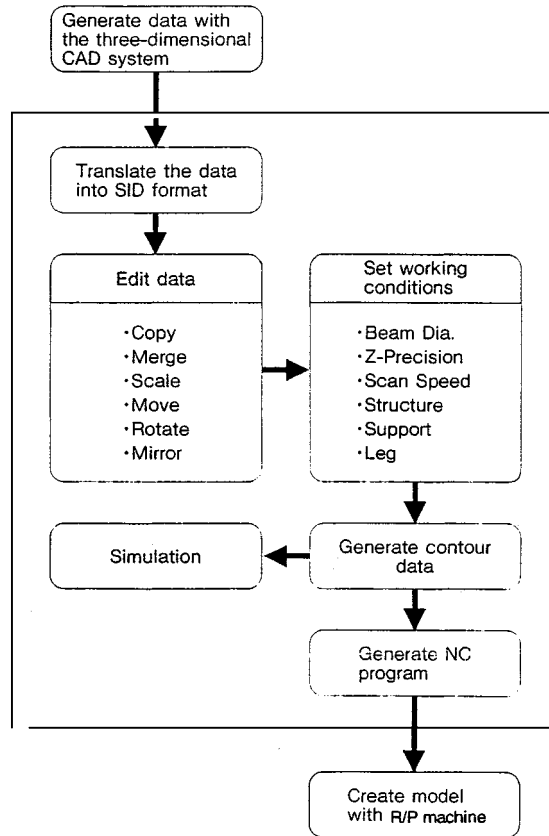

The major shortcomings of laser stereolithography are that only photocurable resins can be used and the material strength of these materials is slightly worse than the common polymer. In addition, metal products cannot be manufactured directly by laser stereolithography.

## Other Rapid-Prototyping Methods

The laser stereolithography method was developed in an early stage and is currently applied extensively. Besides laser stereolithography, many different types of new rapid-prototyping methods have also emerged. As shown in [Figure 13.5.5](#), rapid prototyping can broadly be classified into photopolymer, powder sintering, ink jetting, fused deposition, and sheet cutting. [Figure 13.5.6](#) shows the history of these rapid prototyping systems. Most of the methods were developed in the U.S., but the photopolymer process and sheet lamination were first proposed in Japan.

Another photopolymer process is the mask pattern-curing method shown in [Figure 13.5.7](#). Similar to the photocopying process, a master pattern based on slice data is created, this pattern on the glass sheet is placed over a photocurable resin layer, and this layer is exposed to ultraviolet light. Although the machine is large, the exposing speed is faster than the above-mentioned laser beam method, and the thickness of the product is very precise because each surface formed is cut by milling to obtain precise thin layers.

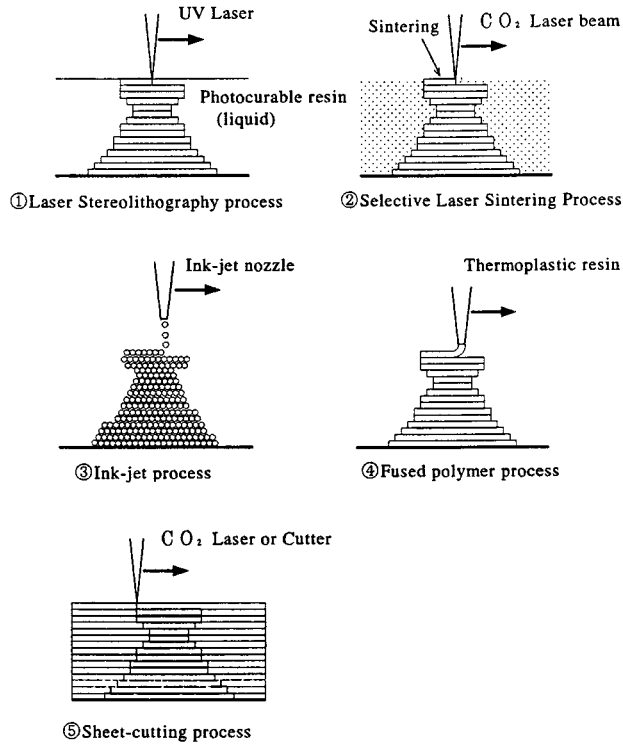

**FIGURE 13.5.4** Software for R/P system (CMET).

Three-dimensional objects can also be formed by powder sintering. In the process shown in [Figure 13.5.8](#), powder is used instead of liquid photocurable resin. The powder is evened out using a roller, a CO<sub>2</sub> laser is beamed, and the powder is bonded by heat fusion. In this case, powder is heated up beforehand to the temperature just below the melting point in the antioxidation environment using N<sub>2</sub> gas. It is possible to create high-density polymer solid models as well as porous models.

Porous polycarbonate models are quite suitable for the investment casting model. With this method, metal and ceramic powders can also be used. Metal and ceramic powders used are coated by resin and each metal or ceramic powder is bonded by the coated resin. Sintered porous ceramic molds can be used for casting molds. Powder binding can be performed by spraying binding material on the loose powder layer through the ink jet nozzle as shown in [Figure 13.5.9](#). This is also used for making the sand mold for casting. When wax or resin is sprayed from the jet nozzle, wax or resin models can be fabricated as shown in [Figure 13.5.10](#). In this case, the surface of the sprayed thin layer should be machined smoothly and flatly in order to obtain vertical accuracy.

[Figure 13.5.11](#) shows the fused deposition method. In this method, a fine nozzle deposits a layer of resin or wax. Wax is normally used to form lost wax models. Fused deposition systems, in which material is supplied by the pellet or wire, enable materials to be formed very similarly to general injection mold materials like ABS and nylon. One of the two nozzles is used for making the support, where the support material is usually wax with lower melting points.

[Figure 13.5.12](#) shows two methods which cut thin sheets according to slice data and laminate them to form three-dimensional objects. One method uses a laser to cut sheets applied with adhesive which are then laminated by hot toll pressing, while the other uses a knife to cut the sheets. In the latter case,

**FIGURE 13.5.5** Schematic of various layer-additive fabrication processes.

adhesive is applied to sheets of paper according to the desired shape by spraying the toner using a dry Xerox-type copy machine. Due to the use of paper in these sheet lamination methods, the model formed should be immediately coated to prevent the absorption of moisture. Although there is a limit to the shapes that can be made, the method is nevertheless used for making wood models for casting, because it is inexpensive and enables large-sized models to be made and the model material is similar to wood.

The common feature of all of these methods is that slice data is obtained from three-dimensional CAD data and this slice data is used to laminate thin layers of material, which means that the same software can be used for all of these methods. Another feature is that all rapid-prototyping machines use the modified printing technology.

While many of these rapid-prototyping machines tend to be costly, inexpensive models are also now available. Machine cost reduction has been achieved by proper utilization of key parts which are used for the printer. New and improved methods should continue to be developed with the introduction of printing technology.

### Application of Rapid Prototyping

Figure 13.5.13 shows the applications of three-dimensional models made by rapid prototyping. They are mainly intended for verifying CAD data, checking the designs, functional checks of prototypes, wax models for investment casting, master models for die and model making, mold making for prototype manufacturing, casting models, and medical use CT and MRI data. Although dimensional accuracy was given little importance in the verification stage of CAD data and design, high dimensional accuracy is now demanded of the functional check of prototypes. Because photocurable resins contract in the solidification process, slight distortions are generated in the fabricated product. Among the various rapid-prototyping machines, the photocurable resin process is most suitable for making very complicated shapes and obtaining the highest accuracy.

Even in laser stereolithography, accuracy has improved to a considerable extent with the improvement of the resin and scanning method and the accumulation of know-how for positioning the reinforcing rib. It should also be possible to attain the same accuracy as injection molds by measuring formed products, correcting the data, or predicting errors.

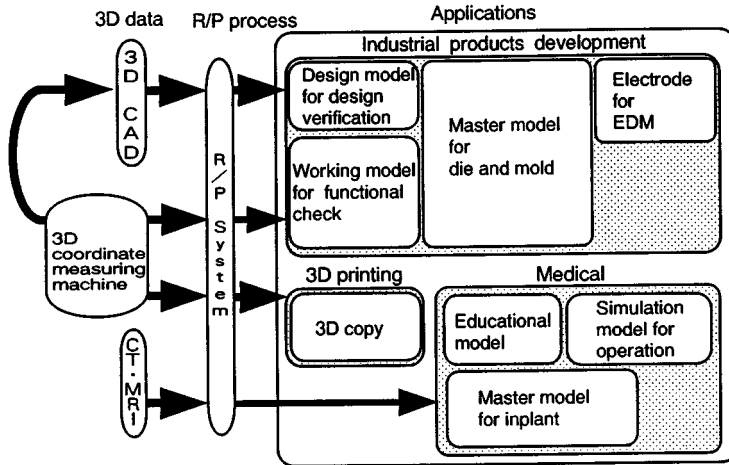

FIGURE 13.5.13 Application of rapid prototyping (source: CMET).

In general, photocurable resins are generally weak and brittle as compared with conventional polymer parts produced by injection molds. Urethane resin which is usually used for vacuum casting with a silicon rubber mold reversely copied from a rapid-prototyping model also lacks the required strength. In order to carry out the functional check of the prototypes created, other processes which can use normal thermoplastic should be used.

Figure 13.5.14 shows an intake manifold for car engines made by laser stereolithography. This serves as a test model for checking fluid performance of air. For such purposes, current photocurable resins available prove relatively satisfactory.

FIGURE 13.5.14 Sample for fluid dynamic analysis.

Although the powder sintering process can apply some metals, there is no suitable rapid-prototyping technique which can directly form products from metal materials at the moment. Research activities are underway to study the feasibility of producing molds from metal materials directly using a three-dimensional printing technique. In a general application, the lost wax models are first made by rapid prototyping and then used for creating metal prototypes by investment casting.

Rapid prototyping is still a relatively new technology, and therefore there are considerable opportunities for technical improvements.

## General Rapid Prototyping in Production

For rapid prototyping to be carried out, three-dimensional CAD data must be available. Creating the CAD data takes far more time than creating the three-dimensional models based on the CAD data. By realizing efficient concurrent engineering, rapid prototyping will no doubt become a very important tool. In general, many other types of production systems can be included in the list of systems currently termed *general rapid prototyping* (casting and machining, etc.).

### Use of Three-Dimensional CAD Data

Casting methods which are able to produce green sand molds satisfy the conditions of rapid prototyping. Expendable pattern casting is also suitable for rapid manufacturing. In this case, a three-dimensional polystyrene foam model is made by machining or binding. Most of the industrial products around us are produced with dies and molds. Because they are expensive to manufacture, dies and molds are unsuitable for making prototypes and for small-lot production. This may be a reason why rapid prototyping was developed; however, some prototype production methods do involve the use of dies and molds. Flexible prototype production has been carried out in sheet metal forming with the use of the turret punch press, laser beam cutting machine, and NC press brake. Producing dies and molds rapidly and manufacturing using such dies and molds also fit into the category of general rapid prototyping in the broad sense. Examples include what is known as the low-cost blanking dies using steel rule, deep drawing die made of zinc alloy and bismuth alloy.

Among the many general rapid-prototyping systems that exist, those newly developed rapid-prototyping methods discussed are gradually becoming methods for creating complicated products accurately with the use of three-dimensional CAD data. In terms of the total cost, applications of these new methods are still limited, but the spread of three-dimensional CAD data and technological progress of rapid prototyping should make them one of the common manufacturing techniques in the near future.

## 13.6 Underlying Paradigms in Manufacturing Systems and Enterprise Management for the 21st Century

### Quality Systems

*H. E. Cook*

#### Introduction

Quality engineering has been described as the process of minimizing the sum of the total costs and the functional losses of manufactured products. Total costs include variable costs, investment, maintenance/repair costs, environmental losses, and costs of disposal or recycling. Functional losses arise from deviations from ideal performance. A subset of total quality management, quality engineering, focuses on parameter and tolerance design after the target specifications for the product have been developed as part of system design.

In contrast to quality engineering, total quality management embraces the entire product realization process. Its objective should be to maximize the net value of the product to society which includes buyer, seller, and the rest of society. Product value is determined solely by the customer and can be set equal to the maximum amount the customer would be willing to pay for the product. For a product to be purchased, its price must be less than its perceived value to the customer at the time of purchase. Consumer surplus is the difference between value and price.

The true value of a product is formed by the customer after assessing the product's performance over the complete time period that he or she used it. Functional quality loss is also known as the cost of inferior quality which is equal to the loss of value incurred by a product as a result of its attributes being off their ideal specification points (Figure 13.6.1). When manufacturing costs are added to value, the resulting sum (equal to total quality less environmental losses) is maximized when the attribute is off its ideal specification because of the impossibly high costs required to make a product perfect.

**FIGURE 13.6.1** The relation of product value to the cost of inferior quality.

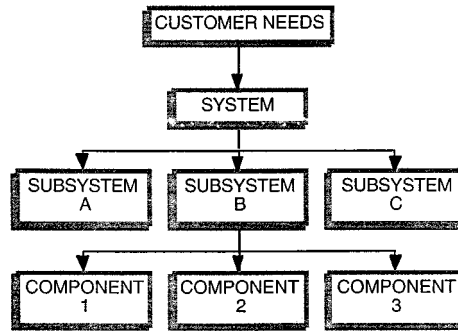

#### Requirements Flow

The systems viewpoint, as expressed by the flow of requirements shown in Figure 13.6.2, is helpful in considering the full ramifications of total quality management. Every system can be divided into subsystems and every system is but a subsystem of a larger system. Each task receives input requirements from its customer (either internal or external) and sends output requirements to its suppliers.

#### Task Objectives

A major objective of the system task is to assess customer needs, to translate those needs into a complete set of system-level specifications for the product, and to send a key (but partial) set of subsystem requirements to those responsible for the subsystem tasks. The system specifications and subsystem requirements developed by the system task should be such that (1) customers will want to purchase the product in a competitive marketplace and, with use, find that the product meets or exceeds their

**FIGURE 13.6.2** Flow of requirements from customer through enterprise.

expectations, (2) the product will meet the profitability objectives of the enterprise, and (3) all environmental rules and regulations are met. The system task also has the responsibility of resolving conflicts which arise between subsystem tasks.

The subsystem task receives the key requirements from its internal customer and translates these into a complete set of subsystem requirements and sends a key (but partial) set of component requirements to those responsible for the component tasks. In turn, those responsible for each component task translate the requirements received into a complete set of component requirements and a partial (but key) set of raw material requirements. Requirements set at each level include controls on variable costs, investment, performance, reliability, durability, service, disposal, environmental quality, package, assembly, and timing for both production and prototype parts. Synchronization is very important to total quality management as parts should be received exactly when needed with minimal inventory.

### Parts Flow

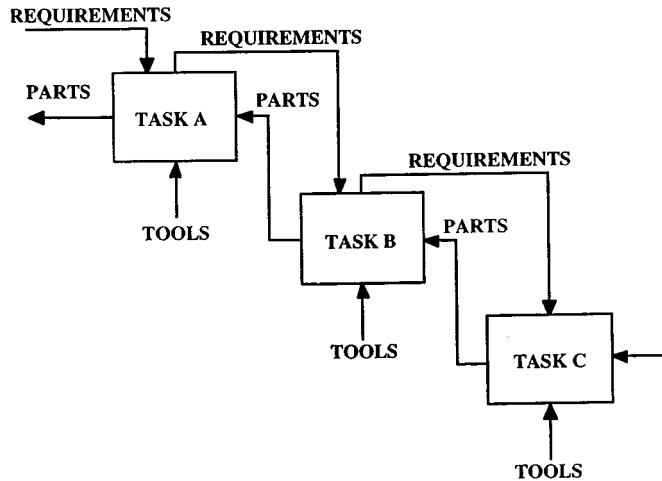

The response to the requirements flow is a parts flow in the opposite direction that begins with the conversion of raw materials into components. This is followed by the assembly of components into subsystems which are shipped to the system task for final assembly. The process is completed by shipping the finished product to the customer. Thus, each task shown in [Figure 13.6.1](#) has both a planning or design function as well as other functions including manufacturing, assembly, purchasing, marketing, service, accounting, and finance. The actions taken to meet customer needs should be traceable as the requirements flow through the enterprise. With the systems viewpoint, all parameters are measured or computed at the full system level including value, costs, and investment.

### Task Management

Within each task shown in [Figure 13.6.2](#) are subtasks. The combined flow of requirements and parts between several subtasks is shown in [Figure 13.6.3](#) using a modified IDEF representation. Requirements are shown as controls which flow from left to right, and parts, in response, are shown as flowing from right to left.

Each task is accomplished by exercising its authority, responsibility, and capability. Authority to set requirements on parts should rest fully and undiluted with the task receiving the parts. The task which ships the parts should possess the full authority, responsibility, and capability to manufacture the parts for its customer. Before sourcing of parts, demonstration of capability by the manufacturer is a vital element of sound quality engineering. Capability is ultimately determined by the set of tools which the task has at its disposal and includes the skills and experience of the people as well as the hardware and software used by them.

Because a broad range of skills is needed, the required expertise is generated by forming a team to carry out the task. Quality tools used by the teams include structured methodologies such as Taguchi methods (design of experiments), quality function deployment, failure mode effects and criticality

**FIGURE 13.6.3** The flow of requirements and parts in a modified IDEF0 (function model) representation.

analysis, statistical process control, cost analysis, and value analysis. It is highly recommended that final authority and responsibility for each task rest with one person.

### Fundamental and Bottom-Line Metrics

A variety of parameters can be used to measure the progress of quality improvements. These include things such as the degree of customer satisfaction expressed for the product, the frequency of repair, and the variance found in product dimensions and performance levels that directly impact value to the customer. Repair and operating costs borne by the customer subtract from value if they are greater than what was anticipated by the customer. Likewise, resale price subtracts from value if it is below what the customer expected. Performance degradation of the product over its lifetime of use subtracts from its value. Noise and atmospheric pollution caused by the manufacture and use of the product subtract from the net value of the product to society. The costs to manufacture and develop the product subtract from the net value received by the manufacturer. Moreover, products which are not improved in value and reduced in costs at the pace of competing products will likely be eliminated from the market in time.

These metrics can be grouped into one of three categories — value, cost, and the pace of innovation. They represent the fundamental metrics for the product because they determine what the bottom-line metrics of profitability and market share will be. Management of the fundamental metrics is the management of total quality and, likewise, the management of the total enterprise. The level of sustained profitability is the best measure of how well total quality is being managed in competitive markets.

## Collaborative Manufacturing

*James J. Solberg*

### Introduction

The world of manufacturing is undergoing rapid change in almost every aspect. It has become something of a cliché to speak of paradigm shifts, but there is no doubt that many assumptions, beliefs, and practices of the past are being seriously questioned. Meanwhile, the daily struggle of manufacturing enterprises to cope with the ordinary problems of producing products and satisfying customers goes on. In ecological terms, manufacturing companies are faced with a competitive struggle for survival (as always), augmented with the additional challenge of a changing climate. It is not surprising that many people are confused about what is happening and what to do about it.

### What Is Collaborative Manufacturing (CM)?

CM is a very broad arena which incorporates many other topical themes of the day, including team design, computer-supported collaborative work, agile manufacturing, enterprise integration, virtual enterprises, high-performance distributed computing, concurrent engineering, computer-integrated manufacturing, virtual reality, global sourcing, and business process reengineering. In general, CM is defined by the following attributes:

- Integrated product and process development, including customers and suppliers;
- Flexible manufacturing distributed over networks of cooperating facilities;
- Teamwork among geographically and organizationally distributed units;
- High-technology support for the collaboration, including high-speed information networks and integration methodology;
- Multidisciplines and multiple objectives.

What is the payoff for CM? Companies that can engage effectively in CM will have the potential for

- Better market opportunities;
- A wider range of design and processing options over which to optimize;
- Fewer and looser constraints restricting their capabilities;
- Lower investment costs;
- Better utilization of resources;
- Faster response to changes.

Obviously, we are still a long way from being able to do what was described in our scenario. However, many of the pieces are already available, and many of the enabling technologies are rapidly coming into commercial use. The high-speed networks (well beyond current Internet speeds) are being developed and are certain to become both cost-effective and ubiquitous within a few years. The needed software developments, such as agent programming languages and interoperability standards, are progressing nicely. Nevertheless, an enormous agenda for needed research can be derived from unmet needs, particularly in areas that directly relate traditional manufacturing to information technology. Bridging these two research communities will not be easy, but the effort will offer great rewards to those who succeed.

### Who Is Doing CM?

A great deal of the current work in CM and related themes is best accessed through the Internet. Understandably, the most active researchers in these fields are “Internet aware” and use it for both gathering and distributing their knowledge. Consequently, the best way to survey recent work is to browse the net, following links to associated sites. Unfortunately, the medium is so dynamic that material can appear or disappear at any time. A few of the better home pages are given here as starting points. Search engines can pick up more current connections.

## Electronic Data Interchange

*Chris Wang*

### Introduction

Electronic data interchange (EDI) is a method to exchange business information between computer systems. In a traditional purchasing environment, buyers, when placing computer-generated orders, will mail them to suppliers, and it could take days before the suppliers receive them and then rekey the orders into their computer system. Using EDI, the buyer's computer system can generate an EDI standard order transaction and transmit it directly to the supplier's inventory system for material pickup. It happens instantly. The benefit of EDI is quite obvious in this case as it reduces material lead time dramatically. Consequently, the objectives of EDI implementation should not be limited to just reducing paperwork and clerical work; instead, it should be used as a methodology to streamline company processes and become competitive in the marketplace.

### EDI Elements

EDI consists of the following elements:

- Trading partners — The parties, such as a manufacturer and a supplier, who agree to exchange information.
- Standards — The industry-supplied national, or international formats to which information is converted, allowing disparate computer systems and applications to interchange it. This will be discussed in more detail later.
- Applications — The programs that process business information. For example, an orders application can communicate with an orders entry application of the trading partner.
- Translation — The process of converting business information, usually from a format used by an application, to a standard format, and vice versa.

- **Electronic transmission** — The means by which the information is delivered, such as a public network. Some companies may choose to build their own transmission facilities. For others, VAN (value-added network) seems to be a good choice as companies do not have to invest heavily in communication equipment and personnel to support it. The VAN provider can handle disparate communication hardware and software and provide wide-area network access at a reasonable cost.

### **EDI in Manufacturing**

In the present-day business environment, many companies are turning to just-in-time (JIT) and other techniques to compete as effectively as possible. EDI can make an important contribution to the success of JIT by ensuring that information exchanged between business partners is also just in time.

In traditional manufacturing, material is stored in quantities much larger than required because of faulty components and possible waste in the production process. To solve problems of carrying safety stock and still producing high-quality product, JIT seems to be an effective technology.

JIT systems are designed to pull raw materials and subassemblies through the manufacturing process only when they are needed and exactly when they are needed. Also, with rapidly changing production needs, orders are getting smaller and are issued more frequently. The traditional paperwork environment simply cannot effectively cope with this change. This is why EDI comes in to play a key role to provide fast, accurate information to achieve these JIT goals. In other words, EDI can provide JIT information in manufacturing processes.

- **EDI cuts order delivery and lead time** — The more control points you have in a process, the greater the number of potential problems. EDI eliminates “control points” for the order process. It eliminates the need to mail orders and rekey order information at the receiving end. It reduces the material lead time for production use.
- **Connect applications and processes** — With EDI capability, information, such as scheduling, orders, advance delivery notice, statistical process control data, and material safety data sheets can pass quickly and accurately from the supplier’s computer application to the customer’s computer application, so that arriving material can be put to production use with confidence. This meets one of the important goals of JIT, that is, to turn the supplier’s entire production line into a vast stockroom so a company does not have to maintain a huge warehouse and the working capital tied to excess inventory.
- **Improve relationship with customers and suppliers** — In the supply chain environment, the quicker the chain moves, the better the customers’ needs can be met. With quicker orders, acknowledgments, order changes, and invoices, EDI can satisfy customers’ needs more quickly. Also, the time spent on order tracking and error recovery can now be used in a more productive way and can improve customer/supplier relationships. Companies deeply involved in EDI may see the number of suppliers reduced. This is because through the EDI process, a company can weed out many suppliers who are not efficient and reliable.

### **EDI Standards**

When two organizations exchange business forms electronically, information is encoded and decoded by the computer software of both parties. Therefore, the information must be unambiguous, in order to avoid different interpretations. This relates to the meaning of the terms used, the representation of data used, the codes to be used for data, and the sequence in which data are to be transmitted. All these parameters must be arranged between the two parties on a detailed level.

There are many standard types — it can be based on bilateral agreement, imposed by a dominating party in a certain marketplace, or jointly developed by an industrial group. Some standards have been ratified by international organizations.

The pioneer of EDI standard development was the transportation industry. TDCC (Transportation Data Coordinating Committee) developed sets of standards for transportation mode — air, ocean, motor,

and rail. Later, the U.S. grocery industry developed a set of standards, UCS (Uniform Communication Standard), based on TDCC structure.

The TDCC and UCS are more geared toward the business forms exchanged by shipper/carrier, for example, bill of lading. Not until the American National Standards Institute got involved did a general use standard for all industries start to develop, leading to the birth of ANSI X12 standards.

The ANSI X12 is popular in the U.S. Although ANSI X12 is intended for all industries, different user groups still come up with their own conventions to address their specific needs but remain under the X12 umbrella. To name a few, there are AIAG (Automotive Industry Action Group) for the auto industry, CIDX for the chemical industry, and EIDC for the electronic industry.

In Europe, at approximately the same time period, under the leadership of the United Kingdom, the TDI (Trade Data Interchange) was developed. The TDI syntax and structure are quite different from the ANSI X12. To resolve the incompatibility, the U.N. organization UNJEDI was formed to develop an EDI international standard containing features from both TDI and ANSI X12. The result was EDIFACT (EDI for Administrative, Commerce, and Transport). This is the standard to which the world is trying to convert.

### **EDI Implementation**

Before implementation of EDI, planning is critical to success. First, get all the right people involved in planning and implementation of EDI. Ensure that every employee gets EDI education on how to use EDI as a business tool to manage his or her job. Prepare a strategic plan to get approval and support from top management. Top management should be aware of the significant benefits of EDI and has to appreciate the potential of EDI as a business methodology to improve the bottom line.

As part of a strategic plan, it is crucial to perform an operational evaluation. This evaluation details how the internal departments of the company function. For each paper document under evaluation, information flow is tracked, processing procedures are scrutinized, time is measured, and costs are calculated. This will provide top management with valuable information as important as industry trends and competition information. The operational evaluation provides the company with detailed documentation about how it does business in a paper-based environment. This information then serves as a benchmark against which to measure projected costs and benefits of the EDI model.

Once the strategic plan is in place, available resources must be allocated to the departments that will generate the most benefits for the company. Once EDI is implemented in the company, the next step is to sell it to trading partners to maximize the EDI investment.

### **Summary**

EDI is on a fast growing path. EDI software and communication services are available and not expensive. It will not be too long before EDI becomes mandatory as a business practice. If a company is determined to implement EDI, it should look beyond just connecting two computer systems. To achieve the best return on the EDI investment, one should try to use EDI to improve the existing processes within the organization and the relationship with customers and suppliers.

## 14.1 Introduction

---

The word “robot” was introduced by the Czech playwright Karel Čapek in his 1920 play *Rossum’s Universal Robots*. The word “robota” in Czech means simply “work.” In spite of such practical beginnings, science fiction writers and early Hollywood movies have given us a romantic notion of robots. Thus, in the 1960s robots held out great promises for miraculously revolutionizing industry overnight. In fact, many of the more far-fetched expectations from robots have failed to materialize. For instance, in underwater assembly and oil mining, teleoperated robots are very difficult to manipulate and have largely been replaced or augmented by “smart” quick-fit couplings that simplify the assembly task. However, through good design practices and painstaking attention to detail, engineers have succeeded in applying robotic systems to a wide variety of industrial and manufacturing situations where the environment is structured or predictable. Today, through developments in computers and artificial intelligence techniques and often motivated by the space program, we are on the verge of another breakthrough in robotics that will afford some levels of autonomy in unstructured environments.

On a practical level, robots are distinguished from other electromechanical motion equipment by their dexterous manipulation capability in that robots can work, position, and move tools and other objects with far greater dexterity than other machines found in the factory. Process robot systems are functional components with grippers, end effectors, sensors, and process equipment organized to perform a controlled sequence of tasks to execute a process — they require sophisticated control systems.

The first successful commercial implementation of process robotics was in the U.S. automobile industry. The word “automation” was coined in the 1940s at Ford Motor Company, as a contraction of “automatic motivation.” By 1985 thousands of spot welding, machine loading, and material handling applications were working reliably. It is no longer possible to mass produce automobiles while meeting currently accepted quality and cost levels without using robots. By the beginning of 1995 there were over 25,000 robots in use in the U.S. automobile industry. More are applied to spot welding than any other process. For all applications and industries, the world’s stock of robots is expected to exceed 1,000,000 units by 1999.

The single most important factor in robot technology development to date has been the use of microprocessor-based control. By 1975 microprocessor controllers for robots made programming and executing coordinated motion of complex multiple degrees-of-freedom (DOF) robots practical and reliable. The robot industry experienced rapid growth and humans were replaced in several manufacturing processes requiring tool and/or workpiece manipulation. As a result the immediate and cumulative dangers of exposure of workers to manipulation-related hazards once accepted as necessary costs have been removed.

A distinguishing feature of robotics is its multidisciplinary nature — to successfully design robotic systems one must have a grasp of electrical, mechanical, industrial, and computer engineering, as well as economics and business practices. The purpose of this chapter is to provide a background in all these areas so that design for robotic applications may be confronted from a position of insight and confidence. The material covered here falls into two broad areas: function and analysis of the single robot, and design and analysis of robot-based systems and workcells.

Section 14.2 presents the available configurations of commercial robot manipulators, with Section 14.3 providing a follow-on in mathematical terms of basic robot geometric issues. The next four sections provide particulars in end-effectors and tooling, sensors and actuators, robot programming languages, and dynamics and real-time control. Section 14.8 deals with planning and intelligent control. The next three sections cover the design of robotic systems for manufacturing and material handling. Specifically, Section 14.9 covers workcell layout and part feeding, Section 14.10 covers product design and economic analysis, and Section 14.11 deals with manufacturing and industrial processes. The final section deals with some special classes of robots including mobile robots, lightweight flexible arms, and the versatile parallel-link arms including the Stewart platform.

## 14.2 Commercial Robot Manipulators

---

*John M. Fitzgerald*

In the most active segments of the robot market, some end-users now buy robots in such large quantities (occasionally a single customer will order hundreds of robots at a time) that market prices are determined primarily by configuration and size category, not by brand. The robot has in this way become like an economic commodity. In just 30 years, the core industrial robotics industry has reached an important level of maturity, which is evidenced by consolidation and recent growth of robot companies. Robots are highly reliable, dependable, and technologically advanced factory equipment. There is a sound body of practical knowledge derived from a large and successful installed base. A strong foundation of theoretical robotics engineering knowledge promises to support continued technical growth.

The majority of the world's robots are supplied by established stable companies using well-established off-the-shelf component technologies. All commercial industrial robots have two physically separate basic elements: the manipulator arm and the controller. The basic architecture of all commercial robots is fundamentally the same. Among the major suppliers the vast majority of industrial robots uses digital servo-controlled electrical motor drives. All are serial link kinematic machines with no more than six axes (degrees of freedom). All are supplied with a proprietary controller. Virtually all robot applications require significant effort of trained skilled engineers and technicians to design and implement them. What makes each robot unique is how the components are put together to achieve performance that yields a competitive product. Clever design refinements compete for applications by pushing existing performance envelopes, or sometimes creating new ones. The most important considerations in the application of an industrial robot center on two issues: Manipulation and Integration.

### Commercial Robot Manipulators

#### Manipulator Performance Characteristics

The combined effects of kinematic structure, axis drive mechanism design, and real-time motion control determine the major manipulation performance characteristics: reach and dexterity, payload, quickness, and precision. Caution must be used when making decisions and comparisons based on manufacturers' published performance specifications because the methods for measuring and reporting them are not standardized across the industry. Published performance specifications provide a reasonable comparison of robots of similar kinematic configuration and size, but more detailed analysis and testing will insure that a particular robot model can reach all of the poses and make all of the moves with the required payload and precision for a specific application.

*Reach* is characterized by measuring the extents of the space described by the robot motion and *dexterity* by the angular displacement of the individual joints. Horizontal reach, measured radially out from the center of rotation of the base axis to the furthest point of reach in the horizontal plane, is usually specified in robot technical descriptions. For Cartesian robots the range of motion of the first three axes describes the reachable workspace. Some robots will have unusable spaces such as dead zones, singular poses, and wrist-wrap poses inside of the boundaries of their reach. Usually motion test, simulations, or other analysis are used to verify reach and dexterity for each application.

*Payload weight* is specified by the manufacturer for all industrial robots. Some manufacturers also specify inertial loading for rotational wrist axes. It is common for the payload to be given for extreme velocity and reach conditions. Load limits should be verified for each application, since many robots can lift and move larger-than-specified loads if reach and speed are reduced. Weight and inertia of all tooling, workpieces, cables, and hoses must be included as part of the payload.

*Quickness* is critical in determining throughput but difficult to determine from published robot specifications. Most manufacturers will specify a maximum speed of either individual joints or for a specific kinematic tool point. Maximum speed ratings can give some indication of the robot's quickness but may be more confusing and misleading than useful. Average speed in a working cycle is the quickness

characteristic of interest. Some manufacturers give cycle times for well-described motion cycles. These motion profiles give a much better representation of quickness. Most robot manufacturers address the issue by conducting application-specific feasibility tests for customer applications.

Precision is usually characterized by measuring repeatability. Virtually all robot manufacturers specify static position repeatability. Usually, tool point repeatability is given, but occasionally repeatability will be quoted for each individual axis. *Accuracy* is rarely specified, but it is likely to be at least four times larger than repeatability. Dynamic precision, or the repeatability and accuracy in tracking position, velocity, and acceleration on a continuous path, is not usually specified.

### Common Kinematic Configurations

All common commercial industrial robots are serial link manipulators with no more than six kinematically coupled axes of motion. By convention, the axes of motion are numbered in sequence as they are encountered from the base on out to the wrist. The first three axes account for the spatial positioning motion of the robot; their configuration determines the shape of the space through which the robot can be positioned. Any subsequent axes in the kinematic chain provide rotational motions to orient the end of the robot arm and are referred to as wrist axes. There are, in principle, two primary types of motion that a *robot axis* can produce in its driven link: either *revolute* or *prismatic*. It is often useful to classify robots according to the orientation and type of their first three axes. There are four very common commercial robot configurations: Articulated, Type 1 *SCARA*, Type 2 *SCARA*, and Cartesian. Two other configurations, Cylindrical and Spherical, are now much less common.

*Articulated Arms.* The variety of commercial articulated arms, most of which have six axes, is very large. All of these robots' axes are revolute. The second and third axes are parallel and work together to produce motion in a vertical plane. The first axis in the base is vertical and revolves the arm sweeping out a large work volume. The need for improved reach, quickness, and payload have continually motivated refinements and improvements of articulated arm designs for decades. Many different types of drive mechanisms have been devised to allow wrist and forearm drive motors and gearboxes to be mounted close in to the first and second axis rotation to minimize the extended mass of the arm. Arm structural designs have been refined to maximize stiffness and strength while reducing weight and inertia. Special designs have been developed to match the performance requirements of nearly all industrial applications and processes. The workspace efficiency of well-designed articulated arms, which is the degree of quick dexterous reach with respect to arm size, is unsurpassed by other arm configurations when five or more degrees of freedom are needed. Some have wide ranges of angular displacement for both the second and third axis, expanding the amount of overhead workspace and allowing the arm to reach behind itself without making a 180° base rotation. Some can be inverted and mounted overhead on moving gantries for transportation over large work areas. A major limiting factor in articulated arm performance is that the second axis has to work to lift both the subsequent arm structure and payload. Springs, pneumatic struts, and counterweights are often used to extend useful reach. Historically, articulated arms have not been capable of achieving accuracy as well as other arm configurations. All axes have joint angle position errors which are multiplied by link radius and accumulated for the entire arm. However, new articulated arm designs continue to demonstrate improved repeatability, and with practical calibration methods they can yield accuracy within two to three times the repeatability. An example of extreme precision in articulated arms is the Staubli Unimation RX arm (see [Figure 14.2.1](#)).

*Type I SCARA.* The Type I *SCARA* (selectively compliant assembly robot arm) arm uses two parallel revolute joints to produce motion in the horizontal plane. The arm structure is weight-bearing but the first and second axes do no lifting. The third axis of the Type 1 *SCARA* provides work volume by adding a vertical or Z axis. A fourth revolute axis will add rotation about the Z axis to control orientation in the horizontal plane. This type of robot is rarely found with more than four axes. The Type 1 *SCARA* is used extensively in the assembly of electronic components and devices, and it is used broadly for the assembly of small- to medium-sized mechanical assemblies. Competition for robot sales in high speed electronics assembly has driven designers to optimize for quickness and precision of motion. A

well-known optimal SCARA design is the AdeptOne robot shown in Figure 14.2.2a. It can move a 20-lb payload from point “A” up 1 in. over 12 in. and down 1 in. to point “B” and return through the same path back to point “A” in less than 0.8 sec (see Figure 14.2.2).

(a)

**FIGURE 14.2.2** Type 1 SCARA arms (courtesy of Adept Technologies, Inc.). (a) High precision, high speed mid-sized SCARA; (b) table top SCARA used for small assemblies.

*Type II SCARA.* The Type 2 SCARA, also a four-axis configuration, differs from Type 1 in that the first axis is a long, vertical, prismatic Z stroke which lifts the two parallel revolute axes and their links. For quickly moving heavier loads (over approximately 75 lb) over longer distances (over about 3 ft), the Type 2 SCARA configuration is more efficient than the Type 1. The trade-off of weight vs. inertia vs. quickness favors placement of the massive vertical lift mechanism at the base. This configuration is well suited to large mechanical assembly and is most frequently applied to palletizing, packaging, and other heavy material handling applications (see Figure 14.2.3).

*Cartesian Coordinate Robots.* Cartesian coordinate robots use orthogonal prismatic axes, usually referred to as X, Y, and Z, to translate their end-effector or payload through their rectangular workspace. One, two, or three revolute wrist axes may be added for orientation. Commercial robot companies supply several types of Cartesian coordinate robots with workspace sizes ranging from a few cubic inches to tens of thousands of cubic feet, and payloads ranging to several hundred pounds. Gantry robots are the most common Cartesian style. They have an elevated bridge structure which translates in one horizontal direction on a pair of runway bearings (usually referred to as the X direction), and a carriage which

(b)

**FIGURE 14.2.2** continued

moves along the bridge in the horizontal “Y” direction also usually on linear bearings. The third orthogonal axis, which moves in the Z direction, is suspended from the carriage. More than one robot can be operated on a gantry structure by using multiple bridges and carriages. Gantry robots are usually supplied as semicustom designs in size ranges rather than set sizes. Gantry robots have the unique capacity for huge accurate work spaces through the use of rigid structures, precision drives, and work-space calibration. They are well suited to material handling applications where large areas and/or large loads must be serviced. As process robots they are particularly useful in applications such as arc welding, waterjet cutting, and inspection of large, complex, precision parts.

Modular Cartesian robots are also commonly available from several commercial sources. Each module is a self-contained completely functional single axis actuator. Standard linear axis modules which contain all the drive and feedback mechanisms in one complete structural/functional element are coupled to perform coordinated three-axis motion. These modular Cartesian robots have work volumes usually on the order of 10 to 30 in. in X and Y with shorter Z strokes, and payloads under 40 lb. They are typically used in many electronic and small mechanical assembly applications where lower performance than Type 1 SCARA robots is suitable (see [Figure 14.2.4](#)).

*Spherical and Cylindrical Coordinate Robots.* The first two axes of the spherical coordinate robot are revolute and orthogonal to one another, and the third axis provides prismatic radial extension. The result is a natural spherical coordinate system and a work volume that is spherical. The first axis of cylindrical coordinate robots is a revolute base rotation. The second and third are prismatic, resulting in a natural cylindrical motion.

**FIGURE 14.2.3** Type 2 SCARA (courtesy of Adept Technologies, Inc.).

Commercial models of spherical and cylindrical robots were originally very common and popular in machine tending and material handling applications. Hundreds are still in use but now there are only a few commercially available models. The Unimate model 2000, a hydraulic-powered spherical coordinate robot, was at one time the most popular robot model in the world. Several models of cylindrical coordinate robots were also available, including a standard model with the largest payload of any robot, the Prab model FC, with a payload of over 600 kg. The decline in use of these two configurations is attributed to problems arising from use of the prismatic link for radial extension/retraction motion. A solid boom requires clearance to fully retract. Hydraulic cylinders used for the same function can retract to less than half of their fully extended length. Type 2 SCARA arms and other revolute jointed arms have displaced most of the cylindrical and spherical coordinate robots (see [Figure 14.2.5](#)).

*Basic Performance Specifications.* [Figure 14.2.6](#) summarizes the kinematic configurations just described. [Table 14.2.1](#) is a table of basic performance specifications of selected robot models that illustrates the broad spectrum of manipulator performance available from commercial sources. The information contained in the table has been supplied by the respective robot manufacturers. This is not an endorsement by the author or publisher of the robot brands selected, nor is it a verification or validation of the performance values. For more detailed and specific information on the availability of robots, the reader is advised to contact the Robotic Industries Association, 900 Victors Way, P.O. Box 3724, Ann Arbor, MI 48106, or a robot industry trade association in your country for a listing of commercial robot suppliers and system integrators.

### Drive Types of Commerical Robots

The vast majority of commerical industrial robots uses electric servo motor drives with speed-reducing transmissions. Both AC and DC motors are popular. Some servo hydraulic articulated arm robots are available now for painting applications. It is rare to find robots with servo pneumatic drive axes. All types of mechanical transmissions are used, but the tendency is toward low and zero backlash-type drives. Some robots use direct drive methods to eliminate the amplification of inertia and mechanical backlash associated with other drives. The first axis of the AdeptOne and AdeptThree Type I SCARA

robots is a direct drive motor with the motor stator integrated into the robot base and its armature rotor integral with the first link. Other more common speed-reducing low backlash drive transmissions include toothed belts, roller chains, roller drives, and harmonic drives.

Joint angle position and velocity feedback devices are generally considered an important part of the drive axis. Real-time control performance for tracking position and velocity commands and precision is often affected by the fidelity of feedback. Resolution, signal-to-noise, and innate sampling frequency are important motion control factors ultimately limited by the type of feedback device used.

Given a good robot design, the quality of fabrication and assembly of the drive components must be high to yield good performance. Because of their precision requirements, the drive components are sensitive to manufacturing errors which can readily translate to less than specified manipulator performance.

## **Commercial Robot Controllers**

Commercial robot controllers are specialized multiprocessor computing systems that provide four basic processes allowing integration of the robot into an automation system. These functions which must be factored and weighed for each specific application are Motion Generation, Motion/Process Integration, Human Integration, and Information Integration.

### **Motion Generation**

There are two important controller-related aspects of industrial robot motion generation. One is the extent of manipulation that can be programmed; the other is the ability to execute controlled programmed motion. The unique aspect of each robot system is its real-time kinematic motion control. The details of real-time control are typically not revealed to the user due to safety and proprietary information secrecy reasons. Each robot controller, through its operating system programs, converts digital data into coordinated motion through precise coordination and high speed distribution and communication of the individual axis motion commands which are executed by individual joint controllers. The higher level programming accessed by the end user is a reflection of the sophistication of the real-time controller.

Of greatest importance to the robot user is the motion programming. Each robot manufacturer has its own proprietary programming language. The variety of motion and position command types in a programming language is usually a good indication of the robot's motion generation capability. Program commands which produce complex motion should be available to support the manipulation needs of the application. If palletizing is the application, then simple methods of creating position commands for arrays of positions are essential. If continuous path motion is needed, an associated set of continuous motion commands should be available. The range of motion generation capabilities of commercial industrial robots is wide. Suitability for a particular application can be determined by writing test code.

### **Motion/Process Integration**

Motion/process integration involves methods available to coordinate manipulator motion with process sensor or process controller devices. The most primitive process integration is through discrete digital I/O. For example, an external (to the robot controller) machine controller might send a one-bit signal indicating whether it is ready to be loaded by the robot. The robot control must have the ability to read the signal and to perform logical operations (if then, wait until, do until, etc.) using the signal. At the extreme of process integration, the robot controller can access and operate on large amounts of data in real time during the execution of motion-related processes. For example, in arc welding, sensor data are used to correct tool point positions as the robot is executing a weld path. This requires continuous communication between the welding process sensor and the robot motion generation functions so that there are both a data interface with the controller and motion generation code structure to act on it. Vision-guided high precision pick and place and assembly are major applications in the electronics and semiconductor industries. Experience has shown that the best integrated vision/robot performance has come from running both the robot and the vision system internal to the same computing platform. The

reasons are that data communication is much more efficient due to data bus access, and computing operations are coordinated by one operating system.

### **Human Integration**

Operator integration is critical to the expeditious setup, programming, and maintenance of the robot system. Three controller elements most important for effective human integration are the human *I/O devices*, the information available to the operator in graphic form, and the modes of operation available for human interaction. Position and path teaching effort is dramatically influenced by the type of manual I/O devices available. A teach pendant is needed if the teacher must have access to several vantage points for posing the robot. Some robots have teleoperator-style input devices which allow coordinated manual motion command inputs. These are extremely useful for teaching multiple complex poses. Graphical interfaces, available on some industrial robots, are very effective for conveying information to the operator quickly and efficiently. A graphical interface is most important for applications which require frequent reprogramming and setup changes. Several very useful off-line programming software systems are available from third-party suppliers. These systems use computer models of commercially available robots to simulate path motion and provide rapid programming functions.

### **Information Integration**

Information integration is becoming more important as the trend toward increasing flexibility and agility impacts robotics. Automatic and computer-aided robot task planning and process control functions will require both access to data and the ability to resolve relevant information from CAD systems, process plans and schedules, upstream inspections, and other sources of complex data and information. Many robot controllers now support information integration functions by employing integrated PC interfaces through the communications ports, or in some through direct connections to the robot controller data bus.

## 14.3 Robot Configurations

---

*Ian D. Walker*

### Fundamentals and Design Issues

A robot manipulator is fundamentally a collection of *links* connected to each other by *joints*, typically with an *end effector* (designed to contact the environment in some useful fashion) connected to the mechanism. A typical arrangement is to have the links connected serially by the joints in an open-chain fashion. Each joint provides one or more degree of freedom to the mechanism.

Manipulator designs are typically characterized by the number of independent degrees of freedom in the mechanism, the types of joints providing the degrees of freedom, and the geometry of the links connecting the joints. The degrees of freedom can be revolute (relative rotational motion  $\theta$  between joints) or prismatic (relative linear motion  $d$  between joints). A joint may have more than one degree of freedom. Most industrial robots have a total of six independent degrees of freedom. In addition, most current robots have essentially rigid links (we will focus on rigid-link robots throughout this section).

Robots are also characterized by the type of actuators employed. Typically manipulators have hydraulic or electric actuation. In some cases where high precision is not important, pneumatic actuators are used.

A number of successful manipulator designs have emerged, each with a different arrangement of joints and links. Some “elbow” designs, such as the PUMA robots and the SPAR Remote Manipulator System, have a fairly anthropomorphic structure, with revolute joints arranged into “shoulder,” “elbow,” and “wrist” sections. A mix of revolute and prismatic joints has been adopted in the Stanford Manipulator and the SCARA types of arms. Other arms, such as those produced by IBM, feature prismatic joints for the “shoulder,” with a spherical wrist attached. In this case, the prismatic joints are essentially used as positioning devices, with the wrist used for fine motions.

The above designs have six or fewer degrees of freedom. More recent manipulators, such as those of the Robotics Research Corporation series of arms, feature seven or more degrees of freedom. These arms are termed kinematically redundant, which is a useful feature as we will see later.

Key factors that influence the design of a manipulator are the tractability of its geometric (kinematic) analysis and the size and location of its workspace. The workspace of a manipulator can be defined as the set of points that are reachable by the manipulator (with fixed base). Both shape and total volume are important. Manipulator designs such as the SCARA are useful for manufacturing since they have a simple semicylindrical connected volume for their workspace (Spong and Vidyasagar, 1989), which facilitates workcell design. Elbow manipulators tend to have a wider volume of workspace, however the workspace is often more difficult to characterize. The kinematic design of a manipulator can tailor the workspace to some extent to the operational requirements of the robot.

In addition, if a manipulator can be designed so that it has a simplified kinematic analysis, many planning and control functions will in turn be greatly simplified. For example, robots with spherical wrists tend to have much simpler inverse kinematics than those without this feature. Simplification of the kinematic analysis required for a robot can significantly enhance the real-time motion planning and control performance of the robot system. For the rest of this section, we will concentrate on the kinematics of manipulators.

For the purposes of analysis, a set of *joint variables* (which may contain both revolute and prismatic variables), are augmented into a vector  $q$ , which uniquely defines the geometric state, or configuration of the robot. However, task description for manipulators is most naturally expressed in terms of a different set of *task coordinates*. These can be the position and orientation of the robot end effector, or of a special task frame, and are denoted here by  $Y$ . Thus  $Y$  most naturally represents the performance of a task, and  $q$  most naturally represents the mechanism used to perform the task. Each of the coordinate systems  $q$  and  $Y$  contains information critical to the understanding of the overall status of the manipulator. Much of the kinematic analysis of robots therefore centers on transformations between the various sets of coordinates of interest.

## Manipulator Kinematics

The study of manipulator kinematics at the position (geometric) level separates naturally into two subproblems: (1) finding the position/orientation of the end effector, or task, frame, given the angles and/or displacements of the joints (*Forward Kinematics*); and (2) finding possible angles/displacements of the joints given the position/orientation of the end effector, or task, frame (*Inverse Kinematics*). At the velocity level, the *Manipulator Jacobian* relates joint velocities to end effector velocities and is important in motion planning and for identifying *Singularities*. In the case of *Redundant Manipulators*, the Jacobian is particularly crucial in planning and controlling robot motions. We will explore each of these issues in turn in the following subsections.

### Example 14.3.1

Figure 14.3.1 shows a planar three-degrees-of-freedom manipulator. The first two joints are revolute, and the third is prismatic. The end effector position  $(x, y)$  is expressed with respect to the (fixed) world coordinate frame  $(x_0, y_0)$ , and the orientation of the end effector is defined as the angle of the second link  $\phi$  measured from the  $x_0$  axis as shown. The link length  $l_1$  is constant. The joint variables are given by the angles  $\theta_1$  and  $\theta_2$  and the displacement  $d_3$ , and are defined as shown. The example will be used throughout this section to demonstrate the ideas behind the various kinematic problems of interest.

FIGURE 14.3.1 Planar RRP manipulator.

### Forward (Direct) Kinematics

Since robots typically have sensors at their joints, making available measurements of the joint configurations, and we are interested in performing tasks at the robot end effector, a natural issue is that of determining the end effector position/orientation  $Y$  given a joint configuration  $q$ . This problem is the forward kinematics problem and may be expressed symbolically as

$$Y = f(q) \quad (14.3.1)$$

The forward kinematic problem yields a unique solution for  $Y$  given  $q$ . In some simple cases (such as the example below) the forward kinematics can be derived by inspection. In general, however, the relationship  $f$  can be quite complex. A systematic method for determining the function  $f$  for any manipulator geometry was proposed by Denavit and Hartenberg (Denavit and Hartenberg, 1955).

The Denavit/Hartenberg (or D-H) technique has become the standard method in robotics for describing the forward kinematics of a manipulator. Essentially, by careful placement of a series of coordinate

frames fixed in each link, the D-H technique reduces the forward kinematics problem to that of combining a series of straightforward consecutive link-to-link transformations from the base to the end effector frame. Using this method, the forward kinematics for any manipulator is summarized in a table of parameters (the D-H parameters). A maximum of three nonzero parameters per link are sufficient to uniquely specify the map  $f$ . Lack of space prevents us from detailing the method further. The interested reader is referred to Denavit and Hartenberg (1955) and Spong and Vidyasagar (1989).

To summarize, forward kinematics is an extremely important problem in robotics which is also well understood, and for which there is a standard solution technique

### Example 14.3.2

In our example, we consider the task space to be the position and orientation of the end effector, i.e.,  $Y = [x, y, \phi]^T$  as shown. We choose joint coordinates (one for each degree of freedom) by  $q = [\theta_1, \theta_2, d_3]^T$ . From Figure 14.3.1, with the values as given it may be seen by inspection that

$$x = l_1 \cos(\theta_1) + d_3 \cos(\theta_1 + \theta_2) \quad (14.3.2)$$

$$y = l_1 \sin(\theta_1) + d_3 \sin(\theta_1 + \theta_2) \quad (14.3.3)$$

$$\phi = \theta_1 + \theta_2 \quad (14.3.4)$$

Equations (14.3.2) to (14.3.4) form the forward kinematics for the example robot. Notice that the solution for  $Y = [x, y, \phi]^T$  is unique given  $q = [\theta_1, \theta_2, d_3]^T$ .

### Inverse Kinematics

The *inverse kinematics* problem consists of finding possible joint configurations  $q$  corresponding to a given end effector position/orientation  $Y$ . This transformation is essential for planning joint positions of the manipulator which will result in desired end effector positions (note that task requirements will specify  $Y$ , and a corresponding  $q$  must be planned to perform the task). Conceptually the problem is stated as

$$q = f^{-1}(Y) \quad (14.3.5)$$

In contrast to the forward kinematics problem, the inverse kinematics cannot be solved for arbitrary manipulators by a systematic technique such as the Denavit-Hartenberg method. The relationship (1) does not, in general, invert to a unique solution for  $q$ , and, indeed, for many manipulators, expressions for  $q$  cannot even be found in closed form!

For some important types of manipulator design (particularly those mechanisms featuring spherical wrists), closed-form solutions for the inverse kinematics can be found. However, even in these cases, there are at best multiple solutions for  $q$  (corresponding to “elbow-up,” “elbow-down” possibilities for the arm to achieve the end effector configuration in multiple ways). For some designs, there may be an infinite number of solutions for  $q$  given  $Y$ , such as in the case of kinematically redundant manipulators discussed shortly.

Extensive investigations of manipulator kinematics have been performed for wide classes of robot designs (Bottema and Roth, 1979; Duffy, 1980). A significant body of work has been built up in the area of inverse kinematics. Solution techniques are often determined by the geometry of a given manipulator design. A number of elegant techniques have been developed for special classes of manipulator designs, and the area continues to be the focus of active research. In cases where closed-form solutions cannot be found, a number of iterative numerical techniques have been developed.

**Example 14.3.3**

For our planar manipulator, the inverse kinematics requires the solution for  $q = [\theta_1, \theta_2, d_3]^T$  given  $Y = [x, y, \phi]^T$ . Figure 14.3.2 illustrates the situation, with  $[x, y, \phi]^T$  given as shown. Notice that for the  $Y$  specified in Figure 14.3.2, there are two solutions, corresponding two distinct configurations  $q$ .

**FIGURE 14.3.2** Planar RRP arm inverse kinematics.

The two solutions are sketched in Figure 14.3.2, with the solution for the configuration in bold the focus of the analysis below. The solutions may be found in a number of ways, one of which is outlined here. Consider the triangle formed by the two links of the manipulator and the vector  $(x, y)$  in Figure 14.3.2. We see that the angle  $\epsilon$  can be found as

$$\epsilon = \phi - \tan^{-1}(y/x)$$

Now, using the sine rule, we have that

$$l_1/\sin(\epsilon) = (\sqrt{x^2 + y^2})/\sin(\pi - \theta_2) = (\sqrt{x^2 + y^2})/\sin(\theta_2)$$

and thus

$$\sin(\theta_2) = \left(\sqrt{x^2 + y^2}\right)\sin(\epsilon)/l_1$$

The above equation could be used to solve for  $\theta_2$ . Alternatively, we can find  $\theta_2$  as follows.

Defining  $D$  to be  $(\sqrt{x^2 + y^2})\sin(\epsilon)/l_1$  we have that  $\cos(\theta_2) = \pm\sqrt{1 - D^2}$ . Then  $\theta_2$  can be found as

$$\theta_2 = \tan^{-1}\left[D/\pm\sqrt{1 - D^2}\right] \quad (14.3.6)$$

Notice that this method picks out both possible values of  $\theta_2$ , corresponding to the two possible inverse kinematic solutions. We now take the solution for  $\theta_2$  corresponding to the positive root of  $\pm(\sqrt{1 - D^2})$  (i.e., the bold robot configuration in the figure).

Using this solution for  $\theta_2$ , we can now solve for  $\theta_1$  and  $d_3$  as follows. Summing the angles inside the triangle in Figure 14.3.2, we obtain  $\pi - [(\pi - \theta_2) + \epsilon + \delta] = 0$  or

$$\delta = \theta_2 - \epsilon$$

From Figure 14.3.2 we see that

$$\theta_1 = \tan^{-1}(y/x) - \delta \quad (14.3.7)$$

Finally, use of the cosine rule leads us to a solution for  $d_3$ :

$$d_3^2 = l_1^2 + (x^2 + y^2) - 2l_1\left(\sqrt{x^2 + y^2}\right)\cos(\delta)$$

or

$$d_3 = \sqrt{l_1^2 + (x^2 + y^2) - 2l_1\left(\sqrt{x^2 + y^2}\right)\cos(\delta)} \quad (14.3.8)$$

Equations (14.3.6) to (14.3.8) comprise an inverse kinematics solution for the manipulator.

### Velocity Kinematics: The Manipulator Jacobian

The previous techniques, while extremely important, have been limited to positional analysis. For motion planning purposes, we are also interested in the relationship between joint velocities and task (end effector) velocities. The (linearized) relationship between the joint velocities  $\dot{q}$  and the end effector velocities  $\dot{Y}$  can be expressed (from Equation (14.3.1)) as

$$\dot{Y} = [J(q)]\dot{q} \quad (14.3.9)$$

where  $J$  is the *manipulator Jacobian* and is given by  $\partial f/\partial q$ . The manipulator Jacobian is an extremely important quantity in robot analysis, planning, and control. The Jacobian is particularly useful in determining singular configurations, as we shall see shortly.

Given the forward kinematic function  $f$ , the Jacobian can be obtained by direct differentiation (as in the example below). Alternatively, the Jacobian can be obtained column by column in a straightforward fashion from quantities in the Denavit-Hartenberg formulation referred to earlier. Since the Denavit-Hartenberg technique is almost always used in the forward kinematics, this is often an efficient and preferred method. For more details of this approach, see Spong and Vidyasagar (1989).

The Jacobian can be used to perform inverse kinematics at the velocity level as follows. If we define  $[J^{-1}]$  to be the inverse of the Jacobian (assuming  $J$  is square and nonsingular), then

$$\dot{q} = [J^{-1}(q)]\dot{Y} \quad (14.3.10)$$

and the above expression can be solved iteratively for  $\dot{q}$  (and hence  $q$  by numerical integration) given a desired end effector trajectory  $\dot{Y}$  and the current state  $q$  of the manipulator. This method for determining joint trajectories given desired end effector trajectories is known as Resolved Rate Control and has become increasingly popular. The technique is particularly useful when the positional inverse kinematics is difficult or intractable for a given manipulator.

Notice, however, that the above expression requires that  $J$  is both nonsingular and square. Violation of the nonsingularity assumption means that the robot is in a singular configuration, and if  $J$  has more columns than rows, then the robot is kinematically redundant. These two issues will be discussed in the following subsections.

#### Example 14.3.4

By direct differentiation of the forward kinematics derived earlier for our example,

$$\begin{bmatrix} \dot{x} \\ \dot{y} \\ \dot{\phi} \end{bmatrix} = \begin{bmatrix} -l_1 \sin(\theta_1) - d_3 \sin(\theta_1 + \theta_2) & -d_3 \sin(\theta_1 + \theta_2) & \cos(\theta_1 + \theta_2) \\ l_1 \cos(\theta_1) + d_3 \cos(\theta_1 + \theta_2) & d_3 \cos(\theta_1 + \theta_2) & \sin(\theta_1 + \theta_2) \\ 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} \dot{\theta}_1 \\ \dot{\theta}_2 \\ \dot{d}_3 \end{bmatrix} \quad (14.3.11)$$

Notice that each column of the Jacobian represents the (instantaneous) effect of the corresponding joint on the end effector motions. Thus, considering the third column of the Jacobian, we confirm that the third joint (with variable  $d_3$ ) cannot cause any change in the orientation ( $\phi$ ) of the end effector.

#### Singularities

A significant issue in kinematic analysis surrounds so-called singular configurations. These are defined to be configurations  $q_s$  at which  $J(q_s)$  has less than full rank (Spong and Vidyasagar, 1989). Physically, these configurations correspond to situations where the *robot joints* have been aligned in such a way that there is at least one direction of motion (the singular direction[s]) for the end effector that physically cannot be achieved by the mechanism. This occurs at workspace boundaries, and when the axes of two (or more) joints line up and are redundantly contributing to an end effector motion, at the cost of another end effector degree of freedom being lost. It is straightforward to show that the singular direction is orthogonal to the column space of  $J(q_s)$ .

It can also be shown that every manipulator must have singular configurations, i.e., the existence of singularities cannot be eliminated, even by careful design. Singularities are a serious cause of difficulties in robotic analysis and control. Motions have to be carefully planned in the region of singularities. This is not only because at the singularities themselves there will be an unobtainable motion at the end effector, but also because many real-time motion planning and control algorithms make use of the (inverse of the) manipulator Jacobian. In the region surrounding a *singularity*, the Jacobian will become ill-conditioned, leading to the generation of joint velocities in Equation (14.3.10) which are extremely high, even for relatively small end effector velocities. This can lead to numerical instability, and unexpected wild motions of the arm for small, desired end effector motions (this type of behavior characterizes motion near a singularity).

For the above reasons, the analysis of singularities is an important issue in robotics and continues to be the subject of active research.

**Example 14.3.5**

For our example manipulator, we can find the singular configurations by taking the determinant of its Jacobian found in the previous section and evaluating the joint configurations that cause this determinant to become zero. A straightforward calculation yields

$$\det(J) = l_1 \cos(\theta_1) \quad (14.3.12)$$

and we note that this determinant is zero exactly when  $\theta_1$  is a multiple of  $\pi/2$ . One such configuration ( $\theta_1 = \pi/2$ ,  $\theta_2 = -\pi/2$ ) is shown in [Figure 14.3.3](#). For this configuration, with  $l_1 = 1 = d_3$ , the Jacobian is given by

$$\begin{bmatrix} -1 & 0 & 1 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \end{bmatrix}$$

and by inspection, the columns of  $J$  are orthogonal to  $[0, -1, 1]^T$ , which is therefore a singular direction of the manipulator in this configuration. This implies that from the (singular) configuration shown in [Figure 14.3.3](#), the direction  $\dot{Y} = [0, -1, 1]^T$  cannot be physically achieved. This can be confirmed by considering the physical device (motion in the negative  $y$  direction cannot be achieved while simultaneously increasing the orientation angle  $\phi$ ).

**FIGURE 14.3.3** Singular configuration of planar RRP arm.

**Redundant Manipulator Kinematics**

If the dimension of  $q$  is  $n$ , the dimension of  $Y$  is  $m$ , and  $n$  is larger than  $m$ , then a manipulator is said to be *kinematically redundant* for the task described by  $Y$ . This situation occurs for a manipulator with seven or more degrees of freedom when  $Y$  is a six-dimensional position/orientation task, or, for example, when a six-degrees-of-freedom manipulator is performing a position task and orientation is not specified.

In this case, the robot mechanism has more degrees of freedom than required by the task. This gives rise to extra complexity in the kinematic analysis due to the extra joints. However, the existence of these extra joints gives rise to the extremely useful *self-motion* property inherent in redundant arms. A self-motion occurs when, with the end effector location held constant, the joints of the manipulator can move (creating an “orbit” of the joints). This allows a much wider variety of configurations (typically an infinite number) for a given end effector location. This added maneuverability is the key feature and advantage of kinematically redundant arms. Note that the human hand/arm has this property. The key question for redundant arms is how to best utilize the self-motion property while still performing specified

end effector motions  $Y$ . A number of motion-planning algorithms have been developed in the last few years for redundant arms (Siciliano, 1990). Most of them center on the Jacobian pseudoinverse as follows.

For kinematically redundant arms, the Jacobian has more columns than rows. If  $J$  is of full rank, and we choose  $[J^+]$  to be a pseudoinverse of the Jacobian such that  $JJ^+ = I$  [for example  $J^+ = J^T(JJ^T)^{-1}$ ], where  $I$  is the  $m \times m$  identity matrix, then from Equation (14.3.9) a solution for  $q$  which satisfies end effector velocity of  $Y$  is given by

$$\dot{q} = [J^+(q)]\dot{Y} + [I - J^+(q)J(q)]\epsilon \quad (14.3.13)$$

where  $\epsilon$  is an  $(n \times 1)$  column vector whose values may be arbitrarily selected. Note that conventional nonredundant manipulators have  $m = n$ , in which case the pseudoinverse becomes  $J^{-1}$  and the problem reduces to the resolved rate approach (Equation 14.3.10).

The above solution for  $\dot{q}$  has two components. The first component,  $[J^+(q)]\dot{Y}$ , are joint velocities that produce the desired end effector motion  $\dot{Y}$  (this can be easily seen by substitution into Equation (14.3.9)). The second term,  $[I - J^+(q)J(q)]\epsilon$ , comprises joint velocities which produce no end effector velocities (again, this can be seen by substitution of this term into Equation (14.3.9)). Therefore, the second term produces a self-motion of the arm, which can be tuned by appropriately altering  $\epsilon$ . Thus different choices of  $\epsilon$  correspond to different choices of the self-motion and various algorithms have been developed to exploit this choice to perform useful subtasks (Siciliano, 1990).

Redundant manipulator analysis has been an active research area in the past few years. A number of arms, such as those recently produced by Robotics Research Corporation, have been designed with seven degrees of freedom to exploit kinematic redundancy. The self-motion in redundant arms can be used to configure the arm to evade obstacles, avoid singularities, minimize effort, and a great many more subtasks in addition to performing the desired main task described by  $\dot{Y}$ . For a good review of the area, the reader is referred to Siciliano (1990).

### Example 14.3.6

If, for our example, we are only concerned with the position of the end effector in the plane, then the arm becomes kinematically redundant. Figure 14.3.4 shows several different (from an infinite number of) configurations for the arm given one end effector position. In this case,  $J$  becomes the  $2 \times 3$  matrix formed by the top two rows of the Jacobian in Equation (14.3.11). The pseudoinverse  $J^+$  will therefore be a  $3 \times 2$  matrix. Formation of the pseudoinverse is left to the reader as an exercise.

**FIGURE 14.3.4** Multiple configurations for RRP arm for specified end effector position only.

## Summary

Kinematic analysis is an interesting and important area, a solid understanding of which is required for robot motion planning and control. A number of techniques have been developed and are available to the robotics engineer. For positional analysis, the Denavit-Hartenberg technique provides a systematic approach for forward kinematics. Inverse kinematic solutions typically have been developed on a manipulator (or class of manipulator)-specific basis. However, a number of insightful effective techniques exist for positional inverse kinematic analysis. The manipulator Jacobian is a key tool for analyzing singularities and motion planning at the velocity level. Its use is particularly critical for the emerging generation of kinematically redundant arms

## 14.4 End Effectors and Tooling

*Mark R. Cutkosky and Peter McCormick*

*End effectors* or end-of-arm tools are the devices through which a robot interacts with the world around it, grasping and manipulating parts, inspecting surfaces, and working on them. As such, end effectors are among the most important elements of a robotic application — not “accessories” but an integral component of the overall tooling, fixturing, and sensing strategy. As robots grow more sophisticated and begin to work in more demanding applications, end effector design is becoming increasingly important.

The purpose of this chapter is to introduce some of the main types of end effectors and tooling and to cover issues associated with their design and selection. References are provided for the reader who wishes to go into greater depth on each topic. For those interested in designing their own end effectors, a number of texts including Wright and Cutkosky (1985) provide additional examples.

### A Taxonomy of Common End Effectors

Robotic end effectors today include everything from simple two-fingered grippers and vacuum attachments to elaborate multifingered hands. Perhaps the best way to become familiar with end effector design issues is to first review the main end effector types.

Figure 14.4.1 is a taxonomy of common end effectors. It is inspired by an analogous taxonomy of grasps that humans adopt when working with different kinds of objects and in tasks requiring different amounts of precision and strength (Wright and Cutkosky, 1985). The left side includes “passive” grippers that can hold parts, but cannot manipulate them or actively control the grasp force. The right-hand side includes active servo grippers and *dextrous* robot hands found in research laboratories and teleoperated applications.

FIGURE 14.4.1 A taxonomy of the basic end effector types.

#### Passive End Effectors

Most end effectors in use today are passive; they emulate the grasps that people use for holding a heavy object or tool, without manipulating it in the fingers. However, a passive end effector may (and generally should) be equipped with sensors, and the information from these sensors may be used in controlling the robot arm.

The left-most branch of the “passive” side of the taxonomy includes vacuum, electromagnetic, and Bernoulli-effect end effectors. Vacuum grippers, either singly or in combination, are perhaps the most commonly used gripping device in industry today. They are easily adapted to a wide variety of parts — from surface mount microprocessor chips and other small items that require precise placement to large, bulky items such as automobile windshields and aircraft panels. These end effectors are classified as “nonprehensile” because they neither enclose parts nor apply grasp forces across them. Consequently, they are ideal for handling large and delicate items such as glass panels. Unlike grippers with fingers, vacuum grippers do not tend to “center” or relocate parts as they pick them up. As discussed in [Table 14.4.1](#), this feature can be useful when initial part placement is accurate.

**TABLE 14.4.1 Task Considerations in End Effector Design**

---

<b>Initial Accuracy.</b> Is the initial accuracy of the part high (as when retrieving a part from a fixture or lathe chuck) or low (as when picking unfixtured components off a conveyor)? In the former case, design the gripper so that it will conform to the part position and orientation (as do the grippers in <a href="#">Figures 14.4.5</a> and <a href="#">14.4.6</a> . In the latter case, make the gripper center the part (as will most parallel-jaw grippers).
<b>Final Accuracy.</b> Is the final accuracy of the part high or low? In the former case (as when putting a precisely machined peg into a chamfered hole) the gripper and/or robot arm will need <i>compliance</i> . In the latter case, use an end effector that centers the part.
<b>Anticipated Forces.</b> What are the magnitudes of the expected task forces and from what directions will they come? Are these forces resisted directly by the gripper jaws, or indirectly through friction? High forces may lead to the adoption of a “wrap”-type end effector that effectively encircles the part or contacts it at many points.
<b>Other Tasks.</b> Is it useful to add sensing or other tooling at the end effector to reduce cycle time? Is it desirable for the robot to carry multiple parts to minimize cycle time? In such cases consider <i>compound end effectors</i> .
<b>Speed and Cycle Time.</b> Are speeds and accelerations large enough that inertial forces and moments should be considered in computing the required grip force?

---

If difficulties are encountered with a vacuum gripper, it is helpful to remember that problem can be addressed in several ways, including increasing the suction cup area through larger cups or multiple cups, redesigning the parts to be grasped so that they present a smoother surface (perhaps by affixing smooth tape to a surface), and augmenting suction with grasping as discussed below. [Figure 14.4.2](#) shows a large gripper with multiple suction cups for handling thermoplastic auto body panels. This end effector also has pneumatic actuators for providing local left/right and up/down motions.

An interesting noncontact variation on the vacuum end effector is illustrated in [Figure 14.4.3](#). This end effector is designed to lift and transport delicate silicon wafers. It lifts the wafers by blowing gently on them from above so that aerodynamic lift is created via the Bernoulli effect. Thin guides around the periphery of the wafers keep them centered beneath the air source.

The second branch of end effector taxonomy includes “wrap” grippers that hold a part in the same way that a person might hold a heavy hammer or a grapefruit. In such applications, humans use *wrap grasps* in which the fingers envelop a part, and maintain a nearly uniform pressure so that friction is used to maximum advantage. [Figures 14.4.4](#) and [14.4.5](#) show two kinds of end effectors that achieve a similar effect.

Another approach to handling irregular or soft objects is to augment a vacuum or magnetic gripper with a bladder containing particles or a fluid. When handling ferrous parts, one can employ an electromagnet and iron particles underneath a membrane. Still another approach is to use fingertips filled with an electrorheological fluid that stiffens under the application of an electrostatic field.

The middle branch of the end effector taxonomy includes common two-fingered grippers. These grippers employ a strong “pinch” force between two fingers, in the same way that a person might grasp a key when opening a lock. Most such grippers are sold without fingertips since they are the most product-specific part of the design. The fingertips are designed to match the size of components, the

**FIGURE 14.4.2** A large end effector for handling autobody panels with actuators for local motions. (Photo courtesy of EOA Systems Inc., Dallas, TX.)

**FIGURE 14.4.3** A noncontact end effector for acquiring and transporting delicate wafers.

**FIGURE 14.4.4** A compliant pneumatic gripper that executes a gentle wrap grasp. (From U.S. Patent No. 3981528, Simrit Corp., Arlington Hts., IL, 1984.)

**FIGURE 14.4.5** A gripper with pivoted fingers designed to conform to the position and orientation of heavy, irregular parts and to hold them securely. (From U.S. Patent No. 4,545,722, Cutkosky and Kurokawa, 1985.)

shape of components (e.g., flat or V-grooved for cylindrical parts), and the material (e.g., rubber or plastic to avoid damaging fragile objects).

Note that since two-fingered end effectors typically use a single air cylinder or motor that operates both fingers in unison, they will tend to center parts that they grasp. This means that when they grasp constrained parts (e.g., pegs that have been set in holes or parts held in fixtures) some compliance must be added, perhaps with a compliant wrist as discussed in “Wrists and Other End-of-Arm Tooling” below.

### Active End Effectors and Hands

The right-hand branch of the taxonomy includes servo grippers and dextrous multifingered hands. Here the distinctions depend largely on the number of fingers and the number of joints or degrees of freedom per finger. For example, the comparatively simple two-fingered servo gripper of [Figure 14.4.6](#) is confined to “*pinch*” grasps, like commercial two-fingered grippers.

Servo-controlled end effectors provide advantages for fine-motion tasks. In comparison to a robot arm, the fingertips are small and light, which means that they can move quickly and precisely. The total range of motion is also small, which permits fine-resolution position and velocity measurements. When equipped with force sensors such as strain gages, the fingers can provide force sensing and control, typically with better accuracy than can be obtained with robot wrist- or joint-mounted sensors. A servo gripper can also be programmed either to control the position of an unconstrained part or to accommodate to the position of a constrained part as discussed in [Table 14.4.1](#).

The sensors of a servo-controlled end effector also provide useful information for robot programming. For example, position sensors can be used to measure the width of a grasped component, thereby providing a check that the correct component has been grasped. Similarly, force sensors are useful for weighing grasped objects and monitoring task-related forces.

**FIGURE 14.4.6** A two-finger servo gripper with force sensing and changeable fingertips. (From E. Pearce et. al, ME210 Report, Stanford University, 1987.)

For applications requiring a combination of dexterity and versatility for grasping a wide range of objects, a dextrous multifingered hand is the ultimate solution. A number of multifingered hands have been described in the literature (see, for example, Jacobsen et al. [1984]) and commercial versions are available. Most of these hands are frankly anthropomorphic, although kinematic criteria such as work-space and *grasp isotropy* (basically a measure of how accurately motions and forces can be controlled in different directions) have also been used.

Despite their practical advantages, dextrous hands have thus far been confined to a few research laboratories. One reason is that the design and control of such hands present numerous difficult trade-offs among cost, size, power, flexibility and ease of control. For example, the desire to reduce the dimensions of the hand, while providing adequate power, leads to the use of cables that run through the wrist to drive the fingers. These cables bring attendant control problems due to elasticity and friction (Jacobsen et al., 1984).

A second reason for slow progress in applying dextrous hands to manipulation tasks is the formidable challenge of programming and controlling them. The equations associated with several fingertips sliding and rolling on a grasped object are complex — the problem amounts to coordinating several little robots at the end of a robot. In addition, the mechanics of the hand/object system are sensitive to variations in the contact conditions between the fingertips and object (e.g., variations in the object profile and local coefficient of friction). Moreover, during manipulation the fingers are continually making and breaking contact with the object, starting and stopping sliding, etc., with attendant changes in the dynamic and kinematic equations which must be accounted for in controlling the hand. A survey of the dextrous manipulation literature can be found in Pertin-Trocac (1989).

### Wrists and Other End-of-Arm Tooling

In many applications, an active servo gripper is undesirably complicated, fragile, and expensive, and yet it is desirable to obtain some of the compliant force/motion characteristics that an actively controlled gripper can provide. For example, when assembling close-fitting parts, compliance at the end effector can prevent large contact forces from arising due to minor position errors of the robot or manufacturing tolerances in the parts themselves. For such applications a compliant wrist, mounted between the gripper and the robot arm, may be the solution. In particular, *remote center of compliance (RCC)* wrists allow the force/deflection properties of the end effector to be tailored to suit a task. Active wrists have also been developed for use with end effectors for precise, high-bandwidth control of forces and fine motions (Hollis et al., 1988).

Force sensing and quick-change wrists are also commercially available. The former measure the interaction forces between the end effector and the environment and typically come with a dedicated microprocessor for filtering the signals, computing calibration matrices, and communicating with the robot controller. The latter permit end effectors to be automatically engaged or disengaged by the robot and typically include provisions for routing air or hydraulic power as well as electrical signals. They may also contain provisions for overload sensing.

### End Effector Design Issues

Good end effector design is in many ways the same as good design of any mechanical device. Foremost, it requires:

- A formal understanding of the functional specifications and relevant constraints. In the authors' experience, most design "failures" occurred not through faulty engineering, but through incompletely articulated requirements and constraints. In other words, the end effector solved the wrong problem.
- A "concurrent engineering" approach in which such issues as ease of maintenance, as well as related problems in fixturing, robot programming, etc., are addressed in parallel with end effector design.

- An attention to details in which issues such as power requirements, impact resistance, and sensor signal routing are not left as an afterthought.

Some of the main considerations are briefly discussed below.

### Sensing

Sensors are vital for some manufacturing applications and useful in many others for detecting error conditions. Virtually every end effector design can benefit from the addition of limit switches, proximity sensors, and force overload switches for detecting improperly grasped parts, dropped parts, excessive assembly forces, etc. These binary sensors are inexpensive and easy to connect to most industrial controllers. The next level of sophistication includes analog sensors such as strain gages and thermocouples. For these sensors, a dedicated microprocessor as well as analog instrumentation is typically required to interpret the signals and communicate with the robot controller. The most complex class of sensors includes cameras and tactile arrays. A number of commercial solutions for visual and tactile imaging are available, and may include dedicated microprocessors and software. Although vision systems are usually thought of as separate from end effector design, it is sometimes desirable to build a camera into the end effector; this approach can reduce cycle times because the robot does not have to deposit parts under a separate station for inspecting them.

### Actuation

The actuation of industrial end effectors is most commonly pneumatic, due to the availability of compressed air in most applications and the high power-to-weight ratio that can be obtained. The grasp force is controlled by regulating air pressure. The chief drawbacks of pneumatic actuation are the difficulties in achieving precise position control for active hands (due primarily to the compressibility of air) and the need to run air lines down what is otherwise an all-electric robot arm. Electric motors are also common. In these, the grasp force is regulated via the motor current. A variety of drive mechanisms can be employed between the motor or cylinder and the gripper jaws, including worm gears, rack and pinion, toggle linkages, and cams to achieve either uniform grasping forces or a self-locking effect. For a comparison of different actuation technologies, with emphasis on servo-controlled applications, see Hollerbach et al. (1992).

### Versatility

Figure 14.4.7 shows a how/why diagram for a hypothetical design problem in which the designer has been asked to redesign an end effector so that it can grasp a wide range of part shapes or types. Designing a versatile end effector or hand might be the most obvious solution, but it is rarely the most economical. A good starting point in such an exercise is to examine the end effector taxonomy in conjunction with the guidelines in Tables 14.4.1 and 14.4.2 to identify promising classes of solutions for the desired range of parts and tasks. The next step is to consider how best to provide the desired range of solutions. Some combination of the following approaches is likely to be effective.

*Interchangeable End Effectors.* These are perhaps the most common solution for grasping a wider array of part sizes and shapes. The usual approach is to provide a magazine of end effectors and a quick-change wrist so the robot can easily mount and dismount them as required. A similar strategy, and a simpler one if sensory information is to be routed from the end effector down the robot arm, is to provide changeable fingertips for a single end effector.

*Compound End Effectors.* These are a “Swiss army knife” approach that consists of putting a combination of end effectors on a single arm, or a combination of fingertips on a single end effector. As long as the end effectors or fingertips do not interfere with each other and the ensemble does not weigh too much for the robot arm, this solution combines the advantage of not having to pause to change end effectors with the advantages of custom-designed tooling. Figure 14.4.8 shows a compound end effector with tools for feeding, measuring, cutting, and laying down wires in a cable harness.

**FIGURE 14.4.7** A “how/why” diagram of solutions and rationale for a design problem involving a need to grasp a wide range of parts.

**TABLE 14.4.2 Part Characteristics and Associated End Effector Solutions**

<b>Size, weight</b>	
Large, heavy	Grippers using wrap grips, taking advantage of friction or <i>vacuum</i> or electromagnetic holding
Small, light	Two-fingered gripper; vacuum cup if smooth surface, electromagnet if ferrous alloy
<b>Shape</b>	
Prismatic	Two-fingered parallel-jaw gripper; angular motion if all parts have approximately same dimensions
Cylindrical	Parallel or angular motion two-finger gripper with V-jaw fingertips if light; wrap gripper if heavy; consider gripping on end with three-finger gripper if task or fixtures permit
Flat	Parallel or angular motion gripper or vacuum attachment
Irregular	Wrap grasp using linkages or bladder; consider augmenting grasp with vacuum or electromagnetic holding for heavy parts
<b>Surface</b>	
Smooth	Good for vacuum attachments, simple electromagnets, two-fingered grippers with flat fingertips
Rough	Compliant material (e.g., low durometer rubber) on fingertips or compliant membrane filled with powder or magnetic particles; grippers that use a wrap grasp are less sensitive to variations in surface quality
Slippery	Consider electromagnet or vacuum to help hold onto slippery material; grippers that use a wrap grasp are less sensitive to variations in friction
<b>Material</b>	
Ferrous	Electromagnet (provided that other concerns do not rule out the presence of strong magnetic fields)
Soft	Consider vacuum or soft gripping materials
Very delicate	Soft wrap grippers and vacuum grippers such as those in Figure 14.4.4 can grip very gently; compliant fingertips with foam rubber, or a membrane covering a powder, can also be used to distribute the contact pressure; if the part is very light and fragile consider lifting it using the Bernoulli effect

*Redesigned Parts and Fixtures.* Stepping back from the end effector, it is useful to recall that the design of the end effector is coupled with the design of fixtures, parts, and the robot. Perhaps we can design special pallets or adapters for the parts that make them simpler to grasp. Another solution is to standardize the design of the parts, using Group Technology principles to reduce the variability in sizes and geometries. When it is difficult to reduce the range of parts to a few standard families (or when the parts are simply hard to grip), consider adding special nonfunctional features such as tabs or handles so that a simple end effector can work with them.

**FIGURE 14.4.8** A “compound” end effector with tools for feeding, measuring, cutting, and laying down wires in a cable harness. (Photo courtesy of EOA Systems Inc., Dallas, TX.)

### Summary

In summary, we observe that end effector design and selection are inextricably coupled with the design of parts, robots, fixtures, and tooling. While this interdependence complicates end effector design, it also provides opportunities because difficult problems involving geometry, sensing, or task-related forces can be tackled on all of these fronts.

## 14.5 Sensors and Actuators

---

*Kok-Meng Lee*

Sensors and actuators play an important role in robotic manipulation and its applications. They must operate precisely and function reliably as they directly influence the performance of the robot operation. A transducer, a sensor or actuator, like most devices, is described by a number of characteristics and distinctive features. In this section, we describe in detail the different sensing and actuation methods for robotic applications, the operating principle describing the energy conversion, and various significant designs that incorporate these methods. This section is divided into four subsections, namely, tactile and proximity sensors, force sensors, vision, and actuators.

By definition, tactile sensing is the continuously variable sensing of forces and force gradients over an area. This task is usually performed by an  $m \times n$  array of industrial sensors called forcels. By considering the outputs from all of the individual forcels, it is possible to construct a tactile image of the targeted object. This ability is a form of sensory feedback which is important in development of robots. These robots will incorporate tactile sensing pads in their end effectors. By using the tactile image of the grasped object, it will be possible to determine such factors as the presence, size, shape, texture, and thermal conductivity of the grasped object. The location and orientation of the object as well as reaction forces and moments could also be detected. Finally, the tactile image could be used to detect the onset of part slipping. Much of the tactile sensor data processing is parallel with that of the vision sensing. Recognition of contacting objects by extracting and classifying features in the tactile image has been a primary goal. Thus, the description of tactile sensor in the following subsection will be focused on transduction methods and their relative advantages and disadvantages.

Proximity sensing, on the other hand, is the detection of approach to a workplace or obstacle prior to touching. Proximity sensing is required for really competent general-purpose robots. Even in a highly structured environment where object location is presumably known, accidental collision may occur, and foreign object could intrude. Avoidance of damaging collision is imperative. However, even if the environment is structured as planned, it is often necessary to slow a working manipulator from a high slew rate to a slow approach just prior to touch. Since workpiece position accuracy always has some tolerance, proximity sensing is still useful.

Many robotic processes require sensors to transduce contact force information for use in loop closure and data gathering functions. Contact sensors, wrist force/torque sensors, and force probes are used in many applications such as grasping, assembly, and part inspection. Unlike tactile sensing which measures pressure over a relatively large area, force sensing measures action applied to a spot. Tactile sensing concerns extracting features of the object being touched, whereas quantitative measurement is of particular interest in force sensing. However, many transduction methods for tactile sensing are appropriate for force sensing.

In the last three decades, computer vision has been extensively studied in many application areas which include character recognition, medical diagnosis, target detection, and remote sensing. The capabilities of commercial vision systems for robotic applications, however, are still limited. One reason for this slow progress is that robotic tasks often require sophisticated vision interpretation, yet demand low cost and high speed, accuracy, reliability, and flexibility. Factors limiting the commercially available computer vision techniques and methods to facilitate vision applications in robotics are highlights of the subsection on vision.

### Tactile and Proximity Sensors

A review of past investigations (see Nichols and Lee [1989] for details) has shown that a tactile sensor should have the following characteristics: most important, the sensor surface should be both compliant and durable, and the response of individual forcels should be stable, repeatable, free from hysteresis. The response must be monotonic, though not necessarily linear. The forcels should be capable of detecting

**TABLE 14.5.1 Advantages and Disadvantages of Different Tactile Transduction Methods**

Type	Advantages	Disadvantages
Resistive and conductive	Wide dynamic range Durability Good overload tolerance Compatibility with integrated circuitry	Hysteresis in some designs Limited spatial resolution Monotonic response, but often not linear
Capacitive	Wide dynamic range Linear response Robust	Susceptible to noise Temperature-sensitive Limiting spatial resolution
Magnetoelastic	Wide dynamic range Low hysteresis Linear response Robust	Susceptibility to stray fields and noise as circuitry requires
Optical	Very high resolution Compatible with vision technology No electrical interference problems	Some hysteresis, depends on elastomer in some designs
Piezoelectric and pyroelectric	Wide dynamic range Durability Good mechanical properties Capable of temperature as well as force sensing	Difficult to separate piezoelectric from pyroelectric effects Inherently dynamic
Thermal	Combined force and temperature	Slow in response

loads ranging from 0 to 1000 g, having a 1-g sensitivity, a dynamic range of 1000:1, and a bandwidth of approximately 100 Hz. Furthermore, forcers should be spaced no more than 2 mm apart and on at least a  $10 \times 10$  grid. A wide range of transduction techniques have been used in the designs of the present generation of tactile sensors. These techniques are compared in Table 14.5.1 and the principles of transduction methods are described as follows.

### Resistive and Conductive Transduction

This technique involves measuring the resistance either through or across the thickness of a conductive elastomer. As illustrated in Figure 14.5.1, the measured resistance changes with the amount of force applied to the materials, resulting from the deformation of the elastomer altering the particle density within it. Most commonly used elastomers are made from carbon or silicon-doped rubber, and the construction is such that the sensor is made up of a grid of discrete sites at which the resistance is measured.

A number of the conductive and resistive designs have been quite successful. A design using carbon-loaded rubber originated by Purbrick at MIT formed the basis for several later designs. It was constructed

**FIGURE 14.5.1** Resistive tactile element.

from a simple grid of silicon rubber conductors. Resistance at the electrodes was measured, which corresponds to loads. A novel variation of this design developed by Raibeit is to place the conductive sheet rubber over a printed circuit board (PCB) which incorporates VLSI circuitry, each force not only transduces its data but processes it as well. Each site performs transduction and processing operations at the same time as all the others. The computer is thus a parallel processor.

### Capacitive Transduction

Capacitive tactile sensors are concerned with measuring capacitance, which is made to vary under applied load. A common sensor design is to use an elastomeric separator between the plates to provide compliance such that the capacitance will vary according to applied load. The capacitance of a parallel plate capacitor is proportional to its congruous area and the permittivity of dielectric, and inversely proportional to the separation of the plates. Alteration of any of the three parameters causes a change of capacitance. Since the capacitance decreases with decreasing congruous area, the sensor becomes rather cumbersome for design of small force sensors.

To allow for a more compact design, an alternative tactile sensor array can be designed based on a moving dielectric element as illustrated in Figure 14.5.2. Each sensing element has two coaxial capacitor cylinders, acting as plates, fixed to a PCB. A dielectric element is spring-mounted in the space between the cylinders. The dielectric is displaced by contact with an external stimulus; hence it moves up and down between the capacitor plates as contact loads vary. A force-displacement relationship is thereby established.

FIGURE 14.5.2 Mechanical/capacitive tactile element.

A novel slip sensor using the change in capacitance caused by relative contact movement between sensor and object is described by Luo (Nichols and Lee, 1989). The contacting sensor surface comprises a set of parallel rollers. Each roller is a half cylinder of conductive material, and a half cylinder of nonconductive material. The rollers are mounted in a nonconductive material.

The casing and rollers act as a variable capacitor. A slipping object will rotate the rollers, causing the capacitance to change, which is then measured, thereby facilitating a slip sensor. The sensor measures the change of phase angle, with the amount of phase shift providing a measure of the scale of slip. A highly linear relationship between detected phase shift angle and sensor output was established.

### Magnetoelastic Transduction

Magnetoelastic sensors are a kind of inductive sensor that differs from those described above; they are not based on a change of geometry or on the position of conductive or capacitive materials. Instead, they are based on the Villari effect, consisting of reversible changes in the magnetization curve of a ferromagnetic material when it is subjected to a mechanical stress. It consists of changes of shape and volume during the magnetization process. Magnetoelastic materials undergo changes in their magnetic field when subjected to stress and therefore suggest themselves as possible transducers in tactile sensors.

Figure 14.5.3 illustrates this transduction principle in tactile sensor design. This method of tactile transduction has seen little development in robotics, although there are several papers on the subject (Fraden, 1993).

FIGURE 14.5.3 Magnetostrictive tactile element.

### Fiber Optics Proximity and Tactile Sensors

The development of optical fiber technology and solid-state cameras has led to some interesting new tactile sensor designs. The capability for high-spatial-resolution images, freedom from electrical interference, and ease of separation of sensor from processing electronics are some of the attractions of incorporating optical transduction methods into tactile sensors. The following illustrates two different fiber optic sensor designs, a proximity sensor and a tactile sensor.

Figure 14.5.4 illustrates the basic principle of fiber optic proximity sensor. Light from a light-emitting diode (LED) is passed down a fiber optic cable to illuminate any proximal objects. A second cable picks up any reflected light from illuminated objects within a detection zone and directs it onto a photodiode. This simple technique can be built into a finger. The finger can sense contacts perpendicular to the finger axis, radially, and also axial contact at the fingertip. Several fiber optic cable pairs can be evenly spaced around the fingers and incorporated into a gripping system. Figure 14.5.4 illustrates this transduction method for proximity sensing.

FIGURE 14.5.4 Optical proximity sensing.

Optical fibers are a type of dielectric waveguide. These waveguides channel light energy by “trapping” it between cylindrical layers of dielectric materials. In the most simple case, the fiber core is surrounded by a cladding which has a small refractive index. Light is lost from the core of a fiber when a mechanical bend or perturbation results in coupling between guided and radiation modes. The concept of monitoring light losses due to microbending can be found in several tactile sensor designs (Nichols and Lee, 1989; Tzou and Fukuda, 1992).

### Piezoelectric/Pyroelectric Effect

The piezoelectric effect is the generation of a voltage across the sensing element when pressure is applied to it. Correspondingly, the pyroelectric effect is the generation of a voltage when the sensing element is heated or cooled. No external voltage is required, and a continuous analog output is available from such a sensor. Such sensors are most suited for sensing pressure changes or thermal variations. Figure 14.5.5 shows a design based on the piezoelectric effect for robotic applications (Fraden, 1993). The

**FIGURE 14.5.5** Schematic of piezoelectric sensor for a soft fingertip.

sensor includes piezoelectric strips directly interfaced with a rubber skin; thus the electric signal produced by the strips reflects movements of the elastic rubber which results from the friction forces.

### Thermal Tactile Sensors

The thermal sensor (Nichols and Lee, 1989) is based on the detection of the change of thermal properties through contact of an object. The main function of the thermal sensor is to provide information about the material makeup of objects. The essential parts of each element of the thermal sensor are a heat source (such as a power transistor), a layer of material of known thermal conductivity (for example, copper) to couple the heat source to the touched object, and a temperature transducer (thermistor) to measure the contact-point temperature. The response time of the thermal sensor is relatively slow, typically in the order of several seconds. However, images representing the material constitution of the touching objects provide useful tactile data.

### Force Sensors

Force sensors measure the force and represent its value in terms of an electrical signal. Examples of these sensors are strain gauges and load cells.

#### Strain Gauge-Based Force Sensor

A strain gauge is a resistive elastic sensor whose resistance is a function of applied strain or unit deformation. The relationship between the normalized incremental resistance and the strain is generally known as the piezoresistive effect. For metallic wire, the piezoresistance ranges from 2 to 6. For semiconductor gauges, it is between 40 and 200. Many metals can be used to fabricate strain gauges. Typical resistances vary from 100 to several thousand ohms. Strain gauges may be arranged in many ways to measure strains and are used typically with Wheatstone bridge circuits. As strain gauges are often sensitive to temperature variations, interfacing circuits or gauges must contain temperature-compensating networks.

Strain gauges are commonly used for six-degrees-of-freedom force/torque wrist sensors, force probes, flexural assemblies for force control, and micromotion detection. The Scheinman force-sensing wrist is a Maltese cross design, with one strain gauge mounted on each of the 16 faces of the cross-webbing. The gauges are operated in eight voltage-divider pairs to measure distortions, and therefore forces, in six degrees of freedom in the hand coordinate system.

#### Other Force Sensors

Other methods include the vacuum diode force sensor, quartz force sensor, and piezoelectric force sensor. A piezoelectric sensor converts mechanical stress into an electric signal (Fraden, 1993). It is sensitive to changing stimuli only and insensitive to a constant force. As shown in [Figure 14.5.6](#), the sensor consists of three layers where the PVDF film is laminated between a backing material (for example, silicon rubber) and a plastic film. When the PVDF is stressed, it results in a generation of electric charge

FIGURE 14.5.6 Piezoelectric force rate sensor.

flowing out of the film through a current-to-voltage (I/V) converter. The resulting output voltage is proportional to the applied force.

Figure 14.5.7 shows a typical structure fabricated by micromachining technology in a silicon wafer. As shown in the figure, the diode sensor has a cold field emission cathode, which is a sharp silicon tip, and a movable diaphragm anode. When a positive potential difference is applied between the tip and the anode, an electric field is generated which allows electrons to tunnel from inside the cathode to the vacuum. The field strength at the tip and quantity of electrons emitted (emission current) are controlled by the anode potential. When an external force is applied, the anode deflects and changes the field and the emission current.

FIGURE 14.5.7 Schematic of a vacuum diode force sensor.

Figure 14.5.8 shows a quartz crystal force sensor. A quartz crystal is often used as a resonator in electrical oscillators. The basic idea behind the quartz force sensor's operation is that certain cuts of quartz crystal shift the resonant frequency when mechanically loaded.

FIGURE 14.5.8 Quartz force sensor.

### Vision

Many industrial tasks require sophisticated vision interpretation, yet demand low cost, high speed, accuracy, and flexibility. To be fully effective, machine vision systems must be able to handle complex industrial parts. This includes verifying or recognizing incoming parts and determining the location and orientation of the part within a short cycle time. Typical video-based vision systems conform to the RS-170 standard established in the 1950s, which defines the composite video and synchronizing signal that

the television industry uses. It specifies a standard frame rate for visual interpretation. The components required for building a video-based vision system generally include a video camera which outputs standard RS170 video signal, a frame grabber board which uses a flash analog-to-digital (A/D) converter to change the RS170 video signal into a series of  $n$  bit brightness values (gray levels) and fast memory components to store them, and a microcomputer which processes the images and computes the location and orientation of the part. See Ballard and Brown (1982) for information on vision processing techniques.

In addition to the error resulting from the timing mismatching between image acquisition hardware and the computer hardware, the RS170 video signal limits the readout of a complete frame at a rate of 30 fps (frames per second). An image of  $m$  rows by  $n$  columns has  $m \times n$  *pixels* and so requires a substantial amount of memory and loading time. Among these  $m \times n$  pixels, only a few carry the information on which a vision system will base a decision. This generally makes “frame grabbing” inherently wasteful.

Apart from the lack of appropriate hardware and the high equipment cost for robotic applications, a major problem often associated with the use of the RS170 video vision system is the excessive image processing time which depends on the illumination technique, the complexity of the geometry, and the surface reflectance of both the background and the objects to be handled.

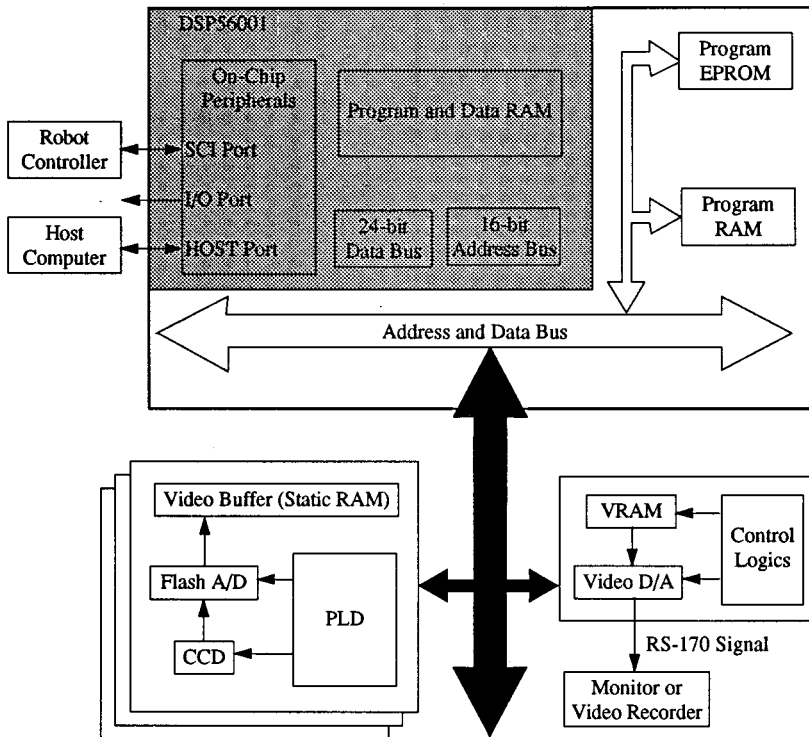

### Flexible Integrated Vision System

To overcome these problems, several vision systems were designed for robotic applications. Among these is a Flexible Integrated Vision System (FIVS) developed at Georgia Tech (Lee and Blenis, 1994), which offers performance and cost advantages by integrating the imaging sensor, control, illumination, direct digitization, computation, and data communication in a single unit. By eliminating the host computer and frame grabber, the camera is no longer restricted by the RS-170 standard and thus frame rate higher than 30 fps can be achieved.

*Flexible Integrated Vision System Hardware.* As shown in [Figure 14.5.9](#), the central control unit of the flexible integrated vision system is a microprocessor-based control board. The design is to have all of the real-time processing performed using the microprocessor control board without relying on any other system or computer. Thus, it is desired to have the following features: (1) the microprocessor has an on-chip program memory and independent on-chip data memories. These memories must be externally expandable and accessible with zero wait states; (2) it has independent execution units which are connected by independent buses to the on-chip memory blocks. This feature provides the parallelism needed for high performance digital signal processing and high-powered computation of mathematically intensive algorithms. For these reasons, a digital signal processor (DSP) chip has been chosen.

The DSP-based control board is designed to communicate with several option boards in parallel to tailor the system for a number of applications. Each of these option boards is controlled independently by a programmable logic device (PLD) which receives a peripheral select signal, a read/write signal, and an address signal from the microprocessor control board. Typical examples of the option boards for the FIVS are the digital video head, a real-time video record/display/playback board, and an expandable memory board.

The video head consists of a  $m \times n$  CCD array, the output of which is conditioned by high bandwidth amplification circuitry. The output is then sampled by a “flash” analog-to-digital converter (ADC). The DSP-based control board provides a direct software control of CCD array scanning and integration time, the intensity of the collocated illumination, and the real-time execution of a user-selectable vision algorithm imbedded in the EEPROM. In operation, the PLD decodes the control signals to initiate row shifts and column shifts in response to commands from the DSP-based control board. Particular row shifts and column shifts enable retrieving only a specific relevant area from an image. The PLD also provides control signals to ADC for performing the analog-to-digital conversion synchronized with row shifts, and enables the video buffer when the DSP reads or writes data to the VRAM.

**FIGURE 14.5.9** Schematic of a flexible integrated vision system.

Unlike conventional RS170-based systems which require pixel data to be stored in a video buffer before processing of pixel data can commence, the FIVS design provides an option to completely bypass the video buffer and thus offers a means to process and/or to store the digitized pixel data by directly transferring the ADC output to the DSP. For real-time vision-based object tracking and motion control system applications, the scheme represents a significant saving in time and video buffer size required for processing an image. As an illustration, consider an image array of  $m \times n$  pixels. The time needed to store the entire image (with no computation) in a memory at  $K$  MHz is  $(m \times n)/K$  s and requires  $(m \times n)$  bytes of memory. Typical array size of a CCD ranges from  $200 \times 160$  to  $4096 \times 4096$  of pixels. The corresponding video buffer and time required simply to store the entire image at a clock rate of 10 MHz would range from 32K bytes to 16 Mbytes and 3.2 to 1600 msec, respectively! Clearly, the option to completely bypass the video buffer offers a potentially useful solution to eliminate the frame storage prerequisite which is often required in conventional vision systems. Furthermore, this scheme completely eliminates the special hardware needed in acquiring the digitized pixel data for storage.

*Flexible Integrated Vision System Imbedded Software.* The vision system imbedded software includes the following functions. The first function is to give users the flexibility to control the CCD array scanning, integration time, and the intensity of the illumination. With the CCD under software control, partial frames can be “captured” instead of the customary full frame, reducing the cycle time required to capture and process an image. The ability to shift out partial frames is ideal for high-speed tracking applications where the approximate location is known from a prior image. By reducing the time to capture an image, the effective frame rate is increased. For example, shifting out 1/4 of an image can increase the frame rate up to 480 fps, not including the time required for illumination and image processing. This frame rate is 16 times the rate achievable from the RS-170 standard.

The second function is to offer an option to process the pixel data from the ADC directly without having to store the pixel data prior to processing. Although windowing process methods have been

suggested to perform object tracking under software control, these methods required that a partial window is stored before scanning can begin. The differences between the direct computation and the windowing process for object tracking are as follows: (1) in windowing process, the entire image must be stored and analyzed at least once before any subsequent windowing process can be performed in order to provide a reasonable estimate of the object location. Furthermore, if the initial field of view does not contain the object, this estimate must be repeated until an approximate area containing the object can be reasonably found. This prerequisite of storing the image is not necessary if the pixel data are directly processed; (2) after the initial estimate, a fixed window which must be sufficiently large in order to include the object in the field of view must be specified in the windowing process. In most conventional systems which output their ADC to the video buffer directly, a partial frame of the image as specified by the window must be stored. By providing a direct transfer the ADC output to the DSP and thus eliminating the windowing storing process, a significant fraction of time can be saved. This function provides an attractive feature to vision-based motion control applications.

The third function allows image processing to be performed in real time without a host computer. The algorithm that allows the user to customize the system for a specified task is preprogrammed in the EEPROM (electrically erasable programmable read only memory). Because it is impractical to preprogram every possible vision processing algorithm into the FIVS camera, it is desirable that the system can be reprogrammed easily. The main kernel provides a user interface whereby the user can customize the real-time processing for a particular task, from a library of algorithms. This function also provides an effective means to resolve software implementation issues prior to an on-line application. By previewing images of a sample part, the user may select an appropriate vision algorithm for an accurate computation of the location and orientation in real time. Once the algorithms and data are downloaded into the on-board EEPROM, the FIVS can function as an intelligent sensor and communicate directly with the robot controller without a host computer.

The fourth function, which incorporates a real-time display, allows the process controller to set up, to calibrate the vision system, or to analyze a failure mode (if any).

### **Illumination Considerations**

Imaging sensors are characterized by their specific bandwidths or wavelengths of light which maximize the response of the sensor and will provide it an optimum operating environment. It is desired that the photodetector responds only to the light from the illumination source structured for the object but not that of ambient lighting. Otherwise, software compensation must be considered. To accomplish the objective, a typical sensor/illumination system design must consider the spectral matching of the camera imaging sensor/filter and a spectral illuminator while minimizing the effect of the ambient lighting.

*Spectral Responsivity of Sensor.* The two most commonly used camera imaging sensors are the charge-coupled device (CCD) and the charge injection device (CID). The CCD is responsive to wavelengths of light from below 350 nm (ultraviolet) to 1100 nm (near infrared) and has a peak response approximately at 800 nm. The CID offers a similar spectral response and has a peak spectral response about 650 nm. The relative response of a vidicon camera, however, depends significantly on the materials.

*Spectral Characteristic of Typical Ambient Lighting.* Depending on the spectral emissions of illumination sources used as general lighting in the factory environment, the influences of the ambient lighting can be effectively minimized or eliminated by means of spectral filtering. Gas discharge lamps generally have relatively high emission in the visible range and have little or no emission for wavelengths larger than 800 nm. Sun, tungsten lamps, and quartz-halogen-type lamps have a wide spectral emission.

*Illumination Source.* The spectral characteristics of three different spectral sources, namely, laser diodes, light-emitting diode (LED), and xenon strobes, are of particular interest since the spectral wavelengths of these sources well match the optimal response of the CCD and/or CID detectors. Pulsed GaAlAs laser diodes emit single frequency power in the 790- to 850-nm wavelength range. Irradiance at spectral wavelength in the range of 810 to 830 nm can also be produced from a xenon lamp. An

**TABLE 14.5.2 Comparison Between Three Spectral Light Sources**

Source	Wavelength (nm)	Unit cost (US \$)	Life	Power
LED	570–630	1.00	5,000,000 hours (MTBF)	100 mW
Laser diode	790–840	200.00	250,000 hours (MTTF)	1 W (peak pulse power)
Xenon flashtubes	830–1000	10.00	1,000,000 flashes (0.3–4 flashes/sec)	25 W (500 V nominal)

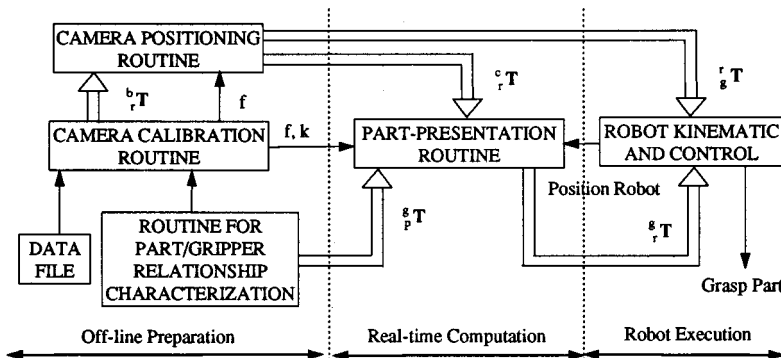

AlGaAs LED is designed to concentrate the luminous flux into a narrow radiation pattern to achieve a narrow high peak intensity. A comparison of these sources is provided in Table 14.5.2.

*Object and Background Reflectance.* If the orientation of the parts can be characterized by the two-dimensional object silhouette and the environment can be structured, back lighting can be used to create silhouettes of the object. Alternatively, retroreflective materials (Lee and Blenis, 1994) can be used to create a unique background. Since most of the incident illuminance from the object is reflected or diffused away from the aperture, whereas that on the background surface is retroreflected, the object appears as a dark silhouette against a reliable bright-field background.

Retroreflective materials can be used as background in part presentation or as a landmark on parts. The choice clearly depends on the part design and manufacturing process. The most common retroreflective surface is in the form of sheeting due to its reliability and ease of application. Flexible retroreflective sheeting is made of countless microcube-corners or spheres enclosed in a weather-resistant transparent plastic film. Pigment or dye can be inserted into the film or the reflecting surface to reflect color. Four typical retroreflective sheetings are described as follows: (1) cube-corner retroreflective sheeting, (2) exposed glass beads, (3) enclosed glass beads, and 4) encapsulated glass beads. A detailed study of retroreflective sensing for robotic applications is given by Lee and Li (Lee and Blenis, 1994).

**Vision Algorithms for Robotic Applications**

Figure 14.5.10 illustrates a vision system for robotic part pickup applications (see also Section 14.9). Here the camera is mounted along with the gripper on the end effector mount of the robot. This allows complete freedom in positioning and orienting the camera for viewing. Placing the camera on the last link of a six-DOF robot enables the machine vision to view objects (parts) individually. The camera is oriented so that its line of sight is perpendicular to the plane on which the part is placed. However, at each position, the 3D position and orientation of the feature measured by the vision system are only relative to the vision sensor. The robot is driven by sensory information from the vision system as well as inputs from the off-line calibration.

**FIGURE 14.5.10** Vision system for robotic applications.

Thus, the basic components of the vision system for robotic part pickup include (1) system calibration, (2) image segmentation and feature extraction, and (3) communication protocol.

*System Calibration.* In order to determine the 3D position and orientation of the feature with respect to robot world coordinate, it is necessary to calibrate the relative homogeneous transformation between the two coordinate frames, one centered at the camera and the other at the gripper. Thus, the system calibration is to establish the relationship between the 3D world coordinates as seen by the robot and their corresponding 2D image coordinates as seen by the computer. The calibration algorithm consists of off-line calibrating the intrinsic parameters of the camera and the camera-gripper relationship and on-line calibrating the pallet location. The camera calibration technique originally established by Tsai and Lenz (1989) has been the basis for several later calibration routines.

*Image Segmentation and Feature Extraction.* Most existing industrial-vision systems and algorithms extract features from industrial objects against a high contrast background with controlled lighting. The processing of feature extraction usually begins by generating a binary image from the original gray-scale image by choosing an appropriate threshold. To eliminate noise caused by electromagnetic interference, and ignoring the other objects in the field of view, image segmentation is performed before the computation of the part location and orientation. An image segmentation algorithm is written to locate regions of pixels that are connected and to label each region (object) so that it can easily be picked out from the other regions in the image. After segmentation is complete, only the largest object in the image is examined for its features.

There are many practical methods for the identification of a given object in a scene. A part-recognition system consists of three major components, namely, feature extraction, object modeling, and matching. Most industrial parts-recognition systems are model-based systems in which recognition involves matching the input image with a set of predefined models of part. Models based on geometric properties of an object's visible surfaces or silhouette are commonly used because they describe objects in terms of their constituent shape features. Image features such as edge, corner, line, curve, hole, and boundary curvature define individual feature components of an image. Given a set of models that describes all aspects of all parts to be recognized, the process of model-based recognition consists of matching features extracted from a given input image with those of the models. There are many practical methods for identification of a given object in a scene. A tutorial on binary image processing for robot-vision applications is given by Kitchin and Pugh (1983). A more general comparative study of model-based object-recognition algorithms for robot vision is described by Chin and Dyer (1986).

*Communication Protocol.* To ensure data integrity during communications, DEC's Digital Data Communications Message Protocol (DDCMP) is used for communications with the vision system. DDCMP is an industrial standard communication protocol that is used to communicate with industrial robots. DDCMP ensures a reliable communications link with a minimum amount of overhead. DDCMP precedes all data transmissions with a header block describing the type of message and the length of any message data that follows.

## Actuators

Actuators used for robotic manipulators can be broadly classified as follows: (1) electromechanical actuators, (2) fluid power actuators, and (3) new alternative actuators. [Table 14.5.3](#) summarizes a further subdivision based on their operating principles. The choice of actuators for robotic applications depends on specific tasks. Relative comparisons to guide selection of common actuators are given in [Table 14.5.4](#) and [Figure 14.5.11](#), which shows the force vs. speed comparison for common actuators.

### Direct-Drive Joint Motor

The direct-drive joint motor has been developed to eliminate the transmission mechanism between the motor and the links, thus eliminating friction and backlash introduced by gear motors. This results in an arm suitable for high-speed, fine torque control. A direct, drive design also allows for elegant

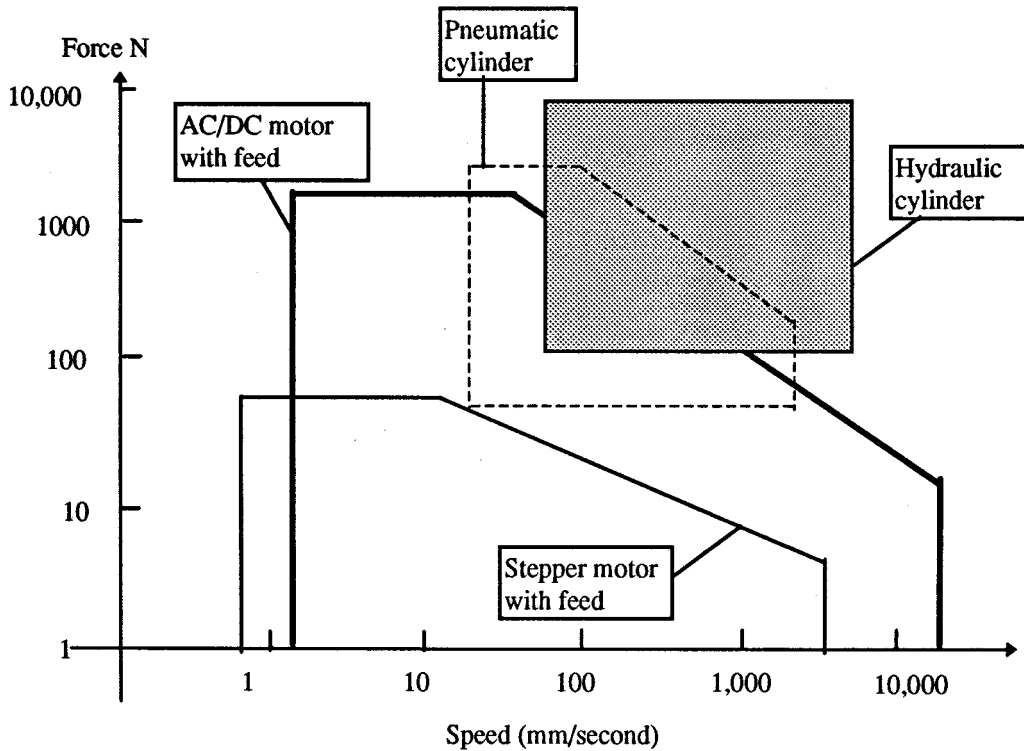

**TABLE 14.5.3 Lower Power Actuator Principles**

**FIGURE 14.5.11** Force vs. speed for common actuators.

mechanical construction. All of the joints in a direct-drive arm are essentially identical in structure, consisting of a motor, a shaft encoder, bearings, and a housing. These components are mounted on a single shaft; a single bearing is used in the entire joint assembly. As a result, a direct drive joint generally has few but compact and more easily manufactured components than a gear-driven joint, an attractive feature for commercial production of arms.

**Shape Memory Alloy (SMA) Wire**

The properties of the shape memory alloy are associated with appearance and disappearance of martensite in the alloy structure. There are two kinds of martensites, namely, thermal martensite which is generated by cooling the shape memory alloy below martensite transition temperature, and stress-induced martensite which is generated by loading the stress on a shape memory alloy having an austenite structure. Shape memory effect (SME) is associated with the former, and superconductivity (SE) is associated with the latter. By making use of SME and SE, it is possible to use the shape memory alloy as an element of the actuator of a joint mechanism as shown in Figures 14.5.12 and 14.5.13. In Figure 14.5.12, mass 1 is driven toward the right side by heating the SMA wire A and cooling SMA wire B. Similarly, by reversing the direction of the heating and cooling, mass 1 can be made to move toward the left. An alternative SMA wire-actuated revolute joint using an ordinary spring is shown in Figure 14.5.13. The shape memory alloy joint mechanism has the advantage of being light in weight and simple. However, it generally has a relatively low efficiency and is slow in response.

**FIGURE 14.5.12** Model illustrating SME wire for joint mechanism.

**FIGURE 14.5.13** Schematic illustrating SME wire for revolute joint.

An increasing need for high performance robotic applications has motivated several researchers to direct their investigation efforts to new actuator concepts. In some applications such as high-speed plasma, water-jet and laser cutting, active joystick, and coordinate-measuring machines, the demands on workspace and the wrist force/torque are low, but the end effector must be oriented quickly, continuously, and isotropically in all directions. The performance of the popular three-consecutive-rotational-joints wrist, which possesses singularities within its workspace, is less than optimum. Several alternative designs have been developed, which present some attractive possibilities by combining pitch, roll, and yaw motion in single balljoint-like actuators. Among these design concepts are the spherical induction motor, the DC spherical servo motor, and the variable-reluctance (VR) spherical motor. Major developments for robotics are given as follows.

**Spherical Induction Motor**

In a spherical induction motor, three sets of windings are necessary to realize rotation about an arbitrary axis. The three windings are positioned to give rotations about the x, y, and z axes. By independently controlling the strength and phase of any two windings, one can realize a rotation vector at any point in the rotation plane of the two windings. Analyses of fields and torques in the spherical induction motor have been performed; however, realization of a prototype spherical induction motor remains to be

demonstrated. The mechanical design of a spherical motor is complex. Laminations are required to prevent unwanted eddy currents. Complicated three-phase windings must be mounted in recessed grooves in addition to the rolling supports for the rotor in a static configuration.

### Spherical DC Servo Motor

The rotor of a spherical DC servo motor is a disk comprising a yoke with four permanent magnets attached to its periphery. The pivot bearing is constructed of three small radial ball bearings and has three DOF. Therefore, the rotor can incline and rotate around the three axes of Cartesian coordinates relative to the stator. The inclined and rotated angles are detected by rotary encoders attached to each axis. Three sets of windings are set at  $30^\circ$  apart around the z axis such that four electromagnetic force vectors can be obtained at the locations where the currents intersect the magnetic flux. They are controlled like three separated brushless motors. Although the DC spherical motor is characterized by its constructional simplicity, the range of inclination and the torque constant are rather limited.

### Variable-Reluctance (VR) Spherical Motor

The structure of a VR spherical motor is shown in Figure 14.5.14, which consists of three subassemblies: a rotor, a stator, and a measuring system. The rotor is a smooth sphere in which  $m$  magnetic poles are embedded. The stator is a hollow sphere with  $n$  stator coils radially mounted on its inner surface. It also serves as a structure that holds together all the other functional elements which include the stator coils, the bearing, and the measurement system.

FIGURE 14.5.14 Schematic illustrating VR spherical motor.

In the operation of the VR spherical motor, the stator coils are energized individually using the control circuitry. A magnetic field is established which stores magnetic energy in the airgaps. The stored energy is a function of the relative position of the rotor and the stator. The motion of the spherical motor is thus generated as the rotor tends to move to a position such that the energy in the airgap is minimized. The VR spherical motor is characterized by the following features: (1) it offers a potential advantage of distributing the input power among several coils, each of which contributes a small fraction of the total mmf's required to generate a specified torque, and, thus, it allows a relatively low current per coil but a large surface area for heat dissipation; (2) there are multiple solutions to the selection of coil excitations, which allow an optimal electrical input vector to be chosen to minimize a preselected cost function.

As compared to its counterpart, a VR spherical motor has a relatively large range of inclination, possesses isotropic properties in motion, and is relatively simple and compact in design. The tradeoff, however, is that a sophisticated control scheme is required.

**Multi-DOF Microactuators**

Silicon exhibits very useful mechanical properties and its applications to microsensors and actuators have been extensively researched around the world. The fabrication of silicon-based components typically employs micromachining. Thin film and photolithographic fabrication procedures make it possible to realize a great variety of extremely small, high precision mechanical structures using the same processes that have been developed for electronic circuits. This technology has enabled the realization of many innovative microactuators operating on the basis of electrostatic to mechanical transduction.

## 14.6 Robot Programming Languages

---

*Ron Bailey*

The earliest industrial robots were simple sequential machines controlled by a combination of servo motors, adjustable mechanical stops, limit switches, and programmable logic controllers. These machines were generally programmed by a record and play-back method with the operator using a teach pendant to move the robot through the desired path. MHI, the first robot programming language, was developed at MIT during the early 1960s. It was an interpreted language which ran on a TX-O computer. WAVE, developed at Stanford during the early 1970s, was a general-purpose language which ran as an assembler on a DEC PDP-10 minicomputer. MINI, developed at MIT during the mid-1970s, was an expandable language based on LISP. It allowed programming in Cartesian coordinates with independent control of multiple joints. AL (Mujtaba, 1982), developed at Stanford, included some programming features of ALGOL and Pascal. VAL and VAL II (Shimano et al., 1984), developed by Unimation, Inc., was an interpreted language designed to support the PUMA series of industrial robots.

*AML* (A Manufacturing Language) (Taylor et al., 1982) was a completely new programming language developed by IBM to support the R/S 1 assembly robot. It was a subroutine-oriented, interpreted language which ran on the Series/1 minicomputer. Later versions were compiled to run on IBM-compatible personal computers to support the 7535 series of SCARA robots. MCL, developed by McDonnell Douglas, was an extension of the *APT* language (Automatic Programming of Tools) originally written for numerically controlled machine tools. RAIL, developed by AUTOMATIX, Inc., was an extension of Pascal designed to control robot welding and vision systems. Several additional languages (Gruver et al., 1984; Lozano-Perez, 1983) were introduced during the late 1980s to support a wide range of new robot applications which were developed during this period.

V+, developed by Adept Technologies, Inc., is a representative modern robot programming language. It has several hundred program instructions and reserved keywords. V+ will be used in the following sections to demonstrate important features of robot programming.

### Robot Control

Program instructions required to control robot motion specify location, trajectory, speed, acceleration, and obstacle avoidance. Examples of V+ robot control commands are as follows:

MOVE	Move the robot to a new location
APPRO	Move to a location set back from a named position
DEPART_	Back away from the current location
DELAY	Stop the motion for a specified period of time
SPEED	Set the speed for subsequent motions
ACCEL	Set the acceleration and deceleration for subsequent motions
SINGLE	Limit motion of a joint
MULTIPLE	Allow full motion of the wrist joints
OPEN_	Open the hand
CLOSE_	Close the hand
RELAX_	Turn off air pressure to the hand

### System Control

In addition to controlling robot motion, the system must support program editing and debugging, program and data manipulation, program and data storage, program control, system definitions and control, system status, and control/monitoring of external sensors. Examples of V+ control instructions are as follows:

EDIT	Initiate line-oriented editing
SEE	Initiate screen-oriented editing

STORE_	Store information from memory onto a disk file
LOAD	Read the contents of a disk file into memory
COPY	Copy an existing disk file into a new program
SPEED	Set the overall speed of robot motions
EXECUTE	Initiate execution of a program
ABORT	Stop program execution
DO	Execute a single program instruction
WATCH	Set and clear breakpoints for diagnostic execution
WHERE	Display current robot location
TEACH	Define a series of robot location variables
CALIBRATE	Initiate the robot positioning system
STATUS	Display the status of the system
TIME	Set and display current date and time
ENABLE	Turn on one or more system switches
DISABLE	Turn off one or more system switches

## Structures and Logic

Program instructions are needed to organize and control execution of the robot program and interaction with the user. Examples include the following:

FOR	Execute a group of instructions a number of times
WHILE	Continue execution of a group of instructions until a condition is satisfied
DO	Execute a group of instructions until a condition is satisfied
IF	Control whether a group of instructions is executed
TYPE	Output a message to the terminal
ATTACH	Make the control pendant active
WRITE	Output a message to the manual control pendant
PENDANT	Receive input from the manual control pendant
PARAMETER	Set the value of a system parameter

## Special Functions

Various special functions are required to facilitate robot programming. These include mathematical expressions and instructions for data conversion, manipulation, and transformation. Examples are as follows:

ABS	Absolute value
COS	Cosine function
SQRT	Square root
BCD	Convert from real to Binary Coded Decimal
DCB	Convert from binary to real
FRAME	Compute the reference frame based on given locations
TRANS	Compose a transformation from individual components
INVERSE	Return the inverse of the specified transformation

## Program Execution

Organization of a program into a sequence of executable instructions requires scheduling of tasks, control of subroutines, and error trapping/recovery. Examples include the following:

PCEXECUTE	Initiate the execution of a process control program
PCABORT	Stop execution of a process control program

PCPROCEED	Resume execution of a process control program
PCRETRY	After an error, resume execution at the last step tried
PCEND	Stop execution of the program at the end of the current execution cycle

## Example Program

This program demonstrates a simple pick and place operation.

```

1 .PROGRAM move.parts()
2 ; Pick up parts at location "pick" and put them down at "place"
3 parts = 100 ; Number of parts to be processed
4 height1 = 25 ; Approach/depart height at "pick"
5 height2=50;
   Approach/depart height at "place"
6 PARAMETER.HAND.TIME = 16 ; Setup for slow hand
7 OPEN ; Make sure hand is open
8 MOVE start ; Move to safe starting location
9 For i = 1 TO parts ; Process the parts
10 APPRO pick, height1 ; Go toward the pick-up
11 MOVES pick ; Move to the part
12 CLOSEI ; Close the hand
13 DEPARTS height1 ; Back away
14 APPRO place, height2 ; Go toward the put-down
15 MOVES place ; Move to the destination
16 OPENI ; Release the part
17 DEPARTS height2 ; Back away
18 END ; Loop for the next part
19 TYPE "ALL done.", /I3, parts, "parts processed"
20 STOP ; End of the program
21 .END

```

## Off-Line Programming and Simulation

Computer-integrated manufacturing operations require off-line programming and simulation in order to layout production facilities, model and evaluate design concepts, optimize motion of devices, avoid interference and collisions, minimize process cycle times, maximize productivity, and ensure maximum return on investment. Commercially available software (e.g., ROBCAD and SILMA [SILMA Inc., 1992]) provides support for 3D workable layouts including robots, end effectors, fixtures, conveyors, part positioners, and automatic guided vehicles. Dynamic simulation allows off-line creation, animation, and verification of robot motion programs. However, these techniques are limited to verification of overall system layout and preliminary robot program development. With support for data exchange standards (e.g., *IGES* [International Graphics Exchange Specification], *VDAPS* [Virtual Data Acquisition and File Specification], *SET* [Specification for Exchange of Text]), these software tools can pass location and trajectory data to a robot control program which, in turn, must provide the additional functions (operator guidance, logic, error recovery, sensor monitoring/control, system management, etc.) required for full operation.

## 14.7 Robot Dynamics and Control

*Frank L. Lewis*

This section deals with the real-time motion control of robot manipulators. In Section 14.8 are covered higher-level planning and control functions, including the generation of the prescribed trajectory that is assumed given in this section. Robot manipulators have complex nonlinear dynamics that might make accurate and robust control difficult. Fortunately, robots are in the class of Lagrangian dynamical systems, so that they have several extremely nice physical properties that make their control straightforward. In this section will be discussed several control techniques including computed torque (e.g., *feedback linearization*), classical joint control, digital control, *adaptive control*, *robust control*, *learning control*, *force control*, and teleoperation. More information may be found in Lewis et al. (1993). The advances that made possible this modern approach to robot control were made by Craig (1985), Slotine and Li (Slotine, 1988), Spong and Ortega (Spong and Vidyasagar, 1989), and others.

### Robot Dynamics and Properties

A robot manipulator can have either revolute joints or prismatic joints. The latter are actuators that function like an automobile antenna, extending and contracting on a linear axis. The values of the angles, for revolute joints, and link lengths, for prismatic joints, are called the link variables, and are denoted  $q_1(t)$ ,  $q_2(t)$ , ...,  $q_n(t)$  for joints one, two, and so on. The number of links is denoted  $n$ ; for complete freedom of motion in space, six degrees of freedom are needed, three for positioning and three for orientation. Thus, most commercial robots have six links. We discuss here robots which are rigid, that is which have no flexibility in the links or in the gearing of the joints; flexible robots are discussed in the section on control of flexible-link and flexible-joint robots.

The dynamics of robot manipulators with rigid links can be written as

$$M(q)\ddot{q} + V_m(q, \dot{q})\dot{q} + F(\dot{q}) + G(q) + \tau_d = \tau \quad (14.7.1)$$

where  $M(q)$  is the inertia matrix,  $V_m(q, \dot{q})$  is the coriolis/centripetal matrix,  $F(\dot{q})$  are the friction terms,  $G(q)$  is the gravity vector,  $\tau_d(t)$  represents disturbances, and  $\tau(t)$  is the control input torque. The joint variable  $q(t)$  is an  $n$ -vector containing the joint angles for revolute joints and lengths for prismatic joints. It is often convenient to write the robot dynamics as

$$M(q)\ddot{q} + N(q, \dot{q})\dot{q} + \tau_d = \tau \quad (14.7.2)$$

$$N(q, \dot{q}) \equiv V_m(q, \dot{q})\dot{q} + F(\dot{q}) + G(q) \quad (14.7.3)$$

where  $N(q, \dot{q})$  represents a vector of the nonlinear terms.

The objective of robot control is generally to select the control torques  $\tau(t)$  so that the robot follows a desired prescribed motion trajectory or exerts a desired force. Examples include spray painting, grinding, or manufacturing assembly operations. The position control objective can be achieved by first defining a desired trajectory  $q_d(t)$ , which is a vector containing the desired values vs. time  $q_{d_i}(t)$  of each of joint of the manipulator. This desired trajectory vector  $q_d(t)$  is determined in a higher-level *path planner*; based on a even higher-level task decomposition, and then fed to the real-time motion control system. This section discusses the real-time motion control problem assuming that  $q_d(t)$ , or a similar desired force vector, is given.

The robot dynamics in Equation (14.7.1) satisfies some important physical properties as a consequence of the fact that they are a Lagrangian system. These properties significantly simplify the robot control problem. The main properties of which one should be aware are the following.

### Properties of Robot Arm Dynamics

- P1 The inertia matrix  $M(q)$  is symmetric, positive definite, and bounded so that  $\mu_1 I \leq M(q) \leq \mu_2 I$  for all  $q(t)$ . For revolute joints, the only occurrences of the joint variables  $q_i$  are as  $\sin(q_i)$ ,  $\cos(q_i)$ . For arms with no prismatic joints, the bounds  $\mu_1$ ,  $\mu_2$  are constants.
- P2 The coriolis/centripetal vector  $V_m(q, \dot{q})\dot{q}$  is quadratic in  $\dot{q}$  and bounded so that  $\|V_m\dot{q}\| \leq v_B \|\dot{q}\|^2$ .
- P3 The coriolis/centripetal matrix can always be selected so that the matrix  $\dot{M}(q) - 2V_m(q, \dot{q})$  is *skew symmetric*. This is a statement of the fact that the fictitious forces in the robot system do no work.
- P4 The friction terms have the approximate form  $F(\dot{q}) = F_v\dot{q} + F_d(\dot{q})$ , with  $F_v$  a diagonal matrix of constant coefficients representing the viscous friction, and  $F_d(\cdot)$  a vector with entries like  $K_{d_i} \text{sgn}(\dot{q}_i)$ , with  $\text{sgn}(\cdot)$  the signum function, and  $K_{d_i}$  the coefficients of dynamic friction. These friction terms are bounded so that  $\|F(\dot{q})\| \leq v_B \|\dot{q}\| + k_B$  for constants  $v_B$ ,  $k_B$ .
- P5 The gravity vector is bounded so that  $\|G(q)\| \leq g_B$ . For revolute joints, the only occurrences of the joint variables  $q_i$  are as  $\sin(q_i)$ ,  $\cos(q_i)$ . For revolute joint arms the bound  $g_B$  is a constant.
- P6 The disturbances are bounded so that  $\|\tau_d(t)\| \leq d$ .
- P7 The nonlinear robot terms are *linear in the parameters* of mass and friction so that one can write

$$M(q)\ddot{q} + V_m(q, \dot{q})\dot{q} + F(\dot{q}) + G(q) = W(q, \dot{q}, \ddot{q})\phi \quad (14.7.4)$$

where  $W(q, \dot{q}, \ddot{q})$  is a matrix of known robot functions and  $\phi$  is a vector of mass and friction coefficient parameters, often unknown. The *regression matrix*  $W(\cdot)$  can be computed for any specified robot arm.

The last property, P7, is especially useful in adaptive control approaches. The bounding properties are especially useful in robust control approaches. The *skew-symmetry* property P3 is vital for Lyapunov control proofs, which provide guaranteed tracking motion and often give the structure of the control loops. It essentially allows some very nice *linear systems techniques* to be used with the time-varying robot dynamics.

### State Variable Representations and Computer Simulation

The nonlinear state-variable representation  $\dot{x} = f(x, u)$ , with  $x(t)$  the internal state and  $u(t)$  the control input, is very convenient for many applications, including the derivation of suitable control laws and computer simulation. Once the system has been put into state-space form, it can easily be integrated to obtain simulation time plots using, for instance, a Runge-Kutta integrator; many standard software packages have such integration routines, including MATLAB, MATRIX<sub>x</sub>, and SIMNON.

It is supposed for convenience in this subsection that the disturbance  $\tau_d(t)$  is equal to zero. There are three convenient state-space formulations for the robot dynamics in Equation (14.7.1). In the *position/velocity state-space form*, one defines the state as the  $2n$ -vector  $x \equiv [q^T \dot{q}^T]^T$  and writes

$$\dot{x} = \begin{bmatrix} \dot{q} \\ -M^{-1}(q)N(q, \dot{q}) \end{bmatrix} + \begin{bmatrix} 0 \\ M^{-1}(q) \end{bmatrix} u \quad (14.7.5)$$

which is in state-space form with  $u(t) \equiv \tau(t)$ .

For computer simulation purposes, the matrix inversion  $M^{-1}(q)$  is required at every integration time step. For arms with simple dynamics, it is often possible to invert the inertia matrix analytically off-line, reducing the on-line computational burden. Otherwise, it is more suitable to solve Equation (14.7.2) for  $\ddot{q}$ , required by the integration routine, using least-squares techniques to avoid the inversion of  $M(q)$ .

An alternative *linear* state-space equation in the form  $\dot{x} = Ax + Bu$  can be defined as

$$\dot{x} = \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix} x + \begin{bmatrix} 0 \\ I \end{bmatrix} u \quad (14.7.6)$$

with  $u(t) \equiv -M^{-1}(q) N(q, \dot{q}) + M^{-1}(q)\tau$ . This is known as the *Brunovsky Canonical Form*.

The third state-space formulation is the *Hamiltonian form*, which derives from Hamilton's equations of motion. Here the state is defined as the  $2n$ -vector  $x = (q^T p^T)^T$ , with  $p(t) \equiv M(q)\dot{q}$  the *generalized momentum*. Then the state-space equation is

$$\dot{x} = \begin{bmatrix} M^{-1}(q)p \\ -\frac{1}{2}(I_n \otimes p^T) \frac{\partial M^{-1}(q)}{\partial q} p \end{bmatrix} + \begin{bmatrix} 0 \\ I_n \end{bmatrix} u \tag{14.7.7}$$

with the control input defined by  $u = \tau - G(q)$  and  $\otimes$  the Kronecker product (Lewis et al., 1993).

## Cartesian Dynamics and Actuator Dynamics

### Cartesian Dynamics

The dynamics in Equation (14.7.1) are known as the *joint-space dynamics*; they are expressed in the joint-space coordinates  $q$ . Cartesian coordinates referred to some frame, often the base of the robot manipulator, may be used to describe the position of the end effector of the robot arm. Denote the Cartesian coordinates of the end of the arm as  $Y(t) = h(q)$ , whose first three coordinates represent position and last coordinates represent orientation. The nonlinear function  $h(q)$  gives the end effector Cartesian coordinates in terms of the current joint positions  $q$  and is called the *arm kinematics transformation*. The *arm Jacobian* relates joint and Cartesian velocities and is defined as  $J(q) \equiv \partial h(q)/\partial q$  so that

$$\begin{bmatrix} v \\ \omega \end{bmatrix} \equiv \dot{Y} = J(q)\dot{q} \tag{14.7.8}$$

where  $v(t)$  is the linear velocity and  $\omega(t)$  the angular velocity of the end effector. Both these velocities are 3-vectors. Differentiating this equation gives the *acceleration transformation*  $\ddot{Y} = J\ddot{q} + \dot{J}\dot{q}$ .

By differentiating Equation (14.7.1) one discovers that the dynamics may be written in Cartesian form as

$$\bar{M}\ddot{Y} + \bar{N} + f_d = F \tag{14.7.9}$$

where  $\bar{M} \equiv J^T M J^{-1}$ ,  $\bar{N} \equiv J^T(N - M J^{-1} \dot{J} J^{-1} \dot{y})$ , and the disturbance is  $f_d \equiv J^T \tau_d$ . In the Cartesian dynamics the control input is  $F$ , which has three components of force and three of torque.

The important conclusion of this discussion is that the Cartesian dynamics are of the same form as Equation (14.7.2). Furthermore, it can be shown that the properties of the robot dynamics hold also in Cartesian form. Therefore, all the control techniques to be described in this section can be used for either the joint-space or the Cartesian dynamics.

### Actuator Dynamics

The robot manipulator is driven by actuators which may be electric, hydraulic, pneumatic, and so on. Considering the case of electric motors it is direct to show that if the armature inductance is negligible, the dynamics of the arm plus actuators can be written as

$$(J_M + R^2 M)\ddot{q} + (B_M + R^2 V_m)\dot{q} + (RF_M + R^2 F) + R^2 G = RK_M v \tag{14.7.10}$$

where the robot arm dynamics are described by  $M(q)$ ,  $V_m(q, \dot{q})$ ,  $F(\dot{q})$ ,  $G(q)$ , and  $J_M$  is the motor inertia,  $B_M$  is given by the rotor damping constant and back emf, and  $R$  has diagonal elements containing the

gear ratios of the motor/joint couplings. The control input is the motor voltage  $v(t)$ , with  $K_M$  the diagonal matrix of motor torque constants.

The important conclusion is that the dynamics of the arm-plus-actuators has the same form as the dynamics (Equation (14.7.1)) and can be shown to enjoy the same properties of boundedness and linearity-in-the-parameters. Therefore, the control methods to be described herein apply to this composite system as well. Similar comments hold for other sorts of actuators such as hydraulic. If the armature inductances of the electric motors are not negligible, then the arm-plus-actuators have a coupled form of dynamics such as those discussed in the section on control of flexible-link and flexible-joint robots. Then special control techniques must be used.

## Computed-Torque (CT) Control and Feedback Linearization

For many years during the 1960s and 1970s the major techniques for robot dynamics control were based on the *computed-torque method*, which has many variants, including classical independent joint control. Recently, advanced mathematical techniques based on *feedback linearization* have been derived. For the rigid-link arms, these are equivalent.

It is assumed that the desired motion trajectory for the manipulator  $q_d(t)$ , as determined, for instance, by a path planner, is prescribed. Define the *tracking error* as

$$e(t) = q_d(t) - q(t) \quad (14.7.11)$$

and differentiate twice to see that the Brunovsky canonical form in Equation (14.7.6) can be written in terms of the state  $x = [e^T \ \dot{e}^T]^T$  as

$$\frac{d}{dt} \begin{bmatrix} e \\ \dot{e} \end{bmatrix} = \begin{bmatrix} 0 & I \\ 0 & 0 \end{bmatrix} \begin{bmatrix} e \\ \dot{e} \end{bmatrix} + \begin{bmatrix} 0 \\ I \end{bmatrix} u \quad (14.7.12)$$

with

$$u \equiv \ddot{q}_d + M^{-1}(q)(N(q, \dot{q}) - \tau) \quad (14.7.13)$$

A two-step design procedure now suggests itself. First, use linear system design techniques to select a feedback control  $u(t)$  that stabilizes the tracking error system in Equation (14.7.12), then compute the required arm torques using the inverse of Equation (14.7.13), namely,

$$\tau = M(q)(\ddot{q}_d - u) + N(q, \dot{q}) \quad (14.7.14)$$

This is a *nonlinear feedback control law* that guarantees tracking of the desired trajectory. It relies on computing the torque  $\tau$  that makes the nonlinear dynamics of Equation (14.7.1), equivalent to the linear dynamics of Equation (14.7.12), which is termed *feedback linearization*.

Selecting proportional-plus-derivative (PD) feedback for  $u(t)$  results in the *PD computed-torque controller*

$$\tau = M(q)(\ddot{q}_d + K_v \dot{e} + K_p e) + N(q, \dot{q}) \quad (14.7.15)$$

and yields the tracking error dynamics  $\ddot{e} = -K_v \dot{e} - K_p e$ , which is stable as long as the derivative gain matrix  $K_v$  and the proportional gain matrix  $K_p$  are selected positive definite. It is common to select the gain matrices diagonal, so that stability is ensured as long as all gains are selected positive.

The PD computed-torque controller is shown in Figure 14.7.1, which has a *multiloop structure*, with a nonlinear inner feedback linearization loop and an outer unity-gain tracking loop. Note that there are actually  $n$  outer loops, one for each joint. In this figure,  $\underline{q} \equiv [q^T \dot{q}^T]^T$ ,  $\underline{e} \equiv [e^T \dot{e}^T]^T$ ,  $\underline{q}_d \equiv [q_d^T \dot{q}_d^T]^T$ .

FIGURE 14.7.1 PD computed-torque controller.

To improve steady-state tracking errors,  $n$  integrators can be added, one to each joint controller, to place an integrator in the outer tracking loop in the figure. In fact, selecting  $u(t)$  as a proportional-plus-integral-plus-derivative controller yields the *PID computed-torque controller*

$$\begin{aligned} \dot{e} &= e \\ \tau &= M(q)(\ddot{q}_d + K_v \dot{e} + K_p e + K_i \varepsilon) + N(q, \dot{q}) \end{aligned} \tag{14.7.16}$$

which has its own dynamics and gives stable tracking as long as the integral gain  $K_i$  is not chosen too large.

**Example 14.7.1 (Performance of PD and PID Computed-Torque Controllers)**

The sort of performance to be expected from PD and PID CT controllers is illustrated here. It is desired for a 2-link robot arm to follow, in each of its joints, sinusoidal trajectories  $q_d(t)$  with period of 2 sec.

*Ideal PD CT Control.* Since CT is theoretically an exact cancellation of nonlinearities, under ideal circumstances the PD CT controller yields performance like that shown in Figure 14.7.2, where the initial tracking errors go to zero quickly, so that each joint perfectly tracks its prescribed trajectory. In this figure are shown the plots for joint 1 tracking error  $e_1(t)$  and joint 2 tracking error  $e_2(t)$ .

*PD CT Control with Constant Unknown Disturbance.* Now a constant unknown disturbance is added to the robot arm. As shown in Figure 14.7.3, the PD controller now exhibits steady-state tracking errors of  $e_1 = -0.01$  rad,  $e_2 = 0.035$  rad.

*PID CT Control.* If an integral term is now added to the outer loop to achieve PID CT control, even with a constant unknown disturbance, the simulation results look very much like the original plots in Figure 14.7.2; that is, the integral term has reduced the steady-state tracking errors to zero. □

A class of computed torque-like controllers is given by selecting

$$\tau = \hat{M}(\ddot{q}_d - u) + \hat{N} \tag{14.7.17}$$

where  $\hat{M}, \hat{N}$  are approximations, estimates, or simplified expressions for  $M(q), N(q, \dot{q})$ . An example is the *PD-gravity controller*

FIGURE 14.7.2 Joint tracking errors using PD computed-torque controller under ideal conditions.

FIGURE 14.7.3 Joint tracking errors using PD computed-torque controller with constant unknown disturbance.

$$\tau = K_v \dot{e} + K_p e + G(q) \tag{14.7.18}$$

which selects  $\hat{M} = I$  and only includes the gravity nonlinear terms, so that it is very easy to implement compared to full CT control. This has been used with good results in many applications.

If  $\hat{M}, \hat{N}$  are selected, not as the actual inertia matrix and nonlinear terms, but only as approximations or simplified values, it is not always possible to guarantee stable tracking. In fact, the error dynamics of Equation (14.7.12) are then driven by *modeling mismatch errors*, which can degrade or even destabilize the closed-loop system.

Another computed torque-like controller is *PID classical joint control*, where all nonlinearities of the robot arm are neglected and one selects simply

$$\begin{aligned} \dot{\varepsilon} &= e \\ \tau &= K_v \dot{\varepsilon} + K_p e + K_i \varepsilon \end{aligned} \tag{14.7.19}$$

with the gain matrices diagonal, so that all the joints are decoupled. A PD classical joint controller is shown in [Figure 14.7.4](#), which may seem familiar to many readers. The same figure may be drawn for each joint. In this figure,  $d(t)$  represents the neglected nonlinear coupling effects from the other joints, and  $r$  is the gear ratio. The motor angle is  $\theta(t)$  and  $q(t)$  is the joint angle. The effective joint inertia and damping are  $J$  and  $B$ , respectively.

**FIGURE 14.7.4** PD classical joint controller.

The simplified classical joint controller is very easy to implement, as no digital computations are needed to determine nonlinear terms. It has been found suitable in many applications if the PD gains are selected high enough, particularly when the gear ratio  $r$  is small. Unfortunately, if the gains are selected too high, the control may excite vibratory modes of the links and degrade performance. Moreover, practical applications often benefit by including additional terms such as gravity  $G(q)$ , desired acceleration feedforward  $\ddot{q}_d(t)$ , and various additional nonlinear terms.

**Example 14.7.2 (Performance of PD-Gravity and Classical Joint Controllers)**

The sort of performance to be expected from PD-gravity and classical joint controllers is shown in this example. It is desired for a 2-link robot arm to follow, in each of its joints, sinusoidal trajectories  $q_d(t)$  with period of 2 sec.

*PD-Gravity Controller.* The joint 1 and 2 tracking errors are shown in [Figure 14.7.5](#). Note that the errors are small but not exactly zero, a reflection of the fact that the nonlinear coriolis/centripetal terms are missing in the controller. However, the DC error is equal to zero, since gravity compensation is used. (The gravity terms are effectively the “DC terms” of the robot dynamics.)

*Classical PD Controller.* The sort of behavior to be expected from classical (independent joint) control is illustrated in [Figure 14.7.6](#). In this figure, the tracking errors are nonzero, but using large-enough PD gains can often make them small enough. Note that the DC error is no longer equal to zero; the offset is due to ignoring the gravity terms. □

Another important CT-like controller is the PD *digital controller* given by

$$\tau_k = M(q_k) \left( \ddot{q}_{d_k} + K_v \dot{e}_k + K_p e_k \right) + N(q_k, \dot{q}_k) \tag{14.7.20}$$

where the control input can only be computed at the *sample times*,  $t_k = KT$ , with  $T$  the sample period and  $k$  taking on integer values. Digital control is usually required in modern applications, as robot control

**FIGURE 14.7.5** Joint tracking errors using PD-gravity controller.

**FIGURE 14.7.6** Joint tracking errors using classical independent joint control.

laws are generally implemented using microprocessors or digital signal processors. Unfortunately, the stability of robot digital controllers has not been generally addressed, so that the traditional approach relies on designing continuous-time controllers, meticulously proving stability, then sampling “fast enough” and holding one’s breath.

In practice there are many other problems to be faced in robot controller implementation, including actuator saturation, antiwindup compensation, and so on. See Lewis et al., (1993).

### Example 14.7.3 (Performance of Digital CT Controllers)

The performance of digital robot controllers has several idiosyncrasies of which one should be aware. In this example, it is desired for a 2-link robot arm to follow, in each of its joints, sinusoidal trajectories  $q_d(t)$  with period of 2 sec.

*Digital CT Controller.* Using a sample period of  $T = 20$  msec yields the tracking error plots shown in Figure 14.7.7. There the performance is quite good for the specific choice of PD gains. The associated control input for joint 2 is shown in Figure 14.7.8.

FIGURE 14.7.7 Joint tracking errors using digital computed-torque controller,  $T = 20$  msec.

*Limit Cycle of Digital Robot Controller.* Unacceptable behavior in digital robot controllers can be due to integrator windup problems, selecting too large a sample period, selecting too small a sample period (so that there is not enough time to perform all control calculations in each period), or the occurrence of *limit cycles*. If the sample period is selected as  $T = 100$  msec, everything seems acceptable according to Figure 14.7.9, where the tracking errors are somewhat increased but still small. However, Figure 14.7.10 shows the control torque for link 2, which has now entered a limit cycle-type behavior due to too large a sample period. □

## Adaptive and Robust Control

Computed-torque control works very well when all the dynamical terms  $M(q)$ ,  $V_m(q, \dot{q})$ ,  $F(\dot{q})$ ,  $G(q)$  are known. In practice, robot manipulator parameters such as friction coefficients are unknown or change with time, and the masses picked up by the arm are often unknown. Moreover, computing nonlinear terms is difficult to do without exotic microprocessor-based hardware. Therefore, in applications simplified CT controllers that do not compute all nonlinear terms are used (e.g., classical joint control). These methods rely on increasing the PD gains to obtain good performance. However, large control signals may result and stability proofs of such controllers are few and far between. Adaptive and robust control techniques are useful in such situations to improve upon the performance of basic PD control

**FIGURE 14.7.8** Joint 2 control torque using digital computed-torque controller,  $T = 20$  msec.

**FIGURE 14.7.9** Joint tracking errors using digital computed-torque controller,  $T = 100$  msec.

techniques, providing good performance that can be mathematically proven and so relied upon in applications. Such advanced techniques also extend directly to more complicated control objectives such as force control for grinding, polishing, and so on where straight PD methods are inadequate.

There are many sorts of adaptive and robust controllers (Lewis et al., 1993). A unifying design technique is presented here that extends as well to intelligent control using neural network and fuzzy

**FIGURE 14.7.10** Joint 2 control torque using digital computed-torque controller,  $T = 100$  msec.

logic techniques. Thus, given the desired trajectory  $q_d(t)$ , define the tracking error and *filtered tracking error*  $r(t)$  by

$$e = q_d - q \tag{14.7.21a}$$

$$r = \dot{e} + \Lambda e \tag{14.7.21b}$$

with  $\Lambda$  a positive definite design parameter matrix. Common usage is to select  $\Lambda$  diagonal with large positive entries. Then Equation (14.7.21b) is a stable system so that  $e(t)$  is bounded as long as the controller guarantees that the filtered error  $r(t)$  is bounded.

Differentiating Equation (14.7.21b) and invoking Equation (14.7.1), it is seen that the robot dynamics are expressed in terms of the filtered error as

$$M\dot{r} = -V_m r + f(x) + \tau_d - \tau \tag{14.7.22}$$

where the *nonlinear robot function* is defined as

$$f(x) + M(q)(\ddot{q}_d + \Lambda\dot{e}) + V_m(q, \dot{q})(\dot{q}_d + \Lambda e) + F(\dot{q}) + G(q) \tag{14.7.23}$$

Vector  $x$  contains all the time signals needed to compute  $f(\cdot)$  and may be defined, for instance, as  $x \equiv [e^T \ \dot{e}^T \ q_d^T \ \dot{q}_d^T \ \ddot{q}_d^T]^T$ . It is important to note that  $f(x)$  contains all the potentially unknown robot arm parameters, except for the  $V_m r$  term in Equation (14.7.22), which cancels out in the proofs.

A general sort of controller is now derived by setting

$$\tau = \hat{f} + K_v r - v(t) \tag{14.7.24}$$

with  $\hat{f}$  an *estimate* of  $f(x)$ ,  $K_v r = K_v \dot{e} + K_v \Lambda e$  an *outer PD tracking loop*, and  $v(t)$  an auxiliary signal to provide robustness in the face of disturbances and modeling errors. The estimate  $\hat{f}$  and robustifying

FIGURE 14.7.11 Adaptive filtered error controller.

signal  $v(t)$  are defined differently for adaptive control, robust control, neural net control, *fuzzy logic control*, etc. The multiloop control structure implied by this scheme is shown in Figure 14.7.11.

### Adaptive Controller

Using nonlinear stability proofs based on Lyapunov or passivity techniques, it can be shown that tracking error stability can be guaranteed by selecting one of a variety of specific controllers. One such is the adaptive controller shown in Figure 14.7.11 and described by the equations

$$\begin{aligned} \tau &= W(w)\hat{\phi} + K_v r \\ \hat{\phi} &= \Gamma W^T(w)r \end{aligned} \tag{14.7.25}$$

where  $\Gamma$  is a tuning parameter matrix, generally selected diagonal with positive elements. Matrix  $W(x)$  is the (known) regression matrix chosen such that  $f(x) = W(x)\phi$ , with all the unknown parameters placed into the vector  $\phi$ ;  $W(x)$  must be computed off-line in a design phase for the specific robot arm to be controlled (Lewis et al., 1993). In the adaptive controller, the second equation represents the internal dynamics of the controller, where the estimate  $\hat{\phi}$  of the unknown parameter vector is produced by dynamic on-line tuning. The robot control input  $\tau(t)$  is then given in terms of  $\hat{\phi}$  by the first equation. Though it need not be computed to produce the control inputs, the estimate of the nonlinear function is given by  $\hat{f}(x) = W^T(x)\hat{\phi}$ .

The adaptive controller shown in Figure 14.7.11 has a multiloop structure with an outer PD tracking loop and an inner nonlinear adaptive loop whose function is to estimate the nonlinear function required for feedback linearization of the robot arm.

### Robust Saturation Controller

Another filtered error controller is the robust saturation controller

$$\begin{aligned} \tau &= \hat{f} + K_v r - v \\ v &= \begin{cases} -r \frac{F(x)}{\|r\|}, & \|r\| \geq \epsilon \\ -r \frac{F(x)}{\epsilon}, & \|r\| < \epsilon \end{cases} \end{aligned} \tag{14.7.26}$$

where  $\hat{f}$  is an estimate for  $f(x)$  that is not changed on-line — for instance, a PD-gravity-based robust controller would use  $\hat{f} = G(q)$ , ignoring the other nonlinear terms. In computing the robust control term  $v(t)$ ,  $\epsilon$  is a small design parameter,  $\|\cdot\|$  denotes the norm, and  $F(x)$  is a known function that bounds the uncertainties  $\|f - \hat{f}\|$ . The intent is that  $F(x)$  is a simplified function that can be computed even if the exact value of the complicated nonlinear function  $f(x)$  is unknown.

**Variable Structure Robust Controller**

Another robust controller is the *variable structure robust controller*

$$\begin{aligned} \tau &= \hat{f} + K_v r - v \\ v &= -(F(x) + \eta) \text{sgn}(r) \end{aligned} \tag{14.7.27}$$

where  $\text{sgn}(\cdot)$  is the signum function and  $F(x)$  is a known function computed to bound the uncertainties  $\|f - \hat{f}\|$ . The design parameter  $\eta$  is selected as a small value. This controller takes advantage of the properties of sliding mode or variable structure controllers to provide its robustness.

In adaptive controllers the primary design effort goes into selecting a dynamic estimate  $\hat{f}$  that is tuned on-line. By contrast, in robust controllers, the primary design effort goes into selecting the robust term  $v(t)$ . An advantage of robust controllers is that they have no dynamics, so they are generally simpler to implement. On the other hand, adaptive controllers are somewhat more refined in that the dynamics are learned on-line and less control effort is usually needed. Furthermore, in adaptive control it is necessary to compute the regression matrix  $W(x)$ , while in robust control it is necessary to compute the bounding function  $F(x)$ .

**Example 14.7.4 (Performance of Adaptive and Robust Robot Controllers)**

This example illustrates the sort of performance to be expected from adaptive and robust controllers. In this example, it is desired for a 2-link robot arm to follow, in each of its joints, sinusoidal trajectories  $q_d(t)$  with period of 2 sec.

*Adaptive Control.* In adaptive control, the controller dynamics allow for learning of the unknown parameters, so that the performance improves over time. Typical plots are like those in Figure 14.7.12, where the errors start out large but then converge to zero, and the parameter (mass) estimates converge to constant values.

**FIGURE 14.7.12** Typical behavior of adaptive controller.

**Robust Control.** In typical robust controllers, there are no controller dynamics so that the performance does not improve with time. However, with good designs (and large-enough control gains) the errors are bounded so that they are small enough. Typical plots are like those in Figure 14.7.13, where the errors are always small, though nonzero, but do not become smaller with time.  $\square$

FIGURE 14.7.13 Typical behavior of robust controller.

## Learning Control

In many industrial applications robot manipulators are used to perform the same task repeatedly, such as in spray painting, short assembly operations, component insertion, and so on. In such repetitive motion situations, information from one iteration can be recorded and used to improve the performance on the next iteration. This is termed repetitive motion learning control. Using the filtered error approach of the section on adaptive and robust control, it is direct to derive the learning controller of Sadegh et al. for the robot arm in Equation (14.7.1).

Let  $\ell = 1, 2, \dots$  denote the iteration number of the trajectory repetition. Then, using information from the  $(\ell - 1)$ st iteration, the controller for the  $\ell$ th iteration is given by

$$\begin{aligned}\tau_\ell &= \hat{f}_\ell + K_v r - v \\ v &= -\left(K_p e + K_s \|e\|^2 r\right) \\ \hat{f}_\ell &= \hat{f}_{\ell-1} + K_L r\end{aligned}\tag{14.7.28}$$

where the filtered error is  $r = \dot{e} + \Lambda e$ ,  $e = q_d - q$ , with  $q_d(t)$  the specified trajectory to be followed repeatedly. The gains  $K_v$ ,  $K_p$ ,  $K_s$  are positive diagonal design matrices, and  $K_L$  is a positive diagonal learning gain matrix. The function  $\hat{f}_\ell$  is a learning term that uses its value on the previous iteration to improve on an estimate for a nonlinear function appearing in the error analysis.

## Control of Flexible-Link and Flexible-Joint Robots

If the robot arm has flexible links, flexible joints, or fast motor dynamics, the control schemes just discussed must be modified. There are two basic cases to consider: *flexible-link robots* and flexible-joint robots; fast motor dynamics can be considered a special case of the latter.

### Flexible-Link Robots

In the case of flexible-link robots, the links have significant vibratory modes that cannot be neglected. In this case one may perform an analysis using, for instance, the Bernoulli-Euler model, obtaining an infinite dimensional (partial differential equation) model, which can then be truncated to a finite dimensional (ordinary differential equation) model using, for instance, assumed mode shape techniques. The result is a model such as

$$\begin{aligned} M_{rr}\ddot{q}_r + M_{rf}\ddot{q}_f + V_{rr}\dot{q}_r + V_{rf}\dot{q}_f + F_r(\dot{q}_r) + G_r(q_r) &= B_r\tau \\ M_{fr}\ddot{q}_r + M_{ff}\ddot{q}_f + V_{fr}\dot{q}_r + V_{ff}\dot{q}_f + K_{ff}q_f &= B_f\tau \end{aligned} \tag{14.7.29}$$

which describes the coupling between the rigid modes  $q_r(t)$  and the flexible modes  $q_f(t)$ . In these equations, the quantities  $M, V, F, G$  are defined basically as in Equation (14.7.1) and  $K_{ff}$  is a matrix of flexible mode stiffness constants.

The complete dynamics are now described by the vector  $q = [q_r^T \ q_f^T]^T$ . The control objective is to control the link-tip positions to follow a desired trajectory  $q_d(t)$  while making small the flexible modes  $q_f$ . In the pinned-pinned modes shape method, for instance, the link-tip positions are given by  $q_r(t)$ . The major problem is that there are now *more degrees of freedom in  $q(t)$  than control inputs available in  $\tau$* . This complicates the control problem greatly; however, a key property is that the matrix  $B_r$  is *nonsingular* in flexible-link manipulators.

It can be shown by using a singular perturbation approach, followed by the filtered error approach of the section on adaptive and robust control, that all the basic controllers just described can be used for flexible-link arms if an *additional inner control loop* is added for vibration management. That is, to the control torque  $\tau(t)$  generated by Equation (14.7.24), is added the boundary-layer correction (fast) control term, manufactured by an inner loop, given by

$$u_F = -\frac{K_p}{\epsilon^2}q_f - \frac{K_d}{\epsilon}\dot{q}_f + \frac{K_p}{\epsilon^2}\bar{q}_f \tag{14.7.30}$$

where  $\epsilon$  is a small parameter (determined according to the time-scale separation imposed by the elements of the stiffness matrix  $K_{ff}$ ). The slow manifold term  $\bar{q}_f$  is a function of the slow control  $\bar{u}$  (which is found as before), the variable  $q(t)$ , and some system parameters. It is possible to avoid measurements of the flexible mode rates  $\dot{q}_f$ .

### Flexible-Joint Robots

The case of flexible-joint robots is in some ways the “dual” problem to that of flexible links. The dynamics of a robot arm driven by motors through rigid joints are given by Equation (14.7.10) for which the controllers described in previous subsections can be used. The dynamics of a robot arm driven by motors through joints with flexibility that is not negligible are given by

$$\begin{aligned} M\ddot{q}_r + V_m\dot{q}_r + F_r(\dot{q}_r) + G_r(q_r) &= K_J(q_f - q_r) \\ J_M\ddot{q}_f + B_M\dot{q}_f + F_M(\dot{q}_f) + K_J(q_f - q_r) &= v \end{aligned} \tag{14.7.31}$$

where  $q_r(t)$  is the robot joint variable vector,  $q_f(t)$  are the motor angles, and quantities are defined as per the discussions on Equations (14.7.1) and (14.7.10). It is assumed for simplicity that the gear ratio is  $R = 1$ . The stiffnesses of the joint motor couplings are on the diagonals of the joint stiffness matrix  $K_j$ .

The flexible-joint controller problem can be confronted using either a singular perturbation approach (work by M. Spong) or a *backstepping* approach. Using backstepping, it is found that the same basic structure of controller can be used as in Figure 14.7.30, but now the controller has multiple loops, with two adaptive systems required. The extra loop arises since the control input  $v(t)$  controls directly the motor angles, which provide indirectly an input into the arm dynamics to control  $q_r(t)$ , the quantity of actual interest.

## Force Control

In many industrial applications it is desired for the robot to exert a prescribed force normal to a given surface while following a prescribed motion trajectory tangential to the surface. This is the case in surface finishing etc. A hybrid position/force controller can be designed by extension of the principles just presented.

The robot dynamics with environmental contact can be described by

$$M(q)\ddot{q} + V_m(q, \dot{q})\dot{q} + F(\dot{q}) + G(q) + \tau_d = \tau + J^T(q)\lambda \quad (14.7.32)$$

where  $J(q)$  is a Jacobian matrix associated with the contact surface geometry and  $\lambda$  (the so-called ‘‘Lagrange multiplier’’) is a vector of contact forces exerted normal to the surface, described in coordinates relative to the surface.

The prescribed surface can be described by the geometric equation  $\phi(y) = 0$ , with  $y = h(q)$  the Cartesian position of the end of the arm and  $h(q)$  the kinematics transformation. The constraint Jacobian matrix  $J(q) \equiv \partial\{\phi[h(q)]\}/\partial q$  describes the joint velocities when the arm moves on the surface; in fact, the normal velocity is  $J(q)\dot{q} = 0$ . According to the implicit function theorem, on the surface  $\phi(q) = 0$  one may find a function  $\gamma(\cdot)$  that  $q_2 = \gamma(q_1)$ , where the reduced variable  $q_1(t)$  corresponds to motion in the plane of the surface and  $q_2(t)$  represents dependent variables. The robot, constrained for motion along the surface, satisfies a *reduced-order* dynamics in terms of  $q_1(t)$ . Defining the extended Jacobian  $L(q_1) \equiv [I^T \partial\gamma^T/\partial q_1]^T$ , the relation of  $q_1$  to the full joint variable  $q$  is given via  $\dot{q} = L(q_1)\dot{q}_1$ . For further details see McClamroch and Wang (1988) and Lewis et al. (1993).

The hybrid position/force control problem is to follow a prescribed motion trajectory  $q_{1,d}(t)$  tangential to the surface while exerting a prescribed contact force  $\lambda_{v,d}(t)$  normal to the surface.

Define the filtered motion error  $r_m = \dot{e}_m + \Lambda e_m$ , where  $e_m = q_{1,d} - q_1$  represents the motion error in the plane of the surface and  $\Lambda$  is a positive diagonal design matrix. Define the force error as  $\tilde{\lambda} = \lambda_{v,d} - \lambda$ , where  $\lambda(t)$  is the normal force measured in a coordinate frame attached to the surface. Then a hybrid position/force controller has the structure

$$\tau = \hat{f} + K_v L(q_1) r_m + J^T [\lambda_{v,d} + K_f \tilde{\lambda}] - v \quad (14.7.33)$$

This controller has the basic structure of Figure 14.7.11, but with an inner force control loop. In this controller, the nonlinear function estimate inner loop  $\hat{f}$  and the robustifying term  $v(t)$  can be selected using any of the techniques mentioned heretofore, including adaptive control, robust control, intelligent control, and so on. A simplified controller that may work in some applications is obtained by setting  $\hat{f} = 0$ ,  $v = 0$ , and increasing the PD motion gain  $K_v$  and force gain  $K_f$ .

## Teleoperation

In teleoperation, a human operator conducts a task, moving a master robot manipulator and thus defining motion and force commands. The master is connected through a communication channel to a slave robot manipulator in a remote location whose purpose is to mimic the master, thus performing the commanded motions and exerting the commanded forces on its environment. A typical teleoperation system is depicted in Figure 14.7.14. Task performance is enhanced if the human operator has information on the contact force being exerted by the slave manipulator. A convenient way of providing this information is to “reflect” the contact force to the motors on the master so the operator can feel a resistive force indicative of the contact force.

FIGURE 14.7.14 Typical robotic teleoperation system.

To focus on the issues peculiar to teleoperation, one can consider simplified dynamics for the master and slave arms given, respectively, by

$$M_m \dot{v}_m = F_h + \tau_m \tag{14.7.34}$$

$$M_s \dot{v}_s = -F_e + \tau_s \tag{14.7.35}$$

where the human operator input torque is  $F_h$  and the contact force exerted by the slave is  $F_e$ . In actual systems, one should include the nonlinear coriolis, centripetal, friction, and gravity terms (see Equation (14.7.1)), so that a preliminary feedback linearization (computed torque control) is needed to get the dynamics in this simplified form. Moreover, the Jacobians associated with the force inputs should also be considered (see Equation (14.7.32)).

The control problem is to provide motor control torques  $\tau_m, \tau_s$  so that the slave velocity  $v_s = \dot{q}_s$  equals the commanded (master) velocity  $v_m = \dot{q}_m$  and the environmental contact force  $F_e$  is proportional to the commanded force  $F_h$  (there could be a desired force amplification). In Figure 14.7.14,  $F_s$  is the sensed force resulting from the contact force  $F_e$ , the reflected force provided to the master robot is  $F_{md}$ , and  $v_{sd}$  is the desired velocity command for the slave. A straightforward control scheme for teleoperation is given by

$$\begin{aligned} \tau_m &= -K_m v_m - F_{md} \\ \tau_s &= -K_s v_s + F_s - \alpha_f F_e \end{aligned} \tag{14.7.36}$$

where  $K_m, K_s$  are positive master and slave control gains and  $\alpha_f$  is a positive force gain. The selection of  $\tau_s$  closes a local force control loop around the slave manipulator.

The key to successful control now lies in the appropriate definition of  $F_s, F_{md}$ , and  $v_{sd}$ . A naive definition of the sensed force is  $F_s = F_e$ , the contact force. It has been observed in experiments that this definition is unsuitable and results in instability. Therefore, a *coordinating torque*  $F_s$  is defined based on the slave velocity error  $e_s(t) \equiv v_{sd}(t) - v_s(t)$  so that

$$\begin{aligned} \dot{e}_s &= v_{sd} - v_s \\ F_s &= K_p e_s + K_i \varepsilon \end{aligned} \tag{14.7.37}$$

Though it may seem odd to define  $F_s$  in terms of the velocity error, it can be shown that, taking into account the impedance relationship of the environment,  $F_e = Z_e v_s$ , this definition makes the coordinating torque dependent on the contact force  $F_e$ . In fact, this definition results in the *passivity* of the slave dynamics referred to the variables  $(v_s, F_s)$ .

Now, it can be shown that stable teleoperation results if one selects

$$\begin{aligned} F_{md} &= F_s \\ v_{sd} &= v_m \end{aligned} \tag{14.7.38}$$

Unfortunately, if there is any delay in the communications channel, this simple scheme is doomed to failure and results in unstable control. One technique for repairing this problem is to remove the force reflection and let the operator rely on transmitted visual information to infer the contact forces. In practical applications, this can result in the exertion of excessive forces that break tools and fixtures.

It has been shown in Anderson and Spong (1989) that if there is a time delay  $T$  in the communications channel, one may modify the controller as shown in Figure 14.7.15 to obtain stable teleoperation regardless of the magnitude of  $T$ . In this figure  $N$  is a positive scaling factor introduced since the force and velocity signals may differ by orders of magnitude. This modification makes all blocks in the diagram *strictly passive*, so that stability can be shown using circuit analysis techniques. The teleoperation controller with time delay compensation is given by the torques Equation (14.7.36), the coordinating torque in Equation (14.7.37), and the modified reflected force and slave velocity commands given by

**FIGURE 14.7.15** Passive robotic teleoperation system using active control.

$$\begin{aligned} F_{md}(t) &= F_s(t-T) + n^2[v_m(t) - v_{sd}(t-T)] \\ v_{sd}(t) &= v_m(t-T) + \frac{1}{n^2}[F_{md}(t-T) - F_s(t)] \end{aligned} \tag{14.7.39}$$

It is noted that in this modified controller, part of the reflected force is derived from the slave velocity error and part of the slave velocity command is derived from a force error term.

## 14.8 Planning and Intelligent Control

---

*Chen Zhou*

The previous section dealt with servo-level joint control of robot manipulators. This section deals with higher-level functions of planning and control, including generation of the prescribed joint trajectories that are required for servo-level control. Robots are designed to accomplish various tasks such as spot welding in assembly, part loading in material handling, or deburring in processing. A task consists of a series of complex motions of various joints and the end effector. The execution of robot tasks is controlled by robot programs. Robot programming can be classified into three levels: (1) joint level, (2) manipulator level, and (3) task level (see Leu, 1985). At the joint and manipulator levels, a task is decomposed into a set of explicit paths. The robot program is essentially a series of move statements to instruct the robot to pass through a sequence of paths. The programming at these two levels involves tedious specification of points, paths, and motions.

The difficulties involved at the first two levels of programming led to research and development for task level programming. At the task level, a robot program is a sequence of goals or objective states of the tasks, such as inserting a peg or deburring an edge. Due to the omission of explicit path and kinematic instructions by the programmer, the robot must know its configurations, its environment and the goal locations, such as the location of materials, as well as the obstacles within the envelope. The robot controller has to construct a set of collision-free paths that are optimized in terms of time, motion, or other control characteristics.

Task planning is a process in which the detailed motion control involved in a task (or a subtask) is determined by software or algorithms. The objectives can include proper grasp configurations, collision-free paths, minimum travel distance, minimum travel time, and avoidance of *singularities*. In a singular configuration, the robot may lose a degree of freedom or lose the ability to provide designed power. For complex tasks, task decomposition can be performed to provide more specific control of the robot. *Path planning* is a process of finding a continuous path from an initial robot configuration to a goal configuration without collision. It is a very important component in task planning.

Task planning includes several special cases. First, errors can occur during execution of a task. Various sensors have been developed to detect error conditions. Since the occurrence of an error is random, there is uncertainty associated with task planning when error and error recovery are concerned. Second, multiple robots are often used in robotic applications. The simplest case involves two arms. An important issue in two-arm task planning and control is the coordination of the two arms. Third, in robotic manufacturing cells, robots must coordinate with other equipment in the cell and the control of the robot can often affect the performance of the entire cell. Therefore, cell control is also discussed in this section. At the end of this section, we also mention artificial intelligence as applied to planning and man-machine interface.

### Path Planning

Path planning involves finding a continuous path from an initial robot configuration  $C_{\text{init}}$  to a goal configuration  $C_{\text{goal}}$  without collision. [Figure 14.8.1](#) illustrates an example of path planning in two-dimensional space. The small rectangular object represents a *mobile robot* or an end effector of a manipulator, and the other objects represent the obstacles within the working envelope. The dashed line shows the path of the center point of the robot. The four small rectangles show the orientation of the robot at the initial, goal, and two intermediate configurations.

Often, the collision-free path is not unique. In addition to avoiding collision, one can also add requirements for smoother motion, shorter traveling distance, shorter traveling time, or more clearance from the obstacles. Therefore, path planning can also involve optimization with respect to certain performance measures.

**FIGURE 14.8.1** Illustration of path-planning problem.

The abstract model of the path-planning problem can take different forms depending on the application characteristics. It can be in two dimensions or in three dimensions. The concern can be the end effector alone or the entire robot arm. The end effector can be considered as a solid body or an infinitesimal point. Different considerations can have significant implications on the solution methodology and complexity. In this handbook, we will only discuss the simplest cases in which a point end effector in two-dimensional space is concerned. The readers are referred to Latombe (1991) for more complex procedures.

### Road Map Approach Based on Visibility Graph

The road map approach is one of the earliest path-planning methods. The obstacles are modeled as polygons. A *visibility graph* is a nondirected graph. The nodes of the graph are the vertices of the polygons, the initial point and the goal point. The links of the graphs are straight-line segments that connect a pair of nodes without intersecting with any obstacles. A reduced visibility graph for the example is shown in Figure 14.8.2. A reduced visibility graph does not contain links that are dominated by other links in terms of distance. The elliptical obstacle is approximated by a hexagon. In the visibility graph, all the paths consisting of successive links that connect  $C_{init}$  to  $C_{goal}$  represent semicollision-free paths. The coarse line represents one of these paths. The use of the term “semicollision free” is due to the fact the path may actually contact an obstacle. It is clear that the path is not unique. In the example the possible paths can be  $C_{init}AC_{goal}$ ,  $C_{init}BC_{goal}$ , or  $C_{init}CD_{goal}$ . Some offer shorter travel distances while others offer smoother paths. This method can be extended to include circular end effector and obstacles which have lines and arcs as boundaries.

### Road Map Approach Based on Voronoi Diagram

For the same problem described above, one can create a *Voronoi diagram* based on the vertices and line segments of the obstacles and the working envelope and use this graph to generate a collision-free path. A Voronoi diagram is a diagram that consists of lines having equal distance from the adjacent objects. Obviously, the Voronoi diagram does not touch the obstacles and can provide collision-free paths. A Voronoi diagram in a polygonal space with polygonal obstacles is composed of straight line segments and parabolas. When both adjacent object segments are straight lines or vertices, the segment of the Voronoi diagram is a straight line. When one object segment is a point while the other is a line segment, the segment of Voronoi diagram is a parabola. Two additional links need to be created to connect the  $C_{init}$  and  $C_{goal}$  to the Voronoi diagram. Any set of links that connects  $C_{init}$  and  $C_{goal}$  through the diagram represents a collision-free path. Unlike the road map approach based on visibility graph, this approach tends to maximize the clearance between the robot and the obstacles. For the characteristics and creation of the Voronoi diagrams, the reader is referred to Okabe et al. (1992).

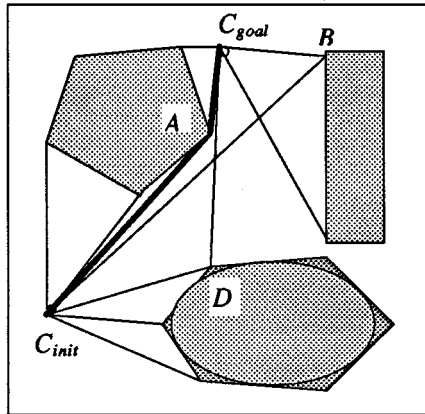

FIGURE 14.8.2 Road map method based on visibility graph.

**Cell Decomposition Approach**

In the *cell decomposition* approach, the robot free space is decomposed into simple connected geometric shapes, or cells such that a path can be generated between any two points within a cell. When Euclidean distance is used (as when using a Cartesian robot), convex polygonal cells satisfy this requirement. The simplest way to generate cells is the line sweeping method. An example in which the work envelope and the obstacles are polygons is shown in Figure 14.8.3. The two shaded areas are obstacles. In this example, the decomposition is done by sweeping a vertical line across the work envelope. A cell is formed whenever a vertex is encountered by the sweeping line. After decomposition, a *connectivity graph* is constructed. A connectivity graph is a nondirected graph. The nodes of the graph are the cells. If two cells share a common edge, they are connected and a link is drawn between the two nodes. The existence of a collision-free path can be found by searching the connectivity graph to see if there exists a path that connects two nodes containing  $C_{init}$  and  $C_{goal}$ . If such a path exists, one can construct collision-free paths by determining paths in the cells and connect the paths in adjacent cells.

Apparently, the path and decomposition are not unique. One can select different paths and decompositions to optimize other measures. Figure 14.8.3(d) shows another possible decomposition of the same space.

**Potential Field Approach**

The idea of the *potential field* method is to represent the robot work space as a potential field which has peaks and a valley. The valley is at the goal configuration, while the peaks are at the location of the obstacles. The robot, represented by an article, will roll naturally away from the peaks and toward the valley in such a terrain. Mathematically, this is done by creating an artificial potential field with peaks as obstacles and a valley as the goal, and by using a search procedure to plan a descending path to the valley. The artificial potential field is composed of an attractive potential with its lowest point as the goal configuration, and a repulsive potential for each of the obstacles. An example is shown in Figure 14.8.4. The dimension of the robot envelope is 10 wide and 10 high. Here  $ZG$  is the attractive potential function,  $ZR$  is the repulsive potential function for all obstacles, and  $Z$  is the combined potential function. In this example, the attractive potential function  $ZG$  is a parabolic well:

$$ZG(x,y) = \frac{A}{2} \left[ (x - G_x)^2 + (y - G_y)^2 \right] \tag{14.8.1}$$

where  $A$  is a constant used to adjust the magnitude of the attractive field,  $G_x = 2$  and  $G_y = 1$  are the coordinates of  $C_{goal}$ .  $ZR$  represents three cylindrical obstacles with diameters 2, 1, and 1, respectively.

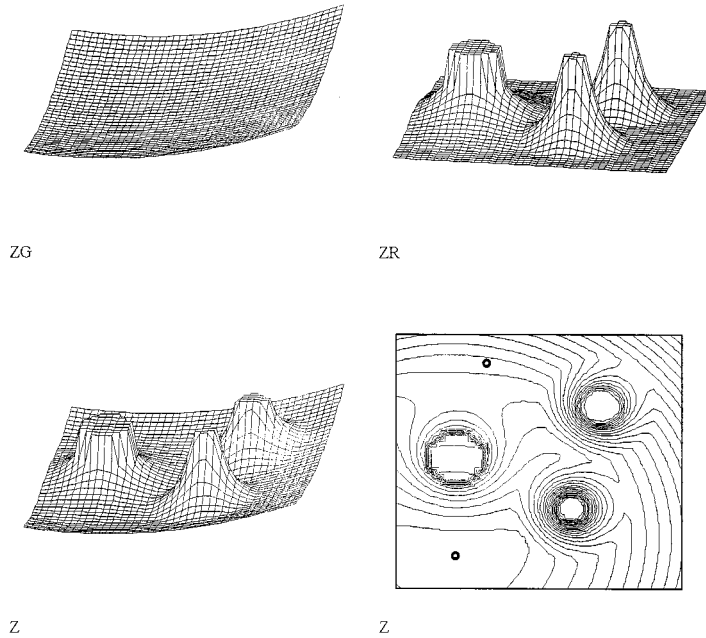

**FIGURE 14.8.3** Cell decomposition method.

The center location of the three obstacles are at  $(2, 5)$ ,  $(7, 7)$ , and  $(6, 3)$ . Let  $ZR_i$  be the obstacle repulsive fields of  $i^{th}$  cylindrical obstacle. The repulsive function for  $i^{th}$  obstacle is

$$ZR_i(x, y) = \begin{cases} \frac{B_i}{2} \left[ \frac{1}{\sqrt{(x - R_{x,i})^2 + (y - R_{y,i})^2}} - C_i \right] & \text{if } \frac{D_i}{2} \geq \sqrt{(x - R_{x,i})^2 + (y - R_{y,i})^2} < D_i \\ Z_i & \text{if } \sqrt{(x - R_{x,i})^2 + (y - R_{y,i})^2} \leq \frac{D_i}{2} \\ 0 & \text{otherwise} \end{cases} \quad (14.8.2)$$

where  $B_i$  is a constant for the adjustment of the height of  $i^{th}$  peak,  $D_i$  is the diameter of the  $i^{th}$  cylindrical obstacle, and  $R_{x,i}$  and  $R_{y,i}$  are the center coordinates of the cylinder. The characteristic of this function

**FIGURE 14.8.4** Potential field method example.

is that the potential at any point with distance more than twice the diameter of the closest obstacle is zero. Also, the potential inside the obstacle is a constant and equal to the potential at the boundary of the obstacle, where  $C_i$  is a constant to accomplish the former and the  $Z_i$  is a constant for the latter. The total potential is the sum of all the terms:

$$Z = ZG + \sum_{i=1}^3 ZR_i \tag{14.8.3}$$

There are several techniques for potential guided path planning. The simplest is the depth first planning. In depth first planning, a prespecified step  $\delta$  is predefined. The path will be found iteratively using

$$\begin{aligned} x_{n+1} &= x_n + \delta \frac{\partial Z(x_n, y_n)}{\partial x} \\ y_{n+1} &= y_n + \delta \frac{\partial Z(x_n, y_n)}{\partial y} \end{aligned} \tag{14.8.4}$$

where  $x_0$  and  $y_0$  are at  $C_{init}$ . Depth first planning is very fast for certain situations but may cause trapping some local point in others.

### Error Detection and Recovery

In the execution of a task, errors can occur. The errors can be classified into several categories: hardware error, software error, and operational error. The hardware errors include errors in mechanical and electrical mechanisms of the robot, such as failure in the drive system or sensing system. Software errors can be bugs in the application program or control software. Timing with cooperative devices can also

be called software error. The operational errors are the errors in the robot environment that are external to the robot system such as jamming of parts or collision with obstacles.

The sensors used in error detection can be classified into several categories: tactile sensors for sensing contact and existence, proximity sensors for sensing location or possible collision, force/torque sensors for sensing collision and jamming, and vision for sensing location, orientation, and existence.

The occurrence of an error normally causes interruption of the normal task execution. Error recovery can be done at three levels. At the lowest level, the task is not resumable. Upon detection of an error, the task is interrupted automatically. The error must be corrected manually and the task must start again manually. At the second level, the task can be resumed. Upon detection of an error, the error can be corrected manually and the task can be continued from the point where the error occurred. At the third level, upon detection of an error, the error will be corrected automatically and the task execution is continued. [Figure 14.8.5](#) shows an example of error and recovery in an insertion task.

**FIGURE 14.8.5** Jamming error detection and recovery.

In this insertion example, a peg is misaligned with the hole. The misalignment can be caused by wrong location of the fixture, wrong positioning of the peg before pickup, etc. The jamming error can be detected by a vertical force sensor in the gripper. At the lowest level, this can be used to trigger an emergency stop and an alarm. An operator can withdraw the gripper, remove the peg, and start the cycle again. At the second level, the operator can correct the problem and continue the insertion after the error condition is corrected. At the third level, additional sensory information is required. For example, additional force sensors can be used to identify the jamming torque. The torque information can be used to redirect the end effector to put the peg in the hole correctly. Since the occurrence of error is random in nature, the incorporation of error recovery introduces uncertainty into task planning. Artificial intelligence methods are often employed in error recovery.

## Two-Arm Coordination

Many robotic applications require multiple arms, such as lifting heavy weights in handling or assembling two components that require simultaneous motion. In such applications, a special planning and control issue is the coordination of two arms. [Figure 14.8.6](#) shows an example of two-arm application. In two-arm applications, two arms form a closed chain. Each arm acts as a constraint on the other and can have different contributions to the motion of the part. In terms of constraints, one or both arms can have rigid grasps. Two arms may also be controlled to remain in contact at a point, along a line, or on a surface. In terms of control, two-arm coordination can rely on a master/slave relationship, a push/pull relationship, or other relationships. In the master/slave relationship, one arm is controlled in force mode (master) while the other is controlled in position mode (slave). These constraints and control relationships require different controls from both controllers. Please see Hayati et al. (1989) for more discussion.

**FIGURE 14.8.6** Two-arm coordination.

## Workcell Control

Robots are used in many workcells for machine loading/unloading, assembly, part *kitting*, packaging, etc. The task planning associated with workcell control has its unique characteristics. A robot in a workcell often interacts with other resources in the cell such as a machine, a conveyor, a fixture, or a container. These interactions often require exact coordination. The coordination is done based on the clocks or interlocks implemented through *discrete inputs* (DI) and *discrete outputs* (DO). A DO is a binary signal that can be set in one of the two states and a DI is a binary sensing that can detect one of the two possible states from a DO.

In a flexible robotic manufacturing cell, alternative actions often exist for robot control, such as which assembly task to perform first, or which machine to serve first. The ordering of these different alternatives can directly affect the utilization, throughput, and other measures of the cell. Due to its discrete nature, the cell control optimization problem is combinatorial in nature and expands rapidly with problem size. As a result, dispatching rules in scheduling are often employed as rules in rule-based cell controllers.

Additional concerns in cell control relate to two commonly used terms in production system control: *blocking* and *deadlock* (or *locking*). Blocking is a condition in which material cannot be transported to its next location because of a temporary resource unavailability. This can cause the waste of capacity of the current machine. Deadlock is a condition in which two resources mutually require the service of the other but neither can provide the required service at the current state. Therefore, the system will be deadlocked. Examples of blocking and locking are given in [Figure 14.8.7](#).

**FIGURE 14.8.7** Example of blocking and locking.

In the figure on the left, the part on M1 needs to be transported to M2. However, M2 is in processing state and therefore the part in M1 has to wait for its completion. In the figure on the right, both parts on M1 and M2 are finished and need to be transported to the other machine. Suppose the robot has a single end effector; it is not able to transport either part to the other machine. One possible solution to blocking and deadlock problems is to add buffers. In the example, if a buffer location is added to the cell, the blocking and deadlock can be temporarily resolved. However, the addition of buffers to a cell can increase the cost of the cell and the complexity of the control. The real-time solution to blocking and deadlock problems lies in the identification of possible blocking or deadlocks and prevents them from occurring. Blocking or deadlock avoidance and system optimization are combinatorial in nature. The number of states expands exponentially with the number of states for each resource and number of part types. Therefore, rule-based systems and AI techniques find wide acceptance in cell controls.

## Planning and Artificial Intelligence

Artificial intelligence (AI) is a branch of computer science studying the characteristics associated with human intelligence such as reasoning, acquiring knowledge, applying knowledge, and perceiving the environment. Path or task planning is the application of reasoning, knowledge acquisition, and perception

of the environment. Therefore, robot planning is closely related to the study of AI and certain AI techniques can be applied to robot planning and control. Some of the areas of research in AI that apply to robotic planning are problem solving, expert systems, learning, and machine vision.

The methodologies in path planning can be considered as problem solving. In assembly, when multiple components are assembled with precedence requirements, AI techniques can also be applied. Expert systems or rule-based systems solve problems in a discrete space domain based on rules derived from experts or other sources. Finally, machine vision has enjoyed a rapid increase in robotic applications. Machine vision can acquire complex environment information rapidly. Various algorithms can be used to extract useful path planning information such as locations of obstacles, end effectors, tools, etc. and can be used in real-time robot motion control. The reader is referred to Winston (1984) for more AI discussion.

## **Man-Machine Interface**

Robots can commonly be programmed or controlled through teach pendants or a computer. A teach pendant is a small key pad that allows the user to move the robot, record positions, and enter simple programs. Modern robots are also accompanied by programming and control software that runs in microcomputers or workstations. The software environment often includes an editor, menu-driven robot control, and diagnostic utilities. More intelligent robot control programming is commonly supported in this environment than is available through the teach pendant.

Control programs can also be generated off-line. In *off-line programming*, the spatial configuration of the robot and work environment is modeled in the computer. A programmer is presented with a 2D or 3D world model of the robot and its environment graphically. The programmer will specify the locations and paths in this model rather than working with a real robot. Off-line programming has the potential to improve robot productivity and simplify the procedures of creating complex robot programs.

## 14.9 Design of Robotic Systems

---

*Kok-Meng Lee*

For manufacturing in which the manufacturing facility is concerned with similar volumes of production and a wider range of parts, the assembly line/mass production method is often not cost effective. It is often desirable to group equipment units together into workcells that can, in composite, perform an entire family of related operations on the product. The work-in-progress enters the workcell, remains while several functions are performed, and then leaves the workcell.

The individual equipment units that are used in the workcell (for both processing and materials handling) can consist of combinations of manual, semiautomatic, and fully automated equipment. However, in this section, the term “workcell” refers to a grouping of the robot and its peripheral equipment to assemble any of a large variety of products with little or no human intervention, driven by electronically designed data. An assembly robot is a comparatively simple mechanism whose function is to position parts and tools in the space of its work volume accurately. It is a comparatively low-cost machine of high precision of positioning and great reliability. Its simplicity, however, excludes the possibility of human-type actions like form recognition and its prehensile tools are very far from having the number of degrees of liberty a human hand has. If we concede that an assembly robot can by no means compete with a human being in a complex task, we also have to acknowledge that an assembly robot is capable of executing monotonous tasks with consistently high precision, thereby increasing the quality of the product. It can also keep up a fast production line indefinitely. Recognizing this difference between a human and a robot is essential in the design of a robotic system.

The remainder of the section is organized as follows. A set of design considerations for designing an assembly robot workcell is first presented. Layouts for a typical robotic workcell are then discussed. Experience so far has shown that in most instances, it is a feeder that fails in the workcell, not the robot. Feeding methods must be carefully considered when designing a workcell and are discussed at the end of the section.

### Workcell Design and Layout

#### Design Considerations

Assembly systems can be broadly classified as manual, fixed, and flexible systems in relation to the complexity of the product to be assembled and to the production volume as shown in [Figure 14.9.1](#). Flexible robotic workcells are typically used for less complex products at low or medium production volume, while for increasing product complexity, the cells designed for a single-purpose task can be linked into assembly lines. Apart from product volume and complexity, the design of the robotic workcell depends on several factors: namely, number of part types, end-of-arm tooling exchange, as well as product design.

*Number of Part Types.* A typical workcell consists of a robot and its peripherals made up of part-presentation mechanisms, feeders, conveyor, and end-of-arm tooling. For a small number of part types, parts are presented to the robot by feeders or magazines. As these take up space, only a limited number of different parts can be fed to one robot. In mechanical assembly normally a maximum of five to six different parts can be presented in this way.

To extend the robot’s accessibility to a large number of parts, mechanized component feeding systems can be mounted on data-driven carousel conveyors spaced around the robot, each with a fixed dispensing point within reach of the robot gripper. The carousel can accommodate up to several hundred positions onto which magazines, tapes, or other modular dispensing systems can be attached. With multiple programmable carousels, the robot can access several thousand different parts. The application of the mechanized carousel is useful when only a few of each part type from thousands of styles may be used. Other alternatives are (1) kitting, in which all components to be assembled are kitted in a loosely

FIGURE 14.9.1 Classification of assembly systems.

palletized waffle pack, and followed by more accurate location using standard machine vision; and (2) the use of accurate totes for robot handling.

*End-of-Arm Tooling Exchange.* Many systems use different gripper exchange systems in order to cope with different parts. Tool exchanges are often considered as “nonproductive” since they do not contribute to assembly operations. The exchange is serially coupled to the assembly operations. This means that the cycle time increases due to the extra time needed for pickup and drop-off for tool changes as well as travel time between the assembly point and the end-of-arm tooling station. In order to reduce time loss due to the gripper, exchange should be minimized and/or in parallel with other activities, and the distance between pick-up point and assembly point should be very short. This problem could be avoided if a fast-revolving gripper head is used provided that space, weight, and cost of the revolving head do not pose a problem. Alternatively, the pallet carries batch-specific equipment such as grippers, fixtures, and end-of-arm tooling and can be presented to the robot on a conveyer in a similar fashion as the parts.

*Product Design.* Product design for flexible automation cells includes the following criteria: task operations based on flexible assembly cells for specific product families which must be able to assemble the variants of these product families using programming, fast changeover from one product to another within a flexible assembly cell, and reuse of standard elements for new assembly tasks

In addition to product complexity and volume, two other criteria should be considered in the construction of flexible assembly cells. First, since only a few products are generally suitable for fully automatic assembly, manual working processes are often essential with a large number of products. Flexible assembly cells must be constructed so that manual work stations can be included following ergonomic principles. Second, since the type-specific peripheral costs will increase in relation to the number of individual parts in the product to be assembled, part-specific feeders must be minimized for the economic use of flexible assembly cells.

### Workcell Layout

Workcell design and layout in a flexible automation system depend on the nature of the manufacturing processes, the product design, and the material handling system as a whole. The manufacturing systems are classified as electronic product assembly, subassembly of electrical and mechanical components, and kitting cell for large-scale manufacturing.

*Electronic Product Assembly.* Flexible workcells are commonly used for the assembly of integrated circuit boards (PCB), where a combination of interchangeable part-feeding mechanisms are used to present parts to robots. Since a majority of the processes involved are carried out in the linear, vertical plane, robots of SCARA or gantry construction are best suited for these assembly tasks. The workcell

consists of a robot and its peripherals made up of part-presentation mechanisms, feeders, conveyor, and end-of-arm tooling.

Figure 14.9.2 shows the organization of a typical workcell for assembly of a family of circuit boards (Decelle, 1988), which is a part of the in-line component insertion, inspection, and repair assembly line. Circuit boards to be assembled are secured on panels and flow through the workcell on a conveyor. Each of the circuit boards is characterized by a bar-coded serial number that permits product tracking, data collection, and testing through the assembly. Boards requiring assembly are positioned over an elevator mechanism in the workspace of the robot. The mechanism lifts the board slightly and uses the tooling holes on the panel to locate the circuit board. Two digital signals interface the conveyor to the workcell — one signals the robot that the board is ready for assembly and the other signals the conveyor to index the board to the next workcell. Components are fed to the robot by using feeders. The feeder singles out components to a walking-beam mechanism that transfers parts through lead-cutting, lead-straightening, and lead-verification operations and on to the lead-locating nest for robot pickup. The activities of the robot and its peripherals in a workcell are coordinated by a host computer. The workcell is set up and monitored through the host computer. Through the host computer, the operator provides the workcell the code to be assembled, the components in the feeders, and the configuration of the feeders.

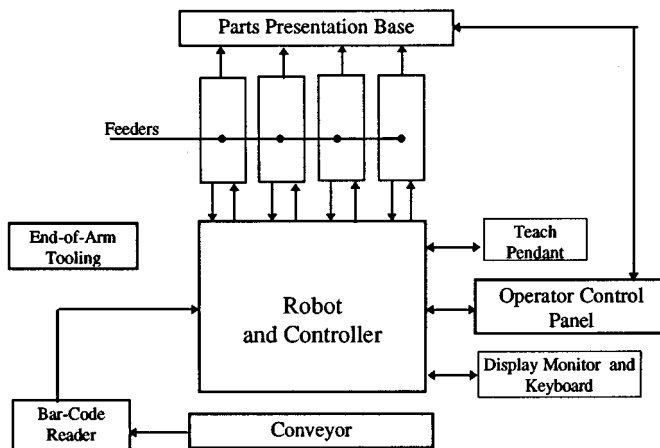

FIGURE 14.9.2 Workcell for electronic assembly.

*Subassembly of Electrical and Mechanical Components.* Unlike PCB assembly, packaging and designs of small electrical and mechanical components are generally nonstandardized. Thus, the problem of automated flexible assembly workcells lies in the presentation of parts and the degree of flexibility of assembly of small components often involves both product design and layout considerations extensively.

Figure 14.9.3 shows a self-contained flexible workcell for assembly of small mechanical parts with a circular indexing table. Modular part-feeding equipment such as vibrator feeder bowls and special-purpose trays are placed around the indexing table to feed and to orient small components to the robot. Typical mechanical operations such as riveting, screwing, welding, inserting, pressing, and so on are achieved through quick changeover end-of-arm tooling. The circular indexing table arrangement is advantageous where end-of-arm tooling changes are necessary for handling different parts. It allows changes of end-of-arm tooling to take place while other operations are continuing.

With complex products, assembly in a single flexible assembly cell is not always feasible. In this case, a flexible assembly line can be designed to link self-contained independent workcells (Figure 14.9.3) so that they can be engaged or disengaged as required to allow adaptability in connection with product model change. Alternatively, standard carriers or pallets can be used to present a large number of different part-types to a robot. Each pallet carries a large number of identical parts, unoriented but

**FIGURE 14.9.3** Typical single-purpose workcell.

with the right side up, and placed on a flat board. Standard machine vision was used to detect the orientation of the parts.

*Kitting Cell for Large-Scale Manufacturing.* In the field of large-scale manufacturing such as automobile manufacturing, engine assembly, and machining processes, where the setup time of specialized tools for each task is excessive, the work is generally distributed into several cycle zones. As an example, actual cutting time (production time) represents a value between 5 and 20% of average machine utilization time that includes nonproductive time accountable by workpiece load/unload, tool change/setting, and workpiece inspect.

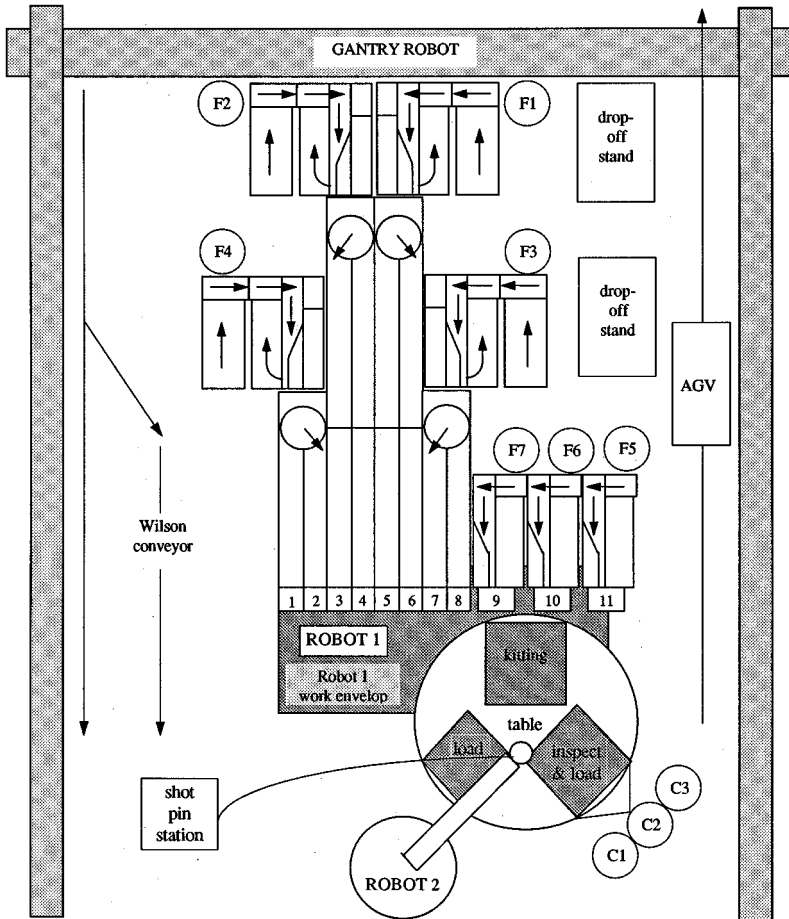

To avoid a high level of wear and tear on tools due to constant conversion, the cycle zone is commonly divided into individual operating cells which may be interconnected in series, parallel, or a combination of series and parallel. A typical workcell (Figure 14.9.3) consists of a robot, a part-feeder, an end-of-arm tooling section, and the manufacturing process. The parts are contained in a regularly spaced pallet, which are transported by means of an automated guided vehicle (AGV) or a conveyor to the loading tables and are fed to process by the robot. The most common approach in automated part presentation for machine loading is the use of specially designed pallets for each part family to maintain sufficient position accuracy for a completely preprogrammed robot picking.

In the case of assembly, purchased parts or parts to be processed are kitted onto one kit tray in a single location. Kitting is the process of taking parts from bulk and placing them on a kit tray, which is an organized group of parts. Concentrating the material delivery system and its control to one area is the main benefit of the kitting cell. In addition to efficient use of floor space by eliminating duplicate equipment at each assembly cell, the feeders and tooling are universal — the same equipment is being used all the time for all parts, thus maximizing utilization while minimizing capital expense. The material delivery equipment is eliminated at the assembly cycle times. Also, having all the parts for an assembly on a carrier permits changes in the process route during machine downtime or blockages.

Figure 14.9.4 shows a layout of the kitting cell. An overhead gantry takes bins of parts and dumps them in the appropriate feeders (indicated in Figure 14.9.4 as F1, ... F7). The feeders fill the lanes with an initial quantity and replenish them as parts are kitted. The parts come to rest in nests at the end of the feeder lanes. Here the vision system verifies the correct part family, performs some quality checks, and determines the position and orientation for the robot to pick the parts. Should the vision reject the part, the nest will dump the part and a new part will be fed in for an inspection. Using a quick changeover gripper, multiple parts are kitted onto a tray. Once all the parts are on the kit tray, the tray is indexed to the inspection station for verification that all parts are placed. The robot takes the completed kit tray and places it on the assembly conveyor to an idle station, ready to be picked up by an AGV.

## Part-Feeding and Transfers

The term “part-feeding” refers here to feeding workpieces from pallets using a preprogrammed robot for subsequent processes such as machining or assembly. The cost to feed parts to a robot for either

**FIGURE 14.9.4** Schematics of the kitting cell.

machine loading or assembly in a flexible manufacturing system (FMS) has often been underestimated, which may comprise as high as two thirds of the overall investment and is usually the source of a large percentage of work stoppages and defects. A general review of existing *mechanical part feeders* can be found in Lee (1991).

The basic kinds of part-feeding may be classified as follows: (1) mechanical feeders which are designed to feed and to orient the parts-dedicated part-feeding apparatus, (2) dimensionally dedicated pallets which are specially designed for each part family to maintain the position/orientation, and (3) machine vision.

**Mechanical Feeders**

The commonly used mechanical feeders for robotic assembly are bowl feeders, vibratory feeders, and programmable belt feeders. For large volume manufacturing, the employment of the dedicated mechanical part-feeding apparatus may be justified. However, mechanical feeders consume a lot of room around the workcell, often fail due to jamming, and, most significantly, generally require retooling when a component is changed or tool wear is caused by jamming.

*Vibratory Bowl Feeders.* Vibratory bowl feeders (Boothroyd and Dewhurst, 1985) are most commonly used as mechanical feeders for robotic assembly. The basic component of a bowl feeder consists of a

vibratory bowl, a rotating disk, and an orienting track. Parts to be fed to the robot are separated into a single line and oriented to move to feeding end. These feeders, in general, are not designed to be easily converted to feed new part types. The cost of the bowl feeders can be broadly divided into two parts: special purpose equipment cost and general purpose equipment cost. Typically, changeover would involve replacing the bowl, orientation track, feed track, and escapement, which contribute to special-purpose equipment cost. Only the vibratory drive unit could be reused. This general-purpose portion of the feeder is approximately 30% of the feeder cost.

One way to lower the cost of the bowl feeder per part is to deliver different parts to a robot assembly station using multiple layer vibratory bowl feeders. A multilayer bowl feeder has several bowls mounted in stacked fashion, and in each bowl a different kind of part is stored. The design of multipart vibratory feeders aims at reducing the cost of the vibratory feeders by sharing the general-purpose hardware cost over several parts and by reducing the special-purpose tooling cost. Two basic forms are available: bowl type and in-line type.

To change over this multipart vibratory feeder to other part types, the orienting tracks must be replaced. An effective way to reduce wear is to separate the function of orienting from feeding. The function of the multilayer vibratory feeders is to restrict feeding parts to a separation unit. Parts of several different types are fed but not oriented from a vibratory feeder. In most cases, the workpieces must be held by a mechanical pusher against a pair of orthogonal datum planes on a relatively flat surface with the “right side up.” A machine vision system is then used to locate and/or to sort the orientation of the parts using two-dimensional binary images, which is a great deal easier to store and to process.

*Vibratory Belt Feeders.* In vibratory belt feeders, parts are fed by a vibratory conveyer belt (Boothroyd and Dewhurst, 1985). The principle of the vibratory belt feeder is to produce a vibratory motion on the surface of the brushplate. The motion is obtained by pulling the brushplate sharply down and back and then allowing it to spring up and forward. This action, repeated at high speeds (approximately 3600 times per minute at 60 Hz power supply), produces a definite vibrating movement on the brushplate surface, permitting parts to be conveyed in a smooth and easily controlled manner.

The orienting systems used on these belt feeders may be a mechanical device, an optical sensor, or a vision system. A machine vision system is often used to locate and/or to sort the orientation of the parts using two-dimensional binary images. A line-scan camera is commonly used to create the silhouettes of the workpieces, and in some cases the product designs can be reviewed to simplify the vision algorithm and to reduce the system cost. Since a robot gripper can grasp parts from a queue on the feeder itself, belt feeders do not require any special-purpose tooling for feed track or escapement and thus offer several advantages over the vibratory bowl feeder for robotic assembly

### **Dimensionally Specific Pallets**

One of the most common approaches is the use of specially designed trays or totes for each part family to maintain sufficient accuracy for a completely preprogrammed robot picking. A particular form of these dimensionally precise feeders is known as tape-and-reel for feeding parts of relatively small sizes, which can be placed on tapes of standard width. For some devices that are large, heavy, ceramic, or have fragile leads, tapes are very expensive and impractical.

In general, the dimensionally specific pallets are well suited for large volume production where changes of part types are not frequent. The operational cost of the design-specific pallets includes packaging costs for transport, construction cost for pallet alignment, and engineering cost for new pallet designs.

### **Vision-Based Flexible Part-Feeding**

For flexible manufacturing, where a large variety of product sizes and component types are encountered, the part-feeding system must have the ability to adapt to a changing product design without costly hardware redesign or time-consuming software reengineering. This need has been addressed as a general industrial vision-based bin-picking problem by several authors.

In manufacturing automation applications, the processing speed of acquiring and analyzing an image must be comparable to the speed of execution of the specific task. The attempt to duplicate human

perception by obtaining a three-dimensional detailed image of the part often calls for time-consuming computation and does not necessarily determine the location and orientation of a given part with the accuracy required for successful part acquisition by the robot. Moderate location inaccuracies pose no difficulty for human operators since they use vision, hand-eye coordination, and sense of touch to locate and correctly load the part.

However, if the orientation of the parts can be characterized by the two-dimensional object silhouette, retroreflective materials can be used as a background in generic part presentation (Lee and Li, 1991). Most surfaces on objects exhibit a combination of diffuse and specular reflection. A point on an ideal diffuse-reflecting surface appears equally bright from all viewing directions. Surfaces covered with papers and matte paints may be considered as reasonable approximations. An ideal specular reflector is one that reflects any incident light ray as a single ray in the same plane as the incident ray and the surface normal. The basic principle of the retroreflective vision sensing is to structure the surface reflectance of the pallet or the landmarks so that it is much brighter than objects generally characterized by diffuse or specular surfaces. In practice, a number of unpredictable factors such as measurement noise, the uniformity of the surface reflectivity, and the uniformity of illumination, which occur on both the object and the background, can be eliminated by a relatively simple technique. If part design can be modified, brightly illuminated retroreflective landmarks can be intentionally created on objects for location tracking. Low cost landmarks could be incorporated in design by using retroreflective liquid paints on existing features. Alternatively, generic landmarks can be constructed by applying solid glass beads on the reflected surface of standard fastening devices such as screw heads.

## 14.10 Robot Manufacturing Applications

*John W. Priest and G. T. Stevens, Jr.*

### Product Design for Robot Automation

Identifying automation opportunities early in product design is important because product design requirements to facilitate robotic manufacturing are often unique and must be integrated early in the product design process. Some overall manufacturing problems for using robots and some design solutions to resolve these problems are listed in [Table 14.10.1](#).

**TABLE 14.10.1 Design Solutions for Robots**

Problems in Utilizing Robotics	Design Solutions to Assist Production
Location accuracy and repeatability	Design for vertical assembly; use chamfered edges for mating surfaces; tolerance leeway for mating parts
Part feeding and orientation	Design parts which can be easily fed, provide notches, guide pins, or slots for part orientation; select parts from vendors that will deliver in easy-to-feed packaging
Programming robot and associated equipment	Design simplification; use common parts for different products, part reductions; part families
Application problems with fasteners (screws, washers, and nuts)	Minimize the use of all fasteners; utilize snap fits where possible
Downtime caused by jams and misfeeds due to poor part quality	Select vendors that produce high-quality parts

Rossi highlighted the product designer's role in robotics stating this problem (Rossi, 1985):

Often designs are made in such a fashion that one cannot access a certain area with a robot. Humans can get around obstacles and operate within those designs easily, but robots cannot because they are not quite as flexible as human beings. I think that this is the single most important item that has kept us from being further along than we are. What happens is that users try to apply a robot to something that's been designed without robotic assembly in mind. They usually run into a problem. Either the robot cannot handle it at all or the users find that they have got to put a lot of additional engineering design into a particular workcell, or perhaps into an end effector, in order to get around the problem. All this does is add to the price tag, and cost is very much in consideration when one is trying to sell these systems. A situation arises where robots are no longer attractive because of all the additional things that need to be done.

In summary, the product must be designed for the manufacturing process and the robot. For more information, the reader should review Boothroyd (1994), Bralla (1986), Priest (1988), and Tanner (1994). [Table 14.10.2](#) shows some design rules for robotic assembly.

**TABLE 14.10.2 Design Rules for Robotic Assembly**

Product should have a base part on which to build assemblies in a top-down, straight-line motion direction
Base should be stable and facilitate orientation
Parts should be able to be added in layers
Use guide pins, chamfers, and tapers to simplify and self-align the layering of parts
All parts should accommodate handling by a single gripper and be comparable with popular feeding methods
Sufficient access is available for the gripper
Avoid the use of bolt-and-nut assembly
Parts should be able to be pushed or snapped together; when screws are necessary for repair, they should all be the same size
High quality parts are used
Vendors deliver parts that are compatible with the selected part feeder mechanism

## Economic Analysis

Economic analyses for robotic applications are similar to those for any manufacturing equipment purchase and usually use minimum annual revenue requirements, present value methods, or break-even analyses. Since robots are a flexible method of automation, a unique aspect of robotics is manufacturing's ability to reuse the robot after its initial production run for other applications in later years. For many companies, this subsequent use of the robot can be shown in the economic evaluation. Some other unique benefits in robotic economic analysis that may be included are improved quality, higher precision, ability to run longer shifts, and reduced floor space. Unfortunately, some unique disadvantages of robot analysis are software integration complexity, inability to respond quickly to product design changes, and process reliability.

In general, there are several situations where robots are more likely to make economic sense. These are

- A. Sufficient volume to spread investment costs over many units
  - 1. High volume
  - 2. Stable product design
  - 3. Multishift operations
- B. Robot is used on more than one product
  - 1. Limited number of different products on same production line
- C. Part handling problems occur when performed manually
  - 1. Parts that are very large, heavy, or bulky
  - 2. Parts that are very fragile or easily damaged
  - 3. Parts that are extremely small
- D. Extremely difficult manufacturing process without using robot or automation
  - 1. Many processes, especially in electronics, cannot be performed without robots or some type of automation
- E. Safety and health concerns of process
  - 1. Safety and health costs can be significant

The type of data concerning the robot system that is required for an economic analysis is shown in [Table 14.10.3](#).

**TABLE 14.10.3 Economic Cost and Savings for Robot Applications**

---

### Investment costs

- Robot purchase price — for many applications this is a much smaller part of the costs than expected (25 to 45%)
- Other equipment (part feeders, conveyors) — this includes the cost of hardware interfaces
- Design of end effector, special fixtures, and other equipment — most applications require the design of a unique end effector and special fixtures
- Software design and integration — can be a much higher cost than expected due to the complexity of interfacing different equipment controllers
- Installation including facility modifications — usually a small cost for robot system
- Technical risk — this is the risk of whether the system will perform up to the specifications in areas such as performance, quality, precision, etc.

### Operating costs

- Training — costs of training operators, engineering and maintenance personnel
- Product design changes — cost required to modify the robotic software and hardware when design changes or modifications are made to the product
- Operating, utilities, and maintenance — typical costs found for most manufacturing equipment

### Savings

- Direct labor — labor savings caused by the robotic system
  - Ergonomic and health — benefits of lower number of job injuries, workers compensation costs, and compliance with OSHA regulations
  - Quality — improved quality may result due to lower scrap and waste
  - Precision — robots can often perform tasks at a much higher precision (i.e., lower variability) than manual operations resulting in fewer defects and better product performance
-

### Cost Justification for Robots

In this section an example of a robot justification study is presented. This example uses the discounted cash flow method resulting in the calculation of a rate of return (often referred to as the internal rate of return).

The rate of return,  $R$ , is defined by Equation (14.10.1) as

$$0 = \sum_{j=0}^n \frac{X_j}{(1+R)^j} = \sum_{j=0}^n X_j (P/FR, j) \quad (14.10.1)$$

where

$X_j$  = the net total cash flow for year  $j$   
 $n$  = number of years of cash flow

Basically, the rate of return,  $R$ , is the interest rate that makes the sum of the discounted cash flows equal zero.

The net cash flows,  $X_j$ , in Equation (14.10.1) can be defined by Equation (14.10.2):

$$X_j = (G - C)_j - (G - C - D)_j(T) - K + L_j \quad (14.10.2)$$

where

$G_j$  = gross income (savings, revenues) for year  $j$   
 $C_j$  = the total costs for year  $j$  exclusive of book (company depreciation and debt interest)  
 $D_j$  = tax depreciation for year  $j$   
 $T$  = tax rate (assumed constant)  
 $K$  = total installed cost of the project (capital expenditure)  
 $L$  = salvage value in year  $j$

A numerical example is now presented using the data given in [Table 14.10.4](#). The values in [Table 14.10.4](#) should not be considered representative. They are used only for example purposes.

**TABLE 14.10.4 Data for Numerical Example**

Project costs	
Purchase price of robot	= \$40,000
Cost of end effector	= \$10,000
Software integration	= \$20,000
Cost of part feeders	= \$10,000
Installation cost	= \$ 4,000
	\$84,000
Yearly operating costs	= \$10,000
Yearly savings	
Labor	= \$60,000
Quality	= \$10,000
Tax rate	= 40%

The first question that must be answered is, what is the capital recovery period (life of the economic study)? In this example 3 years is used. The next question is, what is the yearly tax depreciation? This example uses MACRS (3 years). Therefore, the percentages used to determine the yearly tax depreciation amounts are those given in [Table 14.10.5](#). It should be noted that [Table 14.10.5](#) implies there are 4 years of tax depreciation. This is because the MACRS system uses a half-year depreciation convention. In this example, it is assumed there is sufficient taxable income from other operations that allow the use of the depreciation amount in year 4. In this example, the salvage value is assumed to be zero.

**TABLE 14.10.5 MACRS Percentages**

Year	Percentage
1	33.33
2	44.45
3	14.81
4	7.42

Using Equation (14.10.2), it is now possible to generate the cash flows shown in Table 14.10.6.

**TABLE 14.10.6 Net Cash Flows**

EOY	K&L	G	C	D	X
0	\$84,000	—	—	—	84,000
1		\$70,000	\$10,000	\$27,997	47,199
2		70,000	10,000	37,338	50,976
3		70,000	10,000	12,440	40,976
4	L = 0	—	—	6,224	2,490

Some sample calculations follow:

$$\begin{aligned}
 x_0 &= -\$84,000 \\
 x_1 &= (70,000 - 10,000) - (70,000 - 10,000 - 27,997)(.40) \\
 &= \$47,199 \\
 x_4 &= -(-6224)(.40) \\
 &= \$2,490
 \end{aligned}$$

With the cash flows in Table 14.10.6 the rate of return can be determined using Equation (14.10.1):

$$0 = -84,000 + 47,199(P/FR,1) + 50,935(P/FR,2) + 40,976(P/FR,3) + 2,490(P/FR,4) \quad (14.10.3)$$

To determine R in Equation (14.10.3), a trial-and-error solution is required. Assuming 20%, the right-hand side of Equation (14.10.3) gives \$15,619 and with 25%, it is \$-17,262. Therefore, the rate of return, using linear interpolation, is

20%	\$15,619
<i>R</i>	0
25%	-17,262

$$\begin{aligned}
 R &= 20 + \frac{15,619}{32,881}(5) \\
 &= 22.38\%
 \end{aligned}$$

This rate of return (22.38%) is now compared to a minimum acceptable (attractive) rate of return (MARR). If  $R \geq \text{MARR}$ , the project is acceptable. Otherwise, it is unacceptable. It is pointed out that the definitions of cash flow and MARR are not independent. Also, the omission of debt interest in Equation (14.10.2) does not, necessarily, imply that the initial project cost (capital expenditure) is not

being financed by some combination of debt and equity capital. When total cash flows are used, the debt interest is included in the definition of MARR as shown in Equation (14.10.4).

$$\text{MARR} = k_e(1 - c) + k_d(1 - T)c \quad (14.10.4)$$

where

$k_e$  = required return for equity capital

$k_d$  = required return for debt capital

T = tax rate

$c$  = debt ratio of “pool of capital” used for current capital expenditures

In practice, it is not uncommon to adjust (increase)  $k_e$  and  $k_d$  for project risk and uncertainties in the economic climate. There are other definitions of cash flow definitions (equity and operating) with corresponding MARR definitions. A complete discussion of the relationship between cash flow and MARR definitions is given in Stevens (1994).

## Assembly

Assembly is projected to be the largest area of growth for robots. Key design goals for robotic assembly are to ensure high-quality parts, minimize the use of fasteners and cables, and provide accessibility so that parts can be easily fed and oriented by automated equipment. Designing to facilitate the use of robotics requires a review of their capabilities. Although assembly robots are often shown as stand-alone equipment, they require considerable amounts of support tooling and auxiliary equipment. These include part feeders, end effectors, special fixturing, and a material handling system. Except in the case of robots with vision or special sensors, parts with which the robot will interact must be precisely located and oriented. This may require additional tooling or special vendor packaging.

Assembly is defined as the combining of two parts into one entity. This combining process may include (1) the use of mechanical fasteners (i.e., screws, snap fits, rivets, etc.); (2) joining processes such as welding, brazing, soldering, etc.; (3) application of adhesives; (4) the simple process of placing two parts together to be joined together later.

Robotic assembly is the use of robots to perform one of these assembly processes. A typical set of tasks for robotic assembly using mechanical fasteners might be

1. Go to location  $(x_1, y_1, z_1)$  and grasp part A (assumed to be properly positioned and oriented).
2. Place part A in a fixtured assembly position  $(x_2, y_2, z_2)$ , including proper orientation).
3. Go to location  $(x_3, y_3, z_3)$  and grasp part B (assumed to be properly positioned and oriented).
4. Place part B on part A  $(x_4, y_4, z_4)$  including proper orientation.
5. When an additional process is needed, fasten or join part A to part B using process tooling.

As can be seen in this simple list of tasks, developing robotic assembly system focuses on getting the parts to be assembled in the proper position and orientation and the combining process itself. Because of this, the rest of this section will describe the parameters of these two aspects: part feeding and presentation and the combining process.

### Part Feeding and Presentation

Robot assembly requires the robot to go to a predefined location and grasp a part. The part may be positioned and oriented or it may not. Since a positioned and oriented part is preferred, part-feeding methods that can perform this task are desired. The most popular types are

1. Vibratory bowl feeders
2. Pallets and trays
3. Specialized feeders
4. Special vendor packages

## 5. Conveyors

Vibrating bowl feeders are one of the most popular methods due to the large number of parts that it can feed and its cost effectiveness. Pallets, in turn, are popular for many electronic parts and fragile parts where the part cannot withstand the forces found in a vibrating bowl feeder. Specialized feeders are those feeders that are usually designed for a particular type of part. These can include tube feeders, magazine feeders, and slides. Vendors can often provide parts in specialized shipping packages which keep the parts in the proper position and orientation. Finally, when the parts are delivered by conveyor, special fixturing and stops can often be placed on the conveyors to position/orient the part.

When the part is not positioned or oriented, additional sensors must be added to the system. Commonly used sensors are

- Machine/robotic vision
- Simple sensors such as photodiodes
- Tactile/touch sensors

Robotic vision is becoming more popular in assembly as their purchase, software integration, and installation costs continue to decrease. Although most robot manufacturers offer vision systems as an option, they are still an expensive addition to the system. Simple on/off sensors can be used in certain cases when only limited data are required. Tactile sensors can sometimes be used to touch/feel the part to identify specific features of the part or to recognize its location.

### **Combining Process**

After the parts are placed together, the combining process will often require the robot to perform some process operation. This can include an additional equipment such as a fastening gun for a screw, adhesive applicator and pump for a bonding operation, or a solder gun for soldering. Most robot manufacturers can offer equipment for the various types of assembly processes.

For more information on robotic assembly, the reader should review Asfahl (1992), Groover (1986), Klafter et al. (1989), and Sandler (1991).

## 14.11 Industrial Material Handling and Process Applications of Robots

---

*John M. Fitzgerald*

Replacing humans with robots to perform processes has often led to failure. The reason is that the robots are often mechanically capable of the manipulation while being incapable of process planning and control. Thousands of robot installations have failed because replacing the manual method with the automatic method lacked adaptability to process related variation. The human operators had been using their cognitive abilities to do the job. A vast majority of successful robot implementations past and present have a very important common aspect: repeated execution of fixed programs with little or no on-line modification of path or position.

Process robot planning and programming still usually require the efforts of highly skilled technicians. Often, complex programs cost too much and take too long. Continuously controlling and varying path manipulation parameters for real-time process control is difficult. Many processes are not known well enough to describe their control algorithmically. In a few applications sensors are becoming more common for adapting robot plans to changes in the environment. Setup, seam tracking, positioning, conveyor tracking, and now automatic programming for painting and finishing are becoming practical as sensor costs and computation costs continue to decline.

In this section robotic material handling and process applications are presented from an automation system perspective focusing on the robot's manipulation functions. Manipulation is considered a manufacturing material transformation and a transportation process factor. Programming and control are viewed as the means of integrating robot manipulation as part of the manufacturing process. The reader who is interested in a specific application is encouraged to first review the relevant process technology sections of this book.

### Implementation of Manufacturing Process Robots

#### Manipulation as a Process Requirement

The starting point of automation system design is a thorough understanding of the process to be automated. Implementation of a process robot requires a focus on manipulation as a process factor. The pose and path requirements of the process are independent of the manipulator used.

It is useful to conduct a static spatial analysis of manipulation requirements and then examine the mechanical and dynamic requirements when designing or selecting a process robot manipulator.

A spatial description of the relative positions and orientations of the workpiece and tool during processing provides the basis for describing the required manipulation. *Tool poses* are graphed in an appropriate reference frame, usually the frame of the workpiece, or in the case of machine loading, the work holding fixture may be used. Path requirements are secondary for these applications. The path taken does not affect the process. For *continuous path processes* entire paths must be graphed or mapped. If continuous analytical descriptions of the path are not available, a sampling of discrete points along the required path can be used to represent the space occupied by the path. The result in both cases is a Cartesian mapping of spatial requirements of pose and path. A description of the pose and path precision requirements should be included. Next the mechanical and dynamic requirements are defined. Payload and force reactions at each position and along the path must be understood. Other important dynamic requirements such as acceleration and power should be quantified. The manipulation requirements are the basis for design and selection of both the robot arm and the controller.

#### Manipulation Capability of Process Robots

The basic mechanical capability of the robot mechanism to perform the manipulation work is determined by its mechanical structure, kinematic configuration, and drive mechanism. There are several applications including painting, palletizing, spot welding, and arc welding for which specific types of robot arm

designs have evolved driven by process needs. Although predisposed by design to perform a particular process, these robots have no innate process capability and are not guaranteed to perform in a specific application. Specifications of gross robot performance characteristics such as reach, *repeatability*, accuracy, and payload are usually readily available from their manufacturers. A well-defined set of process manipulation requirements when compared with published robot specifications usually isolates the field of mechanically qualified candidates. It is more difficult to characterize and evaluate a robot's capability for complex motion. The exact working of the robot's trajectory generation software is usually not known by end users and can only be evaluated by indirect testing. Acceleration and load capacity are usually specified, and there are some standard methods for specifying path performance, but the robot's dynamic behavior and performance are difficult to measure. Specific performance testing is usually required to prove manipulability for process robot applications.

### **Integration of Manipulation Control and Process Control**

Achieving manipulator and process control integration depends upon robot programming and external data access. For any given application the required motion execution may be possible, but programming may be too difficult to be practical. Establishing that the robot is capable of coordinated motion can be done by reviewing the specifications or by conducting motion tests. As an illustration of the importance of programmability consider, for example, a situation in which a complex series of twisted curves define a robot tool path. If two robots with identical kinematic structure and joint trajectory generation capability differ in their programming in that one is capable of executing paths following user-defined mathematical functions and the other is only capable of executing paths defined by closely spaced taught poses, the difference in programming effort could easily amount to hundreds of hours. For each application encountered the programming methods must be assessed to determine if the required motion is programmable in a practical sense.

Access by process robot programs to external data is becoming more important. Although most process robots now work without any external process feedback, this is beginning to change rapidly with the development of improved low cost sensor systems and methods. Virtually all robots are capable of discrete digital and analog signal input and output. Most may also be equipped with standard serial and parallel communication capacity. If sensor information is to be used for set-up positioning or real-time path adjustment, the robot controller must have the communication and control to convert data into information that can be used to modify path and position commands. In cases of extreme path complexity, path planning systems external to the robot controller may be needed to create the paths. Testing will verify the ability of the robot controller to accept and execute externally generated motion sequence data.

## **Industrial Applications of Process Robots**

### **Palletizing and Depalletizing**

Many products are packaged in boxes of regular shape and stacked on standard pallets for shipping. Robots are commonly used to palletize and depalletize boxes because they can be programmed to move through the array of box positions layer after layer. Although palletizing is more common than depalletizing, there is no major functional difference in the manipulation requirements. Transport distances of several feet are common. Stack heights usually do not exceed 5 ft. Payload weight can be in excess of 100 lb. When standard servo-driven joint actuators are used accuracy and repeatability will usually be far better than the required box positioning precision.

Palletizing typically requires four axes of controlled motion — three for translation and a fourth for yaw to orient the box. Cylindrical coordinate robots are favored in palletizing because they have large vertical lift and a compact footprint allowing more of the floor area in the workspace for conveyors and pallets. When larger workspace is needed gantry robots must be used. Continuous duty cycles are not uncommon and robot power is important for maximizing throughput. The most technically demanding aspect of system design is the gripper. Vacuum grippers are popular for lifting boxes by their tops, but other more complex gripping methods are sometimes needed. Payloads must be carefully positioned

with respect to the robot's wrist and other links to balance gravitational and dynamic loading. Load shifting during high acceleration moves can result in dropping or mislocating the box.

Palletizing position arrays are usually taught or programmed relative to a corner or keystone box position as a reference so that the entire array can be shifted by redefining that one position. Programs are simple and easily modified to adapt to changes in box dimensions. Monitoring is done by checking the state of discrete proximity and vacuum sensors. A proximity sensor mounted on a gripper will indicate if an object is at an expected location; or the same simple proximity sensor may be used to stop the robot in the correct location to pick up a box from a stack of unknown height when the top of the box is encountered. Vacuum pressure switches are often used to verify acquisition by suction cup. A simple proximity switch can be used to signal the presence of an expected package at the pick-up point. With careful timing and additional sensor inputs, items can be transported to and from moving conveyors.

### **Packaging**

Packaging is often a combination of palletizing and assembly-type actions. A collection of objects which may not be identical are inserted into a box or other container. The robot may also be required to assemble, place dunnage, seal, or mark the package. Insertion may simply require positioning the pack item over the opening of the package and dropping it. Boxes most often are supplied partially assembled, printed, and folded flat. Usually human operators or a special machine will open and prepare the box for packing; rarely will the robot be used for this purpose. Often the robot can be used to place cardboard layer separators, foam, or cardboard holding forms and other protective dunnage in the box. Finally, sealing and marking operations may be performed by the robot. Pack items may require complicated assembly-type motions such as rotations and curved moves to clear other packed items.

Three to six axes of motion may be needed. Packing items with a variety of sizes, shapes, and other varying physical properties into one package have the potential to complicate motion and tooling requirements. Grippers can be designed with multiple functions or they can be designed to be exchanged by the robot at tool storage racks. When material throughput is high, a single robot may be dedicated to each pack item. Simple programming methods are employed such as teach programming. Discrete sensors are useful for monitoring grip status of pack items.

### **Machine Tending: Loading and Unloading**

Forges, stamping process, some machine tools, and molding machines are now commonly tended by robots. Historically these types of machines have been loaded by human operators. Now these jobs are considered to be too arduous and hazardous. An important benefit of robotic machine loading is improved product quality resulting from consistent machine cycles. Robots eliminate the inconsistencies of human-paced loading and as a result the cycle can be precisely repeated. For heated molding, stamping, and forging processes, part formation and release are sensitive to the thermal state of the machine. If a machine is left open for loading for differing amounts of time each cycle, significant cooling variations result in potential sticking and geometric flaws. When robots are used, the process can be tuned to the consistent robot loading cycle.

Machine loading is usually more demanding than other material handling applications because part orientation and placement are critical and may require locating mechanisms such as tooling pins and pads and/or sensor logic to guarantee interface between the robot and the serviced machine. Accuracy is usually not an important factor because the loading stations are permanently located in the robot workspace, but repeatability requirements may be as small as several thousandths of an inch. Payloads can range from a few ounces to several hundred pounds. Grippers for machine loading may also require tooling pins and pads to locate and orient parts and to mate precisely with the machine's part holding fixture. The gripper may dock with the holding fixture and then transfer the part when loading clearances are very tight.

The entire range of robot types, sizes, and configurations is used for machine tending. Articulated arm robots are needed when dexterous manipulation is required to transport parts through the maze of clamps and spindles and other protrusions and obstacles found on some machines or when part orientation

must change for loading. Applications where the robot is dedicated to loading a single part into a single machine in high volume production are not uncommon. Position programming is usually done by teaching. It is common to monitor discrete sensors in the gripper and the loaded machine to insure proper loading before cycling the process machine.

### Sorting

Discrete parts are often sorted during production, usually as a condition of transfer to the next production station. The sort characteristics are usually distributed in some unpredictable manner so that individual inspection and handling are required. The difference between sorting and other transfer or loading robot applications is that the disposition of the part is based on information gained during the sort. The robot must have the programming functions to support multiple preprogrammed path execution triggered by the logical sort outcome conditions.

### Part Dipping

Many processes require controlled manipulation of parts temporarily submerged in some working fluid or coating material. Some common part dipping processes are the following.

*Investment Casting.* Intricately shaped and often delicate wax forms are coated with a slurry of stucco material which cures to form a mold. Later the wax is melted and drained from mold which can then be filled with molten metal. The dipping motion must be carefully controlled to prevent trapping bubbles and distorting the wax shape.

*Solder Pretinning.* Electrical contact pads and component leads are coated by dipping in molten solder as a preliminary step to assembly and soldering of the connections. A temperature-dependent flux reaction is required to achieve wetting by the solder so the robot must hold the component submerged in molten solder for a precise delay period. Speed of withdrawal is a major process variable for controlling the coating thickness of solder.

*Conformal Protective Coating.* Some electrical and mechanical components are dipped in liquid polymers to seal out moisture, air, and contamination. The viscosity of the polymer and the speed of insertion into the fluid must be controlled so that flow into small features occurs without trapping bubbles of air. Once submerged the component may be reoriented to several poses and to allow air bubbles to escape.

*Quenching.* Heat treating is a commonly used method of improving alloy properties. Various fluids are used as cooling baths. Controlling insertion and manipulation is important for control of cooling rate.

Dipping processes require precision of part insertion and withdrawal so velocity and acceleration must be programmable and repeatable. The stirring requirements may require the use of a two- or three-axis wrist in addition to the translation motion axes. Grippers may require special cleaning or cooling capability either on board or at service stations located conveniently in the robot's reach.

### Resistance Spot Welding

Robotic spot welding (see [Figures 14.11.1](#) and [14.11.2](#)) is the most pervasive robot application in the automotive industry. Resistance spot welds are formed by tightly clamping steel pieces together with opposing contact electrodes and then passing a large amount of current through the joint, welding the metal while producing a spray of molten sparks along with loud noise. Then the joint is held momentarily until the weld solidifies. Welds are made at discrete positions by moving the robot-mounted gun to pretaught poses. The spot welding process parameters, pressure and temperature, are controlled with the separate gun controller. Weld location and therefore positioning of the gun are critical.

Dexterity, payload, and quickness are critical operational requirements for spot welding robots. Gun pose repeatability is critical for consistently locating weld joints. Access to joint locations is limited because both electrodes must reach the weld site while maintaining clearance between gun frame and workpiece edges. Large articulated arm robots are typically used for most spot welding applications because of the dexterity needed and because the weight of the welding gun and associated robot-mounted

**FIGURE 14.11.1** Six-axis articulated arm robots spot weld automobile bodies on a transfer line. (Courtesy of Nachi Robotics, Ltd.)

**FIGURE 14.11.2** Spot welding operation simulated in off-line programming environment. (Courtesy of Deneb Robotics, Inc.)

apparatus often exceeds 200 lb. Fixed cycle programs are typical which may require several man-months to develop and less than a minute to execute. The robot spot welding path position names, path order, and control logic can be developed off-line, but lack of robot positioning accuracy characteristic of large articulated robots requires the weld positions for each individual robot to be taught by posing and recording them manually. This takes advantage of the robot's repeatability which is often orders of magnitude better than its accuracy. Unfortunately, when a robot that has been teach programmed is replaced by another robot, even an identical model, hours or days of teaching will be required to bring the replacement robot on line. Practical new PC-based calibration methods which eliminate this problem by effectively improving accuracy are now becoming commercially available.

### **Drilling**

Hole drilling is a precision machining process. Most robots cannot hold a drill spindle rigidly enough to overcome the drilling reactions and most robots cannot generally move in a precise enough straight line to feed the drill. Drilling robots use special drilling end effectors which locate and dock onto the work piece or a fixture. The robot wrist and arm must be compliant and forceful enough to hold the drilling end effector firmly into location against the fixture or workpiece. Drilling end effectors have a spindle motor and a feed mechanism which execute a separately controlled drilling cycle while the robot holds the end effector in position.

The robot's only contribution to the process is to move the drilling end effector into its docking or holding place. Drilling robots have been used most successfully in the aerospace industry because airframe structures require thousands of holes to be placed precisely and in complex orientations. Manipulability requirements for drilling are similar to those for spot welding. The drilling end effector weight will tend to be less than a welding gun but tool holding force and reach usually impose the requirement for large robots.

### **Fastening**

Robots are commonly used for applying threaded fasteners in the automobile industry for fastening wheels, and in the electronics industry for screwing components to circuit boards and circuit boards into chassis. Robots are also used for riveting in airframe fabrication.

Fastening is an end effector position-and-hold application. The robot does not follow the threaded fastener as it turns and travels into place; the end effector uses a slide or cylinder for that purpose. Automatic nut runners and screwdrivers and the associated hardware feeding apparatus are broadly available. Since a human is no longer operating the fastening tool other means of process control are needed. Usually fastener angular displacement, longitudinal displacement, and torque can be monitored and correlated with signatures or patterns characterized for specific fastener joints. Manipulator arm and control system requirements are similar to other position-and-hold applications. Very large torque may be encountered. Torsion bars or other static mechanisms are often needed to prevent the arm from being torque loaded.

### **Inspection**

Robot inspection involves relative part/sensor manipulation to compare, measure, or detect a physical characteristic of the objective workpiece. Sensors used in robotic inspection include chemical detectors, computer vision systems, infrared detectors, sonar, laser radar, radiation detectors, capacitive proximity sensors, touch probes, X-ray cameras, particle/photon detectors, thread probes, and go-no go gauges. Robot inspection applications cover the range of manipulation from end effector position-and-hold to continues in-contact path motion. In some cases the kinematic structure of the robot is used as a spatial measuring device by incorporating surface sensors or probes in the last link as robot end effectors ([Figure 14.11.3](#)). The forward kinematic solution of the joint angle measurements sampled at a contact pose give the position in Cartesian space of the contact point. If the manipulator is stationary during the measurement then the robot's Cartesian positioning error must be added. If the robot is calibrated the error may be almost as small as the repeatability (0.001 to 0.020 in. for most industrial servo-driven

arms). If the arm is moving while measurements are made significant error may be added because of delay in sampling the manipulator joint positions.

**FIGURE 14.11.3** Robots inspect pick-up truck body prior to final assembly. (Courtesy of Fanuc Robotics, N.A.)

Programming considerations are critical because robot inspection often requires data collection at a huge number of discrete positions. When CAD data are available, off-line programming of inspection may be possible, particularly for position and sense-type inspections. Sensor tool pose requirements can be quickly and accurately defined in the CAD environment and the pose data transformed into robot workspace coordinates. When hundreds or thousands of inspection poses are required manual teach programming may be too time consuming and cost prohibitive, especially when a mix of different parts must be inspected.

### **Paint and Compound Spraying**

Paint spraying is a major application in the automotive industry. Painting booths are hazardous because the paint material is often toxic, carcinogenic, and flammable. Human painters often wear required protective clothing and breathing equipment. The paint fan projecting from the arm-mounted spray gun must be manipulated smoothly along paths that are often curved and complex.

Most robots used for painting are especially designed for that purpose. They usually have large reach, small payloads, and repeatability is usually larger than that of other types of robots and may exceed  $\pm 0.010$  in. Painting robots are typically six DOF articulated arms, often with supplemental axes to pitch the paint gun and to traverse alongside a moving line. The potential for ignition of solvents and suspended particles may require taking precautions to eliminate ignition sources associated with the sparking of motors and other electrical components. Until brushless DC motors became commonly available for robot actuation virtually all painting robots were hydraulic because of the motor sparking problem. Lead-through teaching (also called teach-playback) is typical for painting. Off-line programming of painting is becoming more popular and some special software packages are available. [Figure 14.11.4](#) shows an image from a simulation used in validating painting robot motion programs. Some compound spraying is done with smaller general-purpose robots, for example, spraying of protective coatings in the electronics industry. Circuit boards may require unexpected dexterity in order to point the spraying nozzle correctly to coat board features.

### **Compound Dispensing**

Compound dispensing refers to laying a bead of fluid material on a surface. Application examples include caulking car bodies, sealing windshields, placing solder masking on circuit boards, gluing subassemblies,

**FIGURE 14.11.4** Painting operation simulated in off-line programming environment. Estimated paint thickness is illustrated by shading. (Courtesy of SILMA, Inc.)

solder paste dispensing, and decorating candies and cakes. Precision of placement and amount is critical. Smooth controlled paths are often essential. Position accuracy and tool path velocity accuracy are both important requirements.

All types and configurations of robots are used for dispensing. Many applications require only three DOF. When obstructions must be maneuvered around to gain access to the dispense locations, five or six DOF are needed. Payloads are usually small. Dispense speed may be limited by either the robot's ability to track a path at high speeds or by the dynamics of the dispensing process. In automotive applications the fixed cycle mode of operation is common. A robot program to lay a bead of sealer along the edge of a windshield is a taught path requiring good dynamic path repeatability of the robot. In electronic circuit board fabrication and decorating cakes, each workpiece may have a different dispense pattern; teaching paths are not practical in this situation. Some method of off-line programming must be used.

### Cutting

Many engineering materials are produced and supplied as stacked or rolled flat plates or sheets. Further fabrication can require forming and/or cutting these materials into precise shapes. Robots are frequently used to manipulate a variety of cutting tools along paths that are often complex and curved. Many cutting processes are also used to produce fine features such as holes and slots. Common robotically manipulated cutting processes are listed below.

*Laser.* Molten metal heated by collimated intense light is blown away by a gas jet. Most common use is for thinner metals (0.50 in. or less) and on a variety of other thin materials.

*Waterjet.* A high velocity water jet is formed by forcing very high pressure water through a small orifice in the range of 0.008 to 0.040 in., which can cut a variety of nonmetals.

*Abrasivejet.* After a high velocity water jet is formed it passes through an abrasive mixing chamber where abrasive particles are entrained in the jet. A variety of metals and other tough and hard materials can be precisely cut; many materials can be cut with good control up to 1.0 in. thick. Cut thickness in excess of 6.0 in. has been reported.

*Plasma Arc.* Molten metal heated by an electric arc is blown away by a gas jet. Plasma arc cutting is commonly used to cut patterns in plate steel.

*Router.* A rotary cutter is most often piloted either on the workpiece or a guide fixture for precise trimming or chamfering edges of plate and sheet material.

*Knife.* A variety of knife types, some ultrasonically assisted, are employed to cut mostly nonmetals.

The cutting tool path and pose must be precisely controlled to achieve accurately patterned piece parts. The demands on manipulator performance are primarily determined by the interaction of desired part geometry, material thickness, and material properties. Feed rate, tool stand-off, beam, jet, and arc angle are all cutting process control variables which must be adjusted to material characteristics for good results. An extreme case of cutting manipulator performance demand is the combination of thin easily cut material with complex shape, and small geometric tolerance. This requires high speed coordinated motion of five or more axes which must be kept on track. This translates to a requirement for high performance servo-control elements in order to achieve high rates of mechanical response and joint angle position and velocity precision. Some type of advanced programming method such as a CAD/CAM may be required for high part mix applications. When extreme precision and complexity are required, as in many aerospace applications, precision fixtures incorporating tool guides may be used to force the tool path to repeat with near-zero deviation. In the case of contact tools such as routers and wheel knives the end effector must be capable of bearing preload forces applied in excess of the tool reaction forces to eliminate tool bounce-induced path errors.

Equipment and tooling for many of the robotic cutting processes may be complex and expensive. End effectors can easily cost tens of thousands of dollars and require difficult and cumbersome wiring and plumbing. Routing of laser wave guides and high pressure tubing for water jets from power source to robot end effector requires skill and experience in both design and installation.

The majority of cutting robots are three-axis natural Cartesian machines specially designed to cut flat sheet materials. Cutting speed and accuracy performance are aided by their easily calculated kinematics and easily predicted dynamics. Path planning and path generation are also simplified with flat parts. CNC is commonly used, and many automatic nesting and path programming software systems are readily available. There is some use of tool position sensors for part location during setup. In-process sensor-based tracking for edge cutting has been implemented with success, but is rare. Several five-axis gantry-style machines have been implemented for cutting complex aerospace materials including impregnated broadcloth patterns and composite wing skins. Articulated arm robots may be used when less precision is needed, as in trimming automobile carpet or making cut-outs in large plastic moldings.

### **Arc Welding**

Arc welding is a metal joining process that uses intense heat produced by an electric arc between an electrode and the metal parts being welded. The weld pool and arc are always shielded by inert gas or a chemical vapor. In gas metal arc welding (sometimes called metal inert gas welding), which is the most common robotic arc welding, an electrode of filler metal wire is fed through a gun into the weld pool site as the robot manipulates the gun along the weld path. The hazards of arc welding include: intense ultraviolet, visual band and radio frequency radiation, toxic fumes, and noise. The pose (position and orientation) of the welding gun with respect to the joint or seam is a major arc control parameter. The feed rate of the gun is important in control of penetration and other weld characteristics. Unlike spot welding, manipulation is an arc welding process control variable.

Most arc welding robots operate in fixed cycle mode, which means they execute or play back a programmed sequence. If assemblies are presented to the robot with consistent seam geometry, then the path can be taught once, stored, and then executed repeatedly for each assembly. Given that all other relevant process variation is within accepted limits, the system will produce satisfactory output. However, weld seam position and seam shape variations may influence the process, especially in larger assemblies. When there is variation in the upstream sizing, cutting, fit-up, and jiggling of weld assemblies, the location and orientation of the weld seam will vary. Also, as the weld progresses, localized thermal expansion and residual stresses can force seam distortion. A range of methods for adapting the robot system to these variations exists, from correcting pretaught path plans at setup time, through actively altering robot motion in "real time." A sustained high level of academic and commercial research and development effort has resulted in practical methods of automatic weld seam tracking and process control.

Rapid deployment in recent years is a direct result of sensor integration for seam tracking. Seam tracking methods correct the path to compensate for errors in location and orientation of the welding tip based on sensor data. Commonly used sensors include mechanical probes, computer vision, laser edge detection and ranging, and arc current and voltage. Because of the extreme environment of the region surrounding an active welding tip, sensors are often housed in protective chambers. Typically the errors are measured and calculated in a convenient reference frame in the three-dimensional workspace of the robot system, the same space in which the tool path is described. In some cases the error is measured by tool-mounted sensors relative to the moving reference frame of the tool. The preprogrammed path is then shifted by mathematical transform in the reference frame of the tool. An important aspect of seam tracking is the use of sensors to detect the sides of the weld channels as boundaries for automatic side-to-side weaving. This is usually done with “through-the-arc” sensing in which arc current is monitored as an indicator of clearance between the welding tip and the channel edge. While tracking in the direction of the seam, transverse motion commands are given so that the tip approaches one edge until the edge is sensed and then the motion is commanded in the direction of the other edge. Weld penetration, filler deposit amount, and weld bead shape can be controlled in-process by variable control of the welding speed or feed rate. Arc welding robot systems which use sensors to adjust the robot path in real time (computation is fast enough to respond to sensor data with useful path adjustments) are among the most advanced or intelligent robotic applications found in practical industrial use.

Robots used for arc welding must be capable of precisely executing taught paths. Motion must be smooth and precisely controlled. Velocity control is important but the speeds required are not high, 2 in./sec, while welding is faster than most applications require. Higher velocities are important to reduce cycle time for applications with lengthy arc-off motion. Welding robots must have good reach and dexterity. Five DOF is required as a minimum and six DOF adds to gun maneuverability. There is normally no forced contact with the weld seam and the welding gun’s weight is usually less than 20 lb, so robot payload requirements are light. If real-time path altering is required, the robot’s motion generation functions must have programmable interfaces with the sensor systems. The robot’s controller must have a means of accepting data and manipulating it for use with high level functions in the robot’s native programming language.

### **Finish Machining**

Few material-forming processes produce finished parts. Most machining operations leave burrs and sharp edges. Large aircraft wing skins are milled by three-axis terrace cutting leaving small steps which must be blended to prevent fatiguing stress concentrations. Complex curved surfaces like ship propellers and aircraft landing gear are machined with rounded milling tools which leave a pattern of tool marks which must be ground off. Cast parts require gate and sprue removal and deflashing. Many parts must have their surfaces conditioned for appearance or subsequent plating and coating operations. Stamping and forging of automobile door panels and engine components leave “imperfections” which are finished out by hand. Die cast surfaces of hardware for door handles, faucets, furniture, and appliances are ground and polished. Finishing removes material to reduce waviness, reduce roughness, remove burrs and sharp edges, and to remove flaws. Manipulation is a finish machining process control variable. Tool pose, applied pressure, feed rate, and tool path must be controlled. Smaller parts are finished using fixed-floor or bench-mounted tool stands. For larger work pieces the finishing tool is mounted on the robot. Finish machining is very demanding of the manipulator because continuous path control is required while maintaining contact between part and tool.

Medium- to large-sized robots are usually required for surface finishing because end effector weight and tool reaction force are additive when calculating payloads. A further margin of payload is usually required to offset the fatiguing effects of vibration and cyclic loading from tool reactions. Tool point positioning accuracy is less important than tool orientation and feed rate. In general, higher rates of surface curvature will require greater robot path precision. Six DOF robots are often required. Edge machining tool paths are constrained by burr geometry, finishing tool characteristics, end effector geometry, and part geometry. A single part may have edge features in several directions and orientations.

The robot may require an assortment of different tools and a tool changer to reach all edges. If these measures do not allow access then multiple setups may be needed to present all features for finishing.

Most robotic surface finish machining applications use compliant abrasive processes. Force control is required in some applications to keep tool pressure constant. Force controllers are most often incorporated in the end effector or in the tool stand. Figure 14.11.5 shows a robot equipped with a force-controlled finishing end effector using a servo-controlled pneumatic actuator that is capable of applying consistent tool pressure. Through-the-arm robot force-control is available from some robot manufacturers, but its usefulness is limited to applications requiring slow feed rates because of slow mechanical response.

**FIGURE 14.11.5** Robot equipped with force-controlled end effector grinds tool marks from ship propellor. (Courtesy of The Automation and Robotics Research Institute, The University of Texas at Arlington.)

Path planning and programming of edge and surface finishing for complex-shaped parts can be very difficult and time consuming. Both tool position and tool pose are critical in obtaining the correct tool contact area. Tedious paths programmed using the teach method require hundreds of hours to develop because of the large number of taught points. Generating the path control sequence is a major problem in manufacturing operations which produce a variety of complex-shaped parts. An example is in polishing large asymmetric-shaped aircraft skin panels. A more difficult automation problem is robotic spot finishing of flaws and other anomalous regions of the part surface when their location and extent are not known before set-up time. The reason is that the paths must be planned, generated, and executed on-line. This type of motion generation system requires part modeling and computational functions not available on most robot controllers. Figure 14.11.6 shows an operator digitizing a part surface to be modeled in preparation for automatic path generation by the PC.

## 14.12 Mobile, Flexible-Link, and Parallel-Link Robots

---

*Kai Liu*

This section will discuss nonstandard robots, including mobile robots, lightweight flexible-link robots, and parallel-link robots. These robots are often more suitable than standard serial-link commercial robots for certain applications.

### Mobile Robots

Traditionally, standard robots are fixed in position. They are mounted on a rigid base and bolted to the floor so that they can withstand the forces and torques applied when the arm manipulates objects. However, fixed-base robots cannot cope with a large variety of applications in which a robot will operate in large and unstructured domains. A special type of manipulator, that is, a mobile robot, is often required in these applications.

In tomorrow's flexible manufacturing system (FMS) environment, mobile robots will play an important role. They will transport parts from one workstation to others, load and unload parts, remove undesired objects from floors, and so on. In addition to indoor mobile robots, there are some other outdoor occasions where mobile robots may take on heavy responsibilities. Examples include construction automation, military missions, handling of harmful materials, hazardous environments, interplanetary exploration, and so on.

### Classifications of Mobile Robots

Mobile robots can be classified by driving mechanism as wheeled mobile robots, legged mobile robots, and treaded mobile robots. Some other types of mobile robots, for instance, the *underwater mobile robots*, the *autonomous aerial mobile vehicle*, and so on, are also available but are not included in this discussion.

*Wheeled Mobile Robots.* Mobile robots using wheels for locomotion are called *wheeled robots*. Two driving configurations are used in today's wheeled mobile robot — steer-drive and differential-drive. The former uses two driving wheels to make the vehicle move forward and backward. The heading angle is controlled by an independent steering mechanism. Since the driving action is independent of the steering action, the motion control of the vehicle is somewhat simplified. However, due to physical constraints, this configuration cannot turn in a very small radius. This shortcoming makes it less attractive in some industrial applications. Differential-drive configuration mobile robots, on the other hand, have two independent driving wheels positioned at opposite sides of a cart base, arranged parallel to one another. Their speeds can be controlled separately. Thus, by appropriately controlling the speed of each driving wheel, this mechanism is able to drive the vehicle forward and backward, as well as steer its heading angle by differential speed commands. Even though this configuration requires a somewhat more complex control strategy than the steer-drive configuration, its capability of making small-radius turns, even making turns on-the-spot, makes it the first choice in many industrial applications.

Some commercial wheeled mobile robots include the *CyberGuard Autonomous Surveillance Robot* manufactured by Cyberworks Inc., Canada; *B12 Mobile Robot Base* manufactured by Real World Interface, Inc., Dublin, NH; *LabMate Mobile Robot Platform* manufactured by Transitions Research Corporation, Danbury, CT; and *R-20 Mobile Robot* manufactured by Arrick Robotics, Euless, TX.

*Legged Mobile Robots.* While most mobile robots use wheels for locomotion because of the simplicity of the moving mechanism design and control, some other mobile robots use legs for locomotion. These types of mobile robots are called *legged robots*. The primary advantages of legged robots include their ability to traverse rough terrain with good body stability and minimal ecological damage. In order to maintain good stability, it is sufficient that at any time there are three points in contact with the ground. Therefore, most legged robots use at least four legs, or even six or eight legs. As long as the legged mobile robots' center of gravity is within the triangle formed by the three contact points, stability is

guaranteed. Compared with the wheeled robots, the control of legged robots is much more difficult. Much has been learned about multilegged locomotion from studies of balancing and hopping on a single leg. In particular, biped running can be viewed as successive hopping on alternating legs, since both legs never contact the ground simultaneously. Some examples of legged mobile robots include *ODEX I* manufactured by Odetics.

*Treaded Mobile Robots.* Another type of mobile robot, the treaded robot, moves much like a tank. An example of the treaded robot is the *ANDROS MARK V* manufactured by REMOTEC, Inc. at Oak Ridge, TN. It is something of a hybrid between a walking and a rolling vehicle. *ANDROS* can ascend/descend 45° stair/slopes by lowering its front and rear auxiliary tracks. It has all-terrain capabilities that are ideal for performing missions in rough outside terrain or in rubble-strewn, damaged buildings.

## Sensors and Measurements

To navigate in unknown and unstructured areas, the mobile robot must have the capability of sensing the real world, extracting any useful information from the data acquired, and interpreting the information to understand the environment surrounding it, especially the situation in front of it. Several sensor systems for mobile robot navigation have been reported in the literature (Elfes, 1987). Of these, stereo vision systems and active rangefinding devices are the most used sensor systems. The former extracts range information from pairs of images to build a 3D world map. However, due to the high computational expense — a 3D map may require 1 min to generate — stereo vision systems have not to date been generally used for real-time navigation control. Active rangefinding devices do not suffer from this problem because they can deliver range information directly

Two kinds of rangefinding devices are available: laser rangefinders and ultrasonic range transducers. Even though laser rangefinders can provide fast response with high resolution, a relatively long measurement range, and high measurement precision, the required systems structure and configurations are very complicated, which makes the system itself very expensive. On the other hand, sonar systems are simple and low cost (probably orders of magnitude less expensive than laser-based systems), though the measurements have lower resolution and lower precision.

Determining range by means of sonar systems is a simple process. A short burst of ultrasonic sound is first transmitted by an ultrasonic range transducer, then an echo is expected to be received by the same transducer. If in a reasonable time period no reflected signal is detected, it is assumed that there are no objects in the area of interest. Otherwise, the time for round-trip propagation is determined and the distances to any objects are calculated. The transducer yields a 3-dB full angle beamwidth of 50 KHz at approximately 12 to 15°, depending on the signal frequency and transducer diameter. Thus, to scan the whole area surrounding the mobile robot, at least 24 to 30 transducers, of which the transmit/receive axis lies in the same horizontal plane, are needed.

Vision systems, also sometimes useful in robot sensing, usually consist of one or more video cameras and an image processor. The vision system can provide the richest source of information, which is, in fact, needed in certain applications such as road following, object identification, and so on.

Feedback from rotary and linear actuators used in wheeled and/or legged mobile robots is provided by position sensors and/or velocity sensors. This information is then processed for estimating position and orientation of the mobile robot in world coordinates.

By far the most commonly used position sensor is the *optical encoder*, which uses marks to indicate position. The typical encoder has a track for each binary digit of information. The encoder is mounted on the servo motor. When the motor rotates certain degrees, the absolute rotation position of the axis can be read from the digital output of the encoder. The resolution of the encoder is equal to  $(360/2^n)$  degree, where  $n$  is the number of tracks. If an 8-track encoder is used, then a 1.4°/step resolution can be attained.

Other types of position sensors used in mobile robot systems include synchros, resolvers, potentiometers, linear variable differential transformers (LVDT), rotary variable differential transformers (RVDT), amplitude-modulated laser radars, and laser interferometers.

Conventional servo design requires that the servo controller include a “velocity term” in its transfer function. Without the velocity term, a servo system will usually exhibit an undamped, resonant behavior and can be highly unstable. In principle, the signal from a joint position sensor can be electronically differentiated to obtain joint velocity. However, if the joint position sensor has a noisy output, differentiating the position sensor signal can effectively magnify the noise sufficiently to make the servo system unstable or unreliable. To overcome this difficulty, several velocity sensors are available for directly measuring the joint velocity. A *DC tachometer* system consists of a voltage meter (or a current meter) and a small DC generator (sometimes called a “speed-measurement generator”). The latter is usually constructed with a permanent-magnet stator and a multipole wound armature. The armature is connected directly to the rotating shaft of the servo motor which is used to drive the manipulator joint. When the small permanent magnet DC generator rotates with the servo motor, its output voltage (when driving a high-impedance load) varies in proportion to the rotation speed of the armature. Voltage output variations can then be translated into speed changes or used as a feedback signal to control the robot arm velocity.

Supplementary position and orientation information can also be supplied by inertial guidance sensors, terrestrial magnetic field sensors, or inertial reference systems (IRS).

### Navigation

Autonomous navigation of mobile vehicles has been studied by many researchers. In Elfes (1987), a sonar-based navigation system for an autonomous mobile robot working in unknown and unstructured environments was developed. The workspace is classified into “probably empty regions,” “somewhere occupied regions,” and “unknown regions” based on the interpretation of the data obtained from the sonar system. In this scheme, as more and more data are received, the first two regions may increase, and the uncertainty of these regions also decreases. It is reported that after a few hundred readings, a sonar map covering a thousand square feet with up to 0.1-ft position accuracy can be made. Another navigation scheme uses a stereo vision system to control a mobile base autonomously operating in a complex, dynamical, and previously unknown environment. A pair of stereo cameras is mounted on the mobile base to generate a symbolic world model. Based on this model, the desired trajectories are specified for the driving motors.

Although the schemes described above work well in specific environments, path planning and navigation control are always separated into two isolated issues. The path planning mechanism designs a smooth path from an initial position to a goal position by providing profiles of position and velocity, or profiles of position and heading angles, in Cartesian space. It assumes that perfect knowledge of the system dynamics and the environments is always available and that the position and orientation of the vehicle are measurable absolutely. After the desired trajectories have been designed, the navigation mechanism will take charge of driving the mobile robot to follow the prescribed trajectory as closely as possible. Even though each mechanism may work well through closed-loop control, the whole navigation system is an open-loop system. Static path planning strategies do not provide the essential adaptability necessary for coping with unexpected events. The success of navigation control depends mostly on the accuracy of absolute measurements of position, velocity, orientation, and their rates of change. All of these must be measured in (or transformed to) Cartesian space. This is a very expensive and difficult job.

Other possible closed-loop navigation control schemes use intelligent control techniques, for instance, fuzzy-logic control. In such a control scheme, the path-planning mechanism and trajectory-following mechanism are often integrated, not separated. The path is planned dynamically and is always up-to-date. All the information that the system needs to know such as “where is the goal (the dock),” “what is the required final orientation (the docking angle),” “what is the present orientation (the present heading angle),” “what is the present distance between the car and the goal,” “what is the present distance between the car and any obstacles,” “what is the safe turning radius (the minimum curvature radius),” and so on is easily captured through sensing the environment surrounding the car using onboard sensors (e.g., sonar) that yield relative information.

The advantages of such intelligent control strategies are evident. They unite navigation and maneuvering into a single set of algorithms. Full and accurate knowledge of the system dynamics is not required. The only knowledge needed are the correlations between the control actions (acceleration, steering, etc.) and the performance (“behaviors”) of the system. The absolute measurement of the position and velocity in Cartesian space is not required. Only information about relative locations is necessary, and this is always available. Tight coupling between sensor data and control actions provides the adaptability necessary for coping with unexpected events. Actually, there is no path planning to be performed; the driving mechanism reacts immediately to perceived sensor data as the mobile robot navigates through the world.

### Flexible-Link Robot Manipulators

Most robots used in today’s manufacturing systems are rigid-link manipulators. Making the **robot links** and drives extremely stiff to minimize vibrations allows rigid-link robots to track a desired trajectory with very high degree of accuracy, often using standard classical (PID) control schemes. However, the price paid for this includes heavy manipulators, a low payload-weight-to-arm-weight ratio, high power consumption, and slow response rates to motion control commands.

With the growing demand from industry automation for lower manufacturing costs, higher motion speeds, better performance, and easier transportation and setup, the rigid-link manipulators may, sooner or later, be replaced by some sort of lightweight mechanical structures, such as flexible-link robots. While lightweight flexible manipulators have certain inherent advantages over rigid-link robots, they impose more stringent requirements on system modeling and controller design because of the vibrations of the flexible modes.

### Modeling of Flexible-Link Robots

One essential step toward successful control synthesis is to obtain an accurate dynamic model for flexible-link manipulators. The flexible manipulator dynamics can be derived on the basis of a recursive Lagrangian assumed-modes method (Book, 1984). The motion of robots with link flexibility is governed by partial differential equations that must be satisfied inside a given domain defining the flexible structure, and by boundary conditions to be satisfied at points bounding this domain. Therefore, the dynamic model of flexible-link manipulators consists of highly coupled nonlinear integro-partial differential equations. Control of a structure using a formulation based on partial differential equations is extremely difficult. To reduce the complexity of the model, the assumed-modes method is used to produce a set of nonlinear ordinary differential equations based on an orthonormal series expansion of the flexure variables.

A solution to the flexible motion of links is obtained through a truncated modal approximation, under the assumption of small deflections of the links. The dynamic equations of motion for an  $n$ -degree-of-freedom manipulator with up to  $m$  flexible links can be written as

$$\mathbf{M}(\mathbf{q}, \delta) \begin{bmatrix} \ddot{\mathbf{q}} \\ \ddot{\delta} \end{bmatrix} + \mathbf{D}(\mathbf{q}, \dot{\mathbf{q}}, \delta, \dot{\delta}) \begin{bmatrix} \dot{\mathbf{q}} \\ \dot{\delta} \end{bmatrix} + \begin{bmatrix} 0 & 0 \\ 0 & \mathbf{K}_f \end{bmatrix} \begin{bmatrix} \mathbf{q} \\ \delta \end{bmatrix} + \begin{bmatrix} \mathbf{F}_r(\mathbf{q}, \dot{\mathbf{q}}) \\ 0 \end{bmatrix} + \begin{bmatrix} \mathbf{G}_r(\mathbf{q}) \\ 0 \end{bmatrix} = \begin{bmatrix} \mathbf{I} \\ \mathbf{B}_f \end{bmatrix} \tau$$

where  $\mathbf{q} = [q_1 \ q_2 \ \dots \ q_n]^T$  is the vector of rigid joint variables,  $\delta = [\delta_1 \ \delta_2 \ \dots \ \delta_m]^T$  is the vector of deflection variables,  $\mathbf{M}(\mathbf{q}, \delta) \in R^{(n+m) \times (n+m)}$  is the inertia matrix,  $\mathbf{D}(\mathbf{q}, \dot{\mathbf{q}}, \delta, \dot{\delta}) \in R^{(n+m) \times (n+m)}$  contains both rigid and flexible coriolis/centripetal terms and terms representing the interactions of the joint rigid variables with the deflections,  $\mathbf{K}_f \in R^{m \times m}$  is the stiffness matrix,  $\mathbf{F}_r(\mathbf{q}, \dot{\mathbf{q}}) \in R^n$  is the friction, and  $\mathbf{G}_r(\mathbf{q}) \in R^n$  is the gravity term. The control input is  $\tau \in R^n$  and the input matrix  $[\mathbf{I} \ \mathbf{B}_f]^T \in R^{(n+m) \times n}$  is generally a function of  $(\mathbf{q}, \delta)$  depending on the boundary conditions (e.g., pinned-pinned, pinned-free, clamped-free) chosen by the designer. Note that the coriolis/centripetal matrix  $\mathbf{D}(\mathbf{q}, \dot{\mathbf{q}}, \delta, \dot{\delta})$  can take several different definitions. However, among these definitions, there exists one such that the derivative of the inertia matrix  $\mathbf{M}(\mathbf{q}, \delta)$  and the coriolis/centripetal matrix are related in a very particular way, that is,  $\dot{\mathbf{M}}(\mathbf{q}, \delta) - 2 \mathbf{D}(\mathbf{q}, \dot{\mathbf{q}}, \delta, \dot{\delta})$  is *skew symmetric*, a property that is often very useful for controls design.

It is important to realize that the rank of the control effectiveness matrix  $\text{rank}([\mathbf{I} \ \mathbf{B}_f]^T)$  is less than  $(n + m)$ , that is,  $\text{rank}([\mathbf{I} \ \mathbf{B}_f]^T) = n < (n + m)$ . This means that the number of degrees of freedom is greater than the number of control inputs and is the major source of the problems in controlling flexible-link manipulators.

### Control of Flexible-Link Robots

Control of mechanical manipulators to maintain accurate position and velocity is an important problem. Rigid-link manipulators are designed to be mechanically stiff precisely because of the difficulty of controlling flexible members. The major objectives in control of a robotic system with link flexibility are to command the tip of the flexible-link manipulator to move from one position to another as quickly as possible (point-to-point minimum-time control), or to follow preplanned desired trajectories (trajectory-following control) while keeping the oscillations of the flexible modes as small as possible. The inherent large nonlinearities of flexible-link manipulators make their control very difficult. The link flexibility makes the robot arm itself sensitive to external excitation; a small impulse signal may cause the flexible modes to oscillate wildly.

Several conventional control techniques have been studied by robotics researchers for the control of flexible-link manipulators. They fall into different categories. The first category includes some approximate techniques such as linear systems approaches, linear minimum-time control, decentralized approaches, and input-shaping techniques. Conventional control techniques cannot usually obtain very satisfactory results for fast desired motions.

The second category includes some new control approaches that take into account many of the nonlinearities. Among them are variable structure control, adaptive control, and the inverse dynamics approach (where the whole control signal is composed of a causal part and an anticausal part). To minimize residual vibrations, several constraints must be applied for the desired tip trajectories. As pointed out in Kwon and Book (1990), for a specified rigid mode trajectory, there is associated a unique flexible mode trajectory. The interactions between the desired rigid motion and the associated required flexible motion (e.g., the inverse dynamics) are very complicated and parametrically sensitive.

Since the number of independent control inputs is less than the number of the output variables in the case of flexible-link arms, the control problem is characterized as having *reduced control effectiveness*. The so-called “model matching conditions” do not hold, and the conventional control techniques usually used in the control of rigid-link robots (e.g., computed-torque control) cannot be directly applied to the control of flexible-link arm. This problem can be solved by a model-order reduction based on a singular perturbation strategy, in which the rigid modes are treated as slow-state variables, while the flexible modes and their time derivatives are treated as fast-state variables. Another approach is the “reduced-order computed torque scheme” that first removes the nonlinearities that are in the range of the control input matrix, then uses PD state-feedback loop to convert the flexible system to a set of uncoupled point-mass-like systems.

A third category of controllers includes various intelligent control schemes such as neural networks (NN) (Lewis et al., 1995) and fuzzy logic control (FLC). Many of the drawbacks mentioned above can be overcome by either FLC or NN control if these are used in conjunction with sound control engineering design practices (e.g., singular perturbation and/or feedback linearization techniques). The reason is obvious: FLC and NN are *model-free* control schemes applicable to a wide range of dynamical systems that are ill understood and ill defined. The primary reason for this model-free characteristic is the ‘universal approximation property, shared by NN and FLC. Thus, by careful design, effective control actions can be generated without extended analyses based on a precise, explicit mathematical function.

### Parallel-Link Robots

By far the most widely used commercial robots are the serial-link manipulators, whose links and joints alternate with one another in an open kinematic chain. This serially connected configuration is similar to that of the human arm, with each link connecting only to two neighboring links through either prismatic

or revolute joints, except for the last link which attaches to the end effector and the robot base which attaches to the floor. The advantage of the serial chain structural arrangement is that it provides a large work volume and dexterous manipulability; however, it suffers from a lack of rigidity and from accumulated actuator errors. Especially at high speed and high dynamic loading operating conditions, the serial-link manipulators show poor dynamic performance. To improve the dynamic performance and achieve high precision operations, the robot links must be made with high rigidity, which results in heavy robots with low force-output-to-manipulator-weight ratio. On the other hand, if the links can be arranged parallel to one another in a closed kinematic chain structure such that the major force components add together, then high precision operations and high force-output-to-manipulator-weight ratios can be achieved.

### The Stewart Platform

The most popular and successful parallel mechanical structure is the so-called Stewart platform, which was first proposed by Stewart (1965) in 1965. As a manufacturing manipulator, the Stewart platform has two fundamental characteristics which set it apart from machine tools and industrial robots — it is a *closed kinematic system with parallel links*. The Stewart platform link ends are simply supported, making the manipulator system far more rigid in proportion to size and weight than any serial link robot. Furthermore, the links of the Stewart platform are arranged so that the major force components of the six actuators add together, yielding a force-output-to-manipulator-weight ratio more than one order of magnitude greater than most industrial robots.

The original Stewart platform was designed for an aircraft simulator and consisted of six linear hydraulic actuators acting in parallel between the base and the upper platform, as shown in [Figure 14.12.1](#). All the links are connected both at the base and at the upper platform. Thus, by changing the length of each link, the position and orientation of the upper platform are able to be controlled.

**FIGURE 14.12.1** A six-degree-of-freedom *Stewart platform manipulator* developed at the Automation & Robotics Research Institute, The University of Texas at Arlington.

Some nice features of the original Stewart platform include:

- The manipulator design has six degrees of freedom, three for position and three for orientation.
- The six linear actuators are driven by six motors with each motor reacting on the base to avoid interaction between motors. Actually the manipulator can move when five of the jacks are locked merely by adjustment of the remaining jack.
- To achieve the maximum performance for a given power source, each motor operates directly on the same load (the upper platform). This makes a high payload-to-structure-weight ratio that at certain points of the workspace amounts to nearly six times the lifting capability of each individual actuator.
- Having low friction losses, with a powerful hydraulic system the manipulator can respond to commands very quickly.

It is interesting to note that the Stewart platform was not the first parallel link mechanical structure used in industry. As early as the 1950s, McGough devised a similar device for studying tire-to-ground forces and movements. The system had been in operation since 1955, but was never made known to the public until 1965 when Stewart published his journal article.

### **Advantages and Problems of the Stewart Platform**

The Stewart platform appears simple and refined to the point of elegance. The performance mentioned above can be achieved using relatively inexpensive commercially available servo-actuator technology. The Stewart platform uses a closed kinematic chain which is structurally extremely strong and rigid, and is capable of distributing loads throughout the system. The actuator errors are not cumulative, allowing for high precision operations. However, the same closed kinematic structure that provides mechanical stiffness also complicates the forward kinematics analysis. This problem is an impediment to the derivation of dynamic equations and hence control schemes for real-time trajectory generation, which is necessary for industrial application of the manipulator (e.g., surface finishing applications).

It is known that in the case of fully parallel structures, the inverse kinematics (that is, solving for the corresponding lengths of the links given the position and orientation of the upper platform in Cartesian space) is relatively straightforward. However, the forward kinematics analysis for the fully parallel mechanism (e.g., given the length of each link, solve for the position and orientation of the upper platform in Cartesian space) is very challenging. The reason is that the kinematic equations are highly coupled and highly nonlinear.

Much effort has been devoted to finding an efficient algorithm for computing an accurate kinematic solution. To solve for the Cartesian position of the upper platform in terms of the given link lengths, thirty (30) nonlinear algebraic equations must be solved simultaneously, or polynomials of order 16 in a single variable must be solved. Due to the time-consuming nature of these procedures, it is difficult to compute the kinematic solutions on-line in real time. In Liu et al. (1993), a simplified algorithm was proposed which required to solve for only three (3) simultaneous nonlinear algebraic equations. Since the Stewart platform requires complex kinematics computations for trajectory following control, it is difficult to achieve real-time control capable of supporting high bandwidth motion.

The common feature of the forward kinematics analyses mentioned above is that there is no explicit analytical solution. Even for Liu et al.'s algorithm, it is still required to solve three nonlinear algebraic equations by numerical methods. Since there is no explicit expression available for the forward kinematics, deriving the Jacobian matrix and dynamic equations directly in link space and studying the singularity become impossible.

It is known that the Jacobian provides a transformation path which allows a two-way transformation between the link space and Cartesian space. If the Jacobian is not singular, then velocity in link space can be uniquely transformed to the corresponding velocity in Cartesian space. Particularly, if there is no movement in link space, then there is no movement in Cartesian space, so that the Stewart platform will remain rigidly fixed. However, at singular configurations, the transformation path from link space

to Cartesian space is blocked. In this case, even though there is no movement in link space, the upper platform can lose rigidity, still possibly moving along some directions. In other words, at singularities, the Stewart platform may gain extra degrees of freedom. The problem becomes even worse in that, in this situation, forces or torques in Cartesian space cannot be transformed to link space, that is, at singular positions the Stewart platform cannot be controlled to move in all directions and cannot exert force in all directions. From the applications viewpoint, investigating the conditions under which there will be singularities is important.

Thus, while the parallel link manipulators afford structural advantages, they also present severe difficulties for controller design. The control problems associated with such structures are not easy, as the systems do not satisfy most of the assumptions made in the controls literature (e.g., linearity in the parameters and feedback linearizability). Therefore, most existing control algorithms do not work well.

### Manufacturing Applications of the Stewart Platform

Since proposed by Stewart (1965) in 1965, various applications of the Stewart platform have been investigated for use as aircraft simulators, as robot wrists, in mechanized assembly, and in active vibration control. As a manufacturing manipulator, the Stewart platform has great potential in automating many light machining applications such as surface finishing, edge finishing, routing, and profile milling. New manipulator applications to manufacturing processes requiring high force and power output such as combined assembly pressing are also possible. There are several light machining applications that a Stewart platform manipulator would perform with less set-up complexity and tooling cost than a serial link robot or a standard machine tool. In [Figure 14.12.2](#) is shown a Stewart platform developed as a surface finishing milling machine.

**FIGURE 14.12.2** Stewart platform automated surface finishing cell.

Many applications of robotic manipulators to high precision routing can be found in the aerospace industry. A common application is trimming wing skin edges. The precision is usually achieved through the employment of expensive templates that provide a precise guide bearing for the tool to follow as it is held in the naturally compliant grip of a robotic manipulator. The major advantage for using a Stewart platform as a routing machine is that it can follow the contours of many aerospace parts without the

need for a tool guide; it is stiff enough to track the part precisely while withstanding the router cutting reactions. The cost of this contouring capability as compared to a standard five- or six-axis routing machine would be much lower.

The Stewart platform would be superior to any serial link robot as a drilling head manipulator. Virtually all applications of drilling robots in aerospace manufacturing require the use of expensive and complex end effectors or part jigs to compensate for the inaccuracy and lack of stiffness of the robots. Drilling jigs for some parts can cost as much as ten times more than the robot itself. Special end effectors are often used to apply preloads to prevent the drill from “walking” and chattering. The Stewart platform could perform many drilling tasks unaided by special tooling because of its stiffness and precision.

The industrial robot has generally not been considered to be a good milling manipulator. The Stewart platform could potentially perform contour milling of some materials with near-machine-tool accuracy. A Stewart platform milling machine with stiffness and dexterity characteristics intermediate between a large serial link robot and a five-axis mill could be built at or below the cost of a commercial serial link robot. A Stewart platform milling machine successfully used for industrial applications is shown in Figure 14.12.2.

When a direct contact tool like a grinder is used it is important to control both the tool position and the forces involved so that the substrate is not damaged. For example, when grinding mold scale a very aggressive tool may be needed, and the normal force applied can be as large as 40 to 50 lbs so long as the penetration into the surface is precisely controlled. The reactions in the surface tangent plane can be very large and could cause oscillations if not held rigidly. A Stewart platform with a constant force suspension for its tool could apply very large force with very high stiffness in one direction while being compliant and forceful in the normal direction.

## Defining Terms

---

**Accuracy.** The degree to which the actual and commanded positions (of, e.g., a robot manipulator) correspond for computed as opposed to taught positions.

**Adaptive Control.** A large class of control algorithms where the controller has its own internal dynamics and so is capable of learning the unknown dynamics of the robot arm, thus improving performance over time.

**AML.** A Manufacturing Language — a robot programming language.

**APT.** Automatic Programming of Tools — a robot programming language.

**Cell Decomposition.** An approach to path planning where the obstacles are modeled as polygons and the free space is decomposed into cells such that a straight line path can be generated between any two points in a cell.

**Compliance.** The inverse of “stiffness” — useful in end effectors tooling whenever a robot must interact with rigid constraints in the environment.

**Computed-Torque Control.** An important and large class of robot arm controller algorithms that relies on subtracting out some or most of the dynamical nonlinearities using feedforward compensation terms including, e.g., gravity, friction, coriolis, and desired acceleration feedforward.

**End Effector:** Portion of robot (typically at end of chain of links) designed to contact world:

- **Compound.** A cluster of multiple end effectors and tooling mounted on the robot wrist.
- **Active.** An end effector with sensing and servo control of the grasp forces and/or finger motions.
- **Prehensile.** An end effector that holds parts between fingertips or encircled by fingers.
- **Vacuum.** A nonprehensile end effector that uses suction cups to hold parts.
- **Dextrous.** A hand with the ability to manipulate parts in the fingers and actively control grasp forces.

**Feedback Linearization.** A modern approach to robot arm control that formalizes computed-torque control mathematically, allowing formal proofs of stability and design of advanced algorithms using Lyapunov and other techniques.

**Flexible-Link Robot.** Lightweight mechanical structures where vibration and flexibility of the links must be taken into account in controller design. They possess favorable features including lower manufacturing costs, higher motion speeds, better performance, and easier transportation and setup.

**Force Control.** A class of algorithms allowing control over the force applied by a robot arm, often in a direction normal to a prescribed surface while the position trajectory is controlled in the plane of the surface.

**Forward Kinematics.** Identification of task coordinates given configuration.

**Fuzzy Logic Control.** A multilevel logic controller, which is different from the conventional dual (two-level) logic in which only two values (true and false) may be assigned to each state variable. Fuzzy logic controllers have advantages in being robust to disturbances and not requiring an explicit mathematical model for the design process. They consist of three parts: the fuzzifier, the rulebase, and the defuzzifier.

**Grasp Isotropy.** A measure of how uniformly forces and motions can be controlled in different directions.

**IGES.** International Graphics Exchange Specification — a data exchange standard.

**Inverse Kinematics.** Identification of possible configurations given task coordinates.

**I/O Device.** Input/output device — a port through which external information is connected to a computer. I/O devices may be A/D, which converts analog signals to digital, D/A, which converts digital signals to analog, or binary, which passes digital signals.

**Joint Variables.** Scalars specifying position of each joint — one for each degree of freedom.

**Kitting.** The process of taking parts from bulk and placing them on a *kit tray*, which is an organized group of all parts required to assemble a single product or subassembly.

**Learning Control.** A class of control algorithms for repetitive motion applications (e.g., spray painting) where information on the errors during one run is used to improve performance during the next run.

**Linearity in the Parameters.** A property of the robot arm dynamics, important in controller design, where the nonlinearities are linear in the unknown parameters such as unknown masses and friction coefficients.

**Manipulator Jacobian.** Matrix relating joint velocities to task coordinate velocities - configuration dependent.

**Mechanical Part Feeders.** Mechanical devices for feeding parts to a robot with a specified frequency and orientation. They are classified as vibratory bowl feeders, vibratory belt feeders, and programmable belt feeders.

**Mobile Robot.** A special type of manipulator which is not bolted to the floor but can move. Based on different driving mechanisms, mobile robots can be further classified as wheeled mobile robots, legged mobile robots, treaded mobile robots, underwater mobile robots, and aerial vehicles.

**Path Planning.** The process of finding a continuous path from an initial robot configuration to a goal configuration without collision.

**PD-Gravity Control.** A special case of computed-torque control where there is a PD outer control loop plus a gravity compensation inner control loop that makes the DC values of the tracking errors equal to zero.

**Pinch Grasp.** A grasp in which a part is clamped between fingertips.

**Pixel.** Picture element — one point of an image matrix in image processing terminology.

**Prismatic Joint.** Sliding robot joint which produces relative translation of the connected links.

**Redundant Manipulator.** Manipulator for which the number of joint variables is greater than the number of task coordinates.

**Remote-Center Compliance (RCC).** A compliant wrist or end effector designed so that task-related forces and moments produce deflections with a one-to-one correspondence (i.e., without side effects). This property simplifies programming of assembly and related tasks.

**Revolute Joint.** Rotary robot joint producing relative rotation of the connected links.

**Robot Axis.** A direction of travel or rotation usually associated with a degree of freedom of motion.

**Robot Joint.** A mechanism which connects the structural links of a robot manipulator together while allowing relative motion.

**Robot Link.** The rigid structural elements of a robot manipulator that are joined to form an arm.

**Robust Control.** A large class of control algorithms where the controller is generally nondynamic, but contains information on the maximum possible modeling uncertainties so that the tracking errors are kept small, often at the expense of large control effort. The tracking performance does not improve over time so the errors never go to zero.

**SCARA.** Selectively compliant assembly robot arm.

**SET.** (Specification for Exchange of Text) — a data exchange standard.

**Singularity.** Configuration for which the manipulator jacobian has less than full rank.

**Skew Symmetry.** A property of the dynamics of rigid-link robot arms, important in controller design, stating that  $\dot{M} - \frac{1}{2}V_m$  is skew symmetric, with  $M$  the inertia matrix and  $V_m$  the coriolis/centripetal matrix. This is equivalent to stating that the internal forces do no work.

**Stewart Platform Manipulator.** A special type of parallel-link robot consisting of six identical linear actuators in parallel, an upper platform, and a base. One end of each actuator connects to the base, and the other to the upper platform with two- or three-degrees-of-freedom joints. This manipulator has a greater force-to-weight ratio and finer positioning accuracy than any commercial serial-link robot.

**Task Coordinates.** Variables in a frame most suited to describing the task to be performed by manipulator.

**VDAFS.** (Virtual Data Acquisition and File Specification) — a data exchange standard.

**Visibility Graph.** A road map approach to path planning where the obstacles are modeled as polygons. The visibility graph has nodes given by the vertices of the polygons, the initial point, and the goal point. The links are straight line segments connecting the nodes without intersecting any obstacles.

**Voronoi Diagram.** A road map approach to path planning where the obstacles are modeled as polygons. The Voronoi diagram consists of line having an equal distance from adjacent obstacles; it is composed of straight lines and parabolas.

**Wrap Grasp.** A grasp in which fingers envelope a part, to sustain greater loads.

## 16.1 Introduction

---

### Environmental Engineering and the Role of Mechanical Engineers

*Ari Rabl and Jan F. Kreider*

The subject of environmental science and management is vast and interdisciplinary, ranging from highly technical matters such as the design of emission control equipment to socioeconomic matters such as the valuation of the impacts of pollution. The goal is to prevent or reduce undesirable impacts of human activities on the environment. Within this endeavor there are several different areas where mechanical engineers can make important contributions. One type of contribution concerns the design of equipment, in particular for the control of emissions; an example is an electrostatic precipitator to reduce emissions of particulates from the flue gas of a boiler or furnace. Another type of contribution concerns the modeling of the dispersion of pollutants in the environment. This chapter covers air pollution, surface water pollution, and groundwater pollution. Since space is limited and since mechanical engineers are most likely to be involved in air pollution analysis and abatement projects, the emphasis is on air pollution problems.

## Environmental Burdens and Impacts

*Ari Rabl*

As general guidance to the field of environmental engineering, it may be helpful to present the most important environmental burdens and impacts in the form of a matrix, as in [Figure 16.1.1](#). Burdens, e.g., the emission of a pollutant, are listed in the column on the left; impact categories are listed as a row at the top. Each element in this matrix corresponds to a specific impact of a specific burden. An X indicates that the impact from the corresponding burden is likely to be significant. Particulate air pollution, for instance, has been shown to cause a significant increase in mortality.

As an added feature we have indicated the spatial and temporal extent to the burdens. The classic air pollutants (particulates, NO<sub>x</sub>, and SO<sub>x</sub>) are dispersed over distances on the order of a thousand kilometers, and they affect essentially only the present generation; thus, the second and third columns show the letters R (for regional) and P (for present generation). [Global warming](#) from [greenhouse gases](#), on the other hand, affects the entire globe and will persist over decades or centuries, hence the letters G (for global) and P, F (for present and future generations).

The classification in [Figure 16.1.1](#) is not without ambiguities or problems. For example, we have indicated the impact of greenhouse gases as “climate change” only, even though this category includes such effects as deaths from flooding. The relative importance of impacts may change with improved scientific understanding and with the evolution of societal preferences. One should also note that the assignment of effects to causes is in many cases quite uncertain; for instance, the observed mortality from air pollution could be due to particulates or due to SO<sub>2</sub>.

Some impacts, especially thermal pollution and noise, can be highly site dependent. The cooling water from a power plant, for instance, could damage the ecosystem of a river or it could be used to improve the output of a fishery.

Each of the categories in [Figure 16.1.1](#) could be broken down into subcategories:

- Health
  - Mortality
  - Injury
  - Cancer
  - Respiratory illness
- Natural environment
  - Recreational value of land (including forests)
  - Recreational value of water (including fishing)
  - Biodiversity
- Agricultural environment
  - Crops
  - Cattle (milk, meat, fur, ...)
  - Wood production by forests
  - Commercial fishing
- Man-made environment
  - Functional buildings
  - Historical buildings
  - Other objects (bridges, cars, ...)
  - Noise

Burdens	Impacts						
	Extent		Climate	Health	Environment		
	Space	Time			Natural	Agricultural	Man-Made
<b>Primary air-pollutants</b>							
CO <sub>2</sub>	G	P, F	X				
CH <sub>4</sub>	G	P, F	X				
Other greenhouse gases	G	P, F	X				
Particulates	R	P		X			X
SO <sub>2</sub>	R	P		X	X	X	X
NO <sub>x</sub>	R	P		X	X	X	X
CO	R	P		X			
Heavy metals (Pb, Hg, Cd, ...)	R	P, F		X	X		
Toxic organic compounds (e.g., dioxins)	R	P, F		X	X		
VOC (volatile organic compounds, etc.)	R	P		X			
<b>Secondary air pollutants</b>							
O <sub>3</sub> (from NO + VOC)	R	P	X	X	X		
Acid rain (from NO <sub>x</sub> , SO <sub>x</sub> )	R	P		X	X	X	X
Aerosols (from NO <sub>x</sub> , SO <sub>x</sub> , etc.)	R	P	X	X	X	X	X
<b>Liquid residues</b>							
Heavy metals (Pb, Hg, Cd, ...)	L, R	P, F		X	X		
Toxic organic compounds (e.g., dioxins)	L, R	P, F		X	X		
COD (chemical oxygen demand)	L, R	P, F		X	X	X	
BOD (biological oxygen demand)	L, R	P, F		X	X	X	
<b>Solid residues</b>							
	L	P, F		X	X	X	
<b>Other</b>							
Thermal	L	P			X		
Noise, odor	L	P					

**Impacts:** X = potentially important; blank = usually not important. **Extent:** L = local (up to tens of kilometers); P = present generation; R = regional (hundreds to thousands of kilometers); G = global; F = future generations.

**FIGURE 16.1.1** Overview of environmental burdens and major impact categories, with approximate indication of typical geographic extent and typical importance of impact.

## 16.2 Benchmarks and Reference Conditions

*Ari Rabl, Nevis Cook, Ronald R. Hewitt Cohen,  
and Tissa Illangasekare*

### Natural Environment

#### Air Basins

Unpolluted air is an idealization, but its composition has been defined as indicated in [Table 16.2.1](#). Unfortunately, measurements of truly unpolluted air were not and can never be made because measurement techniques and even the interest in measurements did not exist when air was unpolluted. Now even the most remote sites have mildly polluted air.

**TABLE 16.2.1 Gaseous Composition of Unpolluted Air (dry basis)**

	ppm (vol)	$\mu\text{g}/\text{m}^3$
Nitrogen	780,000	$8.95 \times 10^8$
Oxygen	209,400	$2.74 \times 10^8$
Water	—	—
Argon	9,300	$1.52 \times 10^7$
Carbon dioxide	315	$5.67 \times 10^5$
Neon	18	$1.49 \times 10^4$
Helium	5.2	$8.50 \times 10^2$
Methane	1.0–1.2	$6.56\text{--}7.87 \times 10^2$
Krypton	1.0	$3.43 \times 10^3$
Nitrous oxide	0.5	$9.00 \times 10^2$
Hydrogen	0.5	$4.13 \times 10^1$
Xenon	0.08	$4.29 \times 10^2$
Organic vapors	~0.02	—

Although measurements of the undisturbed atmosphere were not made, we can gain some insight into trends of air pollutant burden growth by examining emissions over the last century. [Figure 16.2.1](#) shows the growth of emissions of the classical air pollutant species since 1900. The latter two panels of the figure show that emissions from regulated sectors in the United States have abated in the past 20 years. Those regulations are described later. Note that [Table 16.2.1](#) uses two sets of units for gaseous pollutants, one volumetric, the other mass based. To convert from one to the other the ideal gas law is used with the result (at 1 atm and 25°C):

$$1 \text{ ppm} = \text{MW} * 40.9 \mu\text{g}/\text{m}^3$$

where MW is the molecular weight.

#### Surface Water Basins

Human activity has also dramatically altered the distribution, quantity, and quality of Earth's water, especially since the industrial revolution. Accurate measurement of many water impurities, particularly trace impurities, has only become possible in the latter part of the 20th century. Given the quantities and wide distribution of human-generated wastes delivered directly or indirectly (via atmospheric deposition or surface runoff and erosion) to water bodies, recent water quality surveys might not be representative of truly "natural" conditions. As an example, a "pristine," undeveloped alpine lake may show traces of plutonium that are residuals of 1950s through 1960s atmospheric testing of nuclear weapons. Lead from automobile emissions can be detected in the bottom sediments of the Atlantic Ocean, more than 1500 km from the nearest landmass. A tabulation of the averages and ranges of concentrations of many naturally occurring substances detected in minimally impacted waters can serve

**FIGURE 16.2.1** Trends in U.S. national emissions of air pollutants. (a)  $SO_2$  and  $NO_x$ , 1900–1980, all sources, residential  $SO_2$  and transportation  $NO_x$ . (b)  $SO_2$  and  $NO_x$ , 1900–1980, all sources and electric utility sources. (c)  $SO_2$  and  $NO_x$ , 1970–1990, all sources, transportation and electric utility sources. (d)  $SO_2$  and  $NO_x$ , and particulates, 1970–1990. (Data from EPA annual reports; Gschwandtner et al., 1985.)

as a benchmark, admittedly imperfect, against which to compare “polluted” waters, water quality criteria, and regulatory standards.

*Choice of Reference Conditions.* The authors propose as reference conditions, the concentrations of measured impurities in the oceans, “average” rainwaters, and “average” river waters. This choice of reference waters was based on two distinct criteria:

1. Either the volume of water was so large (such as the open oceans) that human activity has had little detectable effect on average water quality conditions, or
2. The waste input is small and the water body is rapidly and continuously renewed by unpolluted sources (such as a tributary to a major river).

The major and minor constituents of water and their quantities are easily presented in tables. The use of the word “major” indicates materials present or required in large quantities. Table 16.2.2 summarizes data on the constituents of selected natural waters. Note that the concentration data for major constituents

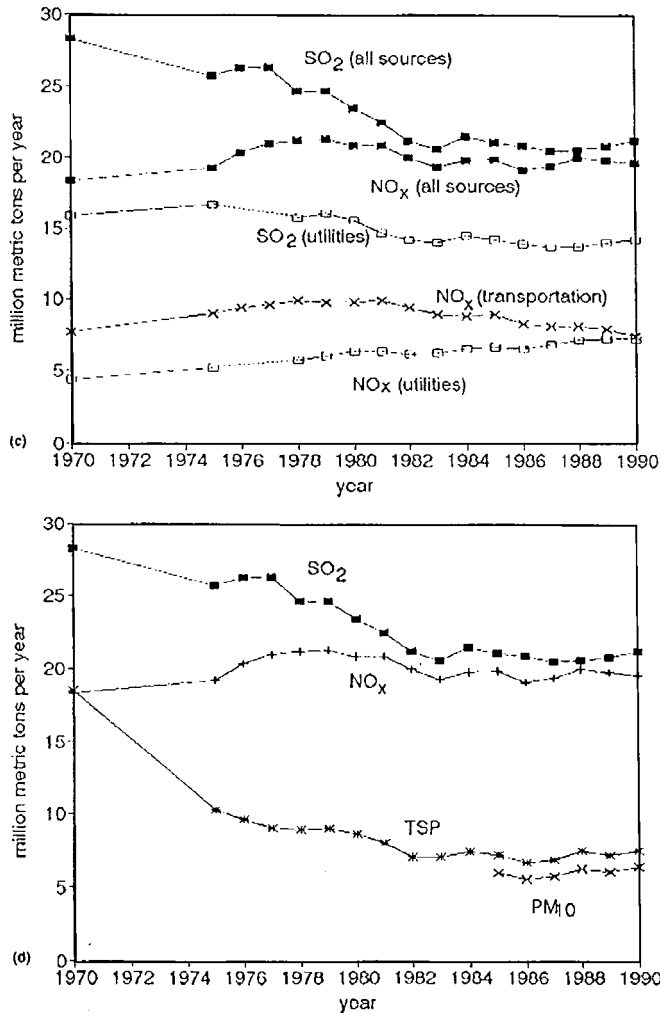

FIGURE 16.2.1 continued

(Table 16.2.2) is given in milligrams per liter and the concentration data for the minor constituents (Table 16.2.3) is given in micrograms per liter. Inclusion of boron and fluoride as major constituents is somewhat arbitrary and was based on their occurrence at greater than 1 mg/L in seawater. In these tables, individual entries are *average values* reported by U.S. regional or national surveys. *Ranges* are derived from the majority of the data from similar surveys, excluding data obtained from waters apparently contaminated by pollution. Some surveys presented results by stating that “very few” samples exceeded certain concentration values or simply reported measurements as “less than” due to analytical detection limits. These results are preceded by the symbol < in the tables. Although the data given are believed to be representative of water found in natural settings, it should be appreciated that, especially for industrially important trace constituents, the upper limits of the concentration ranges may include some small level of **anthropogenic** inputs.

There are additional categories of natural and contaminant components of water. There are complex, difficult to characterize, organic humic materials in natural water bodies that represent the end point of decay of formerly living organic matter. There are synthetic chemicals by the thousands, produced currently and in the past, by the chemical industry. Some of these compounds and polymers are completely new to the natural environment. Many are considered toxic to aquatic organisms and/or

**TABLE 16.2.2 Major Constituents and Characteristics of Natural Waters (constituent concentrations in mg/L, unless otherwise noted)**

Constituent	Oceans	Rivers	Rain
Cl <sup>-</sup>	19,000	5.8, 7.8	0.2–0.6
Na <sup>+</sup>	10,500	5.3, 6.3	0.2–0.6

humans. For lists of contaminants considered toxic and their effluent limitations, there are many documents available from the U.S. Environmental Protection Agency (USEPA) and other sources.

### Soils and Water Basin Definitions

The unconsolidated sediment that covers a comparatively thin mantle of the land surface in general is referred to as soil. Soils are complex mixtures of solid, liquid, and gases. The solid phase consists of a mineral inorganic fraction that is produced by weathering of rocks or transported material. The predominant inorganic elements are silicon, aluminum, and iron. The organic fraction consists of partially or fully decomposed products of flora and fauna. The liquid phase is the water that occupies the pore spaces between and within grains of the solid material. In its natural form this water, which is referred to as

soil water, contains dissolved substances introduced from the solids or transported from the ground surface. The pore spaces that are not occupied by water will be filled by water vapor, gases, and air. The complexity of soil systems derives from the fact that the mixture of the solid, liquid, and gases is very heterogeneous and that the composition of the individual phases and the mixture changes in space and with time.

The soils in their natural environment can be subjected to drastic changes not only as a result of the interaction among the solid, liquid, and gas phases but also by external factors that are controlled by pressure, temperature, and light. The physical and chemical characteristics of the changing solid phase have a significant influence on the thermal behavior, water retention and flow, adsorption and entrapment of chemicals and wastes, and transport of dissolved substances. All of the above processes are of importance in the study, understanding, and solution of problems in environmental sciences and engineering associated with soil contamination.

The physical characteristics of soils as a porous medium are affected by the shape, size and size distribution, and the arrangement of the solid phase or the soil grains. The *shapes* and *sizes* of the soil grains vary widely from small colloids to large sand and gravel. Particles that are less than the arbitrary size of 2  $\mu\text{m}$  are the clay fraction that is formed as a secondary product of weathering of rocks or derived from the transported deposits. These particles are platelike or disk shaped. The non-clay fraction formed from inert minerals and fragments of rock consists of silt, sand, and gravel. In a particle size classification used by agricultural scientists that was developed by the U.S. Department of Agriculture (USDA), non-clay particles that are in the size range 2 to 50  $\mu\text{m}$  are classified as silts, in the range 50 to 2000  $\mu\text{m}$  as sands, and above 2000  $\mu\text{m}$  as gravel. In this classification system the sands are further divided into subgroups of very fine, fine, medium, coarse, and very coarse sands. A second system, by the International Society of Soil Science (ISSS) that is also used by agricultural scientists, classifies silts to be in the range 2 to 20  $\mu\text{m}$ , fine sands 20 to 200  $\mu\text{m}$ , and coarse sands 200 to 2000  $\mu\text{m}$ . The American Society of Testing and Materials (ASTM) classifies colloids as particles that are less than 0.1  $\mu\text{m}$  in size.

The surface area of the solid particles contained in a known volume of the soil has a significant influence on the physical and chemical processes that occur on the surfaces of the soil grains. The ratio of the internal solid surface area to the total volume is referred to as the *specific surface*. This parameter is also sometimes expressed as the ratio of the surface area to the mass of the soil grains. This parameter of the soil is affected by the size and shape of the individual soil grains. Because of the platelike or disk-shaped nature of small clay particles, clays in general have very large specific surface compared with the non-clay particles (silts, sand, and gravel). For example, the three common clay minerals kaolinite, illite, and montmorillonite have specific surface of 45, 175, and 800  $\text{m}^2/\text{gm}$ , respectively (Corey, 1994). Because of these enormously large surface areas, the clay fraction in soils has a significant influence on the chemical reactive processes that are controlled by the surface area of the soil grains. The silt and sand fraction will not have a significant influence on the chemical processes, and also the smaller surface areas result in small water retention capacities as compared with clay.

The spaces between the grains that are referred to as intergranular pore spaces control the flow behavior and capacity to hold water by a soil. A physical parameter that is known as the *average porosity* or *porosity* characterizes the secondary pore space enclosed between the aggregates. The porosity of a soil sample is defined as the ratio of the volume of interconnected pores to the total volume of the sample. Soil porosity depends on many factors that include its structure, shape of soil grains, size distribution of the grains, the degree of mixing of the various-sized particles, and the way the soil grains are packed. Under conditions of normal packing the porosities of unconsolidated sand vary in the range 0.39 to 0.41 and soil with structure in the range 0.45 to 0.55. The organic matter in soil binds the inorganic fraction to form larger aggregates. The primary pore spaces within the soil aggregate play a significant role in retardation and attenuation of dissolved chemicals that are contained in the aqueous phase.

The subsurface soil–water environment that exists below the ground surface is divided into two zones, namely, the *unsaturated* or *vadose zone* and the *saturated zone*. In the unsaturated zone pore spaces contain both water and air. The capillary forces created by the surface tension in the water–air interfaces produce water pressures that are less than atmospheric (suction). The water flowing through

the unsaturated zone is subjected to capillary driving forces in addition to the gravitational forces. In the saturated zone, the water pores are fully saturated with water and the water pressures are greater than atmospheric. The water in the saturated zone is driven by gravitational forces. The surface that separates the unsaturated and saturated zones is referred to as the *water table*. By definition, the water pressure at the water table is atmospheric. The location of the water table below the ground surface at waste and spill sites becomes critical in determination of the fate and transport of pollutants in the subsurface soil–water environment as described later. Figure 16.2.2 shows the essentials of the situation schematically.

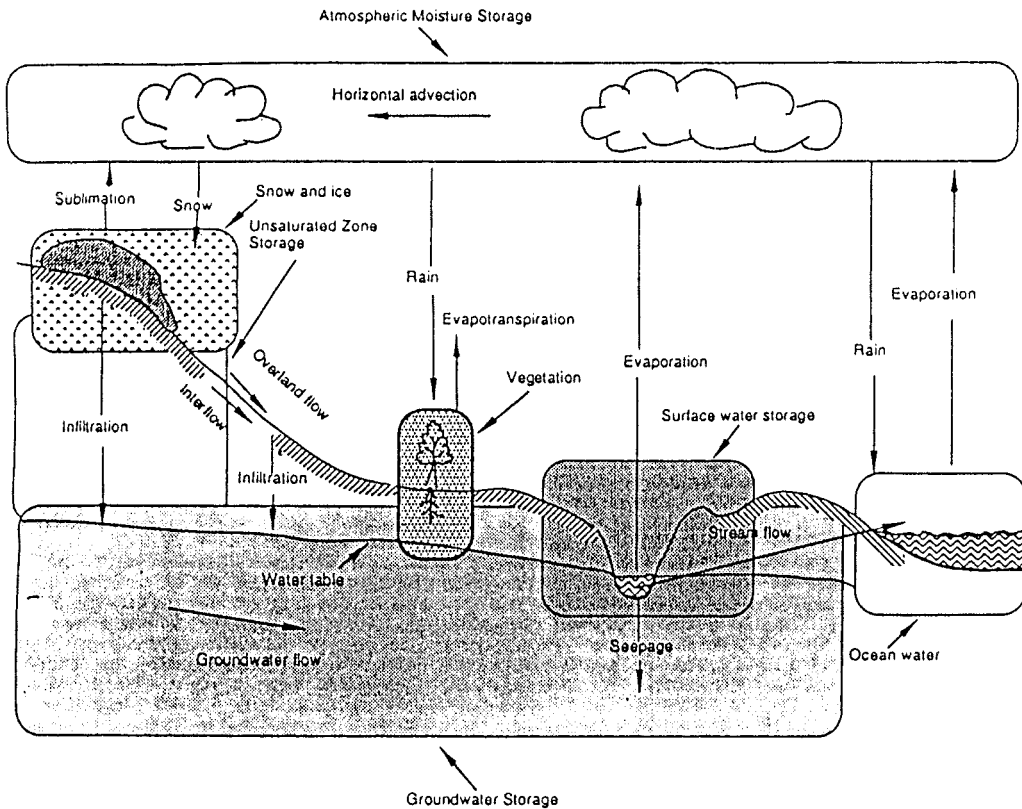

FIGURE 16.2.2 A column of Lagrangian boxes simulating atmospheric dynamics.

## Acceptable Levels of Pollutants

### Water

*Criteria vs. Standards.* The *objective* of water quality control programs, for example, is to protect current or potential *beneficial uses* of water. Criteria define the specific characteristics necessary to protect such uses. Criteria are not absolute, but are based on a combination of experience, current scientific knowledge, and the judgment of experts. Toxicological data for many of the water components often are limited. There may be results of tests for acute, or immediate, impact to organisms (including humans), but little information on impact on reproduction, long-term health or tolerance at low concentrations, organism adaptability, acclimatization, or interaction with other substances. General criteria are intended to protect sensitive species subjected to long-term exposure and may be overly conservative in specific situations. The aquatic life column of Table 16.2.4 presents typical, continuous, maximum concentration criteria for freshwaters intended to support a variety of aquatic life. Surface water quality criteria and their

**TABLE 16.2.4 Water Quality Criteria and Standards (inorganic contaminants in  $\mu\text{g/L}$ )**

Constituent	Beneficial Use or Protection Category

<sup>a</sup> Considered beneficial in drinking water at somewhat lower concentrations.

<sup>b</sup> Temperature and pH dependent, only unionized form ( $\text{NH}_3$ ) is toxic to aquatic life.

<sup>c</sup> Secondary standards based on use impacts (tastes, staining), not health related.

<sup>d</sup> Controversial, based on toxicity of  $\text{Ag}^+$ , rarely present in natural waters.

<sup>e</sup> Extremely low levels partly due to food chain bioaccumulation potential.

relationship to permitted discharges are further discussed later in this chapter. The irrigation criteria given in [Table 16.2.4](#) are intended to protect the yields of agricultural crops.

Due to resource limitations (time, money, data, or a shortage of knowledgeable experts), conservative criteria are often adopted as *standards*. Standards development should, however, include considerations of actual local needs and conditions, economics, technical feasibility, and the defined objectives of environmental policy. In contrast to criteria, standards are usually incorporated into laws and regulations and are often absolute. Either standards are violated or they are not.

Summarized as simple, USEPA (1979) definitions follow:

1. *Water Quality Criterion*: That concentration of a water quality measure that will meet a specific water use.
2. *Water Quality Standard*: The translation of a water quality criterion into a legally enforceable mass discharge of effluent limitation.

The drinking water column of [Table 16.2.4](#) presents a subset of the current U.S. National Standards for drinking water supplied to the public. The health-based standards are enforceable. It should be noted that the drinking water standards list in [Table 16.2.2](#) is not comprehensive. Maximum concentration levels (MCLs) for some inorganics, microbial contaminants, and the many regulated toxic organics have been omitted. Many drinking water MCLs are controversial because they rely on dose–response models which cannot be directly verified at the low levels of exposure that are typical.

## Air

[Tables 16.2.5 to 16.2.9](#) summarize the current U.S. ambient air quality standards for carbon monoxide, sulfur dioxide, nitrogen dioxide, ozone, and particulate matter. These criteria represent myriad effects depending on the receptor, species of pollutant, and duration and severity of impact. These criteria are

**TABLE 16.2.5 U.S. Ambient Air Quality Criteria for Carbon Monoxide**

CoHb in Blood, %	Associated Human Symptoms
80	Death
60	Loss of consciousness; death if exposure is continued
40	Collapse on exercise; confusion
30	Headache, fatigue; judgment disturbed
20	Cardiovascular damage; electrocardiographic abnormalities
5	Decline (linear with increasing CoHb level) in maximal oxygen uptake of healthy young men undergoing strenuous exercise; decrements in visual perception, manual dexterity, and performance of complex sensorimotor tasks
4	Decrements in vigilance (i.e., ability to detect small changes in one's environment that occur at unpredictable times); decreased exercise performance in both healthy persons and those with chronic obstructive pulmonary disease
3-6	Aggravation of cardiovascular disease (i.e., decreased exercise capacity in patients with angina pectoris, intermittent claudication, or peripheral arteriosclerosis)

CoHb = carboxy hemoglobin.

## 16.3 Sources of Pollution and Regulations

---

### Sources

*Jan F. Kreider, Nevis Cook, Tissa Illangasekare, and Ronald R. Hewitt Cohen*

#### Air

Air pollutants are found in the form of gases (e.g.,  $\text{SO}_2$ ) and particulate matter (e.g., fine dust). They are emitted into the atmosphere from natural sources (e.g., volcanoes) and *anthropogenic* sources (e.g., industrial activities). These pollutants are called “primary” because they are directly emitted from local sources. Primary pollutants may undergo chemical reactions that result in the subsequent formation of other species called “secondary” pollutants (e.g.,  $\text{O}_3$ ).

Air pollution is found at all spatial scales, ranging from a few meters (e.g., indoor pollution) to local, urban, regional, and global scales (Milford and Russell, 1993). *Indoor pollution* is of great concern because a large fraction of our time is spent indoors. Indoor sources of pollutants include combustion processes, aging materials (e.g., formaldehyde emitted from particleboard and plywood), and radon — a natural indoor pollutant which migrates through the soil and may penetrate and accumulate inside buildings. The *local scale* ranges from 100 m to a few kilometers. At this scale, pollution dynamics are dominated by atmospheric diffusion and the role of primary pollutants. The local scale is the one where we experience major exposure to toxic substances and flammable compounds during catastrophic and emergency releases.

The *urban scale* ranges from 10 to 100 km and is characterized by both primary and secondary pollutants. In fact, characteristic residence times are on the order of 1 or a few days, thus, allowing enough time for chemical transformation to play a role. Two types of urban smog are well known: the “London” smog and the “Los Angeles” smog. The former is characterized by stagnant, foggy meteorological conditions in winter which allow a buildup, over a few days, of  $\text{SO}_2$  and particulate matter. The latter, which has become the most common type of atmospheric pollution throughout the cities of the world, is a **photochemical** smog associated with clear, sunny days. Photochemical smog is a mixture of many gaseous compounds and particulate matter, among which the two most important constituents are ozone (a colorless secondary pollutant) and fine secondary particulate matter (such as sulfates, nitrates, and organic particles), which is responsible for most of the visual haze.

The *regional scale* ranges from hundreds to thousands of kilometers (the upper regional scale is also called *continental scale*). Characteristic residence times are on the order of 1 week. At this scale, pollution dynamics are dominated by chemical transformation and ground deposition phenomena. Acidic deposition, often referred to as *acid rain*, is a phenomenon in which acid substances, such as sulfuric and nitric acid, are brought to Earth by dry and wet deposition. Some lakes are very sensitive to acidic deposition because of their limited buffering capacity. *Global air pollution* is characterized by relatively unreactive compounds, such as  $\text{CO}_2$ , methane ( $\text{CH}_4$ ), and chlorofluorocarbons (CFCs). The long lifetime of these pollutants allows their global dispersion and accumulation.

Air pollution at any scale creates several adverse effects. Air pollution can just be a nuisance (e.g., odors) or be aesthetically offensive (e.g., visibility impairment). Some adverse effects, however, are of fundamental importance to the welfare of the population and public health. For example, many pollutants cause respiratory effects; some pollutants have mutagenic effects; others have shown carcinogenic effects; some pollutants also have synergistic effects (e.g., the damage of  $\text{SO}_2$  to the human respiratory system can be greatly enhanced by the presence of fine particles).

In the rest of this chapter, an overview is presented of analytical and numerical techniques for simulating air pollution phenomena. Air quality modeling is an essential tool for most air pollution studies today. Models can be divided into **deterministic** models, based on fundamental mathematical descriptions of atmospheric processes, and statistical models, based upon semiempirical relationships extracted from data and measurements. Deterministic models, in particular, have become a major tool

in providing objective assessment of air pollution scenarios and evaluating the effectiveness of different air pollution control measures. In fact, only deterministic models provide an unambiguous assessment of the fraction of responsibility of each pollution source in each receptor area, thus, allowing the definition and implementation of the most cost-effective cleanup strategy. Statistical models, instead, are useful in situations where deterministic models do not perform well, e.g., for real-time forecasting of air pollution episodes.

### Waterborne

Table 16.3.1 summarizes important sources of surface water pollution species by economic or technical sectors of the U.S. economy. An X indicates a key source and no entry indicates a second-order effect at most. Table 16.3.2 lists groundwater pollution sources by cause, extent and waste type.

### Soil and Groundwater

Various waste products and chemicals are generated from industrial, agricultural, commercial, and domestic activities. Unmonitored and uncontrolled long-term application on the land, accidental spillage, and improper storage and disposal result in these chemicals and wastes acting as potential sources of soil and groundwater contamination. La Grega et al. (1994) use an engineering classification system in which hazardous wastes are grouped under six categories, namely, inorganic aqueous waste, organic aqueous waste, organic liquids, oils, inorganic sludges/solids, and organic sludges/solids. In addition to these, pathogens and nuclear wastes act as sources of contamination. As most of these materials are fully or partially soluble in water, they ultimately will contaminate the water phase contained within the soil pores and the water passing through the soil both in the unsaturated and saturated zones of the subsurface. Figure 16.3.1 shows in schematic form how groundwater pollution occurs.

Inorganic aqueous wastes generated from manufacturing activities involving galvanizing, metal finishing, electroplating, etc. mostly contain acids, alkalis, or concentrated solutions of inorganic wastes such as heavy metals. Organic aqueous wastes are liquids that primarily contain mixtures of dilute concentrations of organic substances such as pesticides. Organic liquid wastes are complex mixtures or concentrated solutions of **organic compounds**. A common example of organic liquid wastes is halogenated solvents that are used in metal degreasing. Most of the oily wastes are derived from petroleum. Oils are used as fuels, lubricating oils in engines, and cutting oils in manufacturing. Inorganic sludges/solids wastes are produced from wastewater treatment, smelters, coking, and metal fabrication. Tars and sludges that are produced from manufacturing activities are some of the examples of wastes that are in the form of organic sludges.

Waste materials and chemicals are released to the soil and groundwater from various sources. The most common sources are leaking underground chemical storage tanks, septic tanks, municipal landfills, industrial landfills, surface impoundments, and abandoned hazardous waste sites. In addition, injection wells, regulated hazardous waste sites, land application, road salting, saltwater intrusion, and oil and gas brine pits contribute to soil and groundwater contamination.

The most frequent use of underground tanks is for storage of gasoline in service stations. Hazardous wastes and chemicals and oils are also stored in buried tanks at industrial sites, farms, and homes. The potential for leakage exists when these tanks corrode internally or externally. In addition, chemicals can leak from pipe joints or holes in the pipes that are connected to the tanks.

Older landfills that were not properly designed for containment of liquids or leachates were used to dispose of garbage, sludges from wastewater treatment plants, construction wastes and debris, incinerator ash, waste from foundries, and many other industrial and domestic hazardous and nonhazardous waste products. The chemicals in the landfill become a source of contamination when rain or surface water infiltrating through the landfill produces leachate. These leachates containing the dissolved constituents of the waste, eventually contaminate the underlying soil and groundwater. Modern well-designed landfills have synthetic liners and leachate-collection systems.

Surface impoundments in the form of open pits, lagoons, or ponds are designed to accept liquid wastes or mixed solids and liquids. The chemical wastes in these temporary storage sites are treated and

**TABLE 16.3.1 Sources of Water Pollution vs. Contaminant Emission Categories**

**FIGURE 16.3.1** Mechanisms of groundwater contamination (From Fetter, 1993).

discharged or allowed to evaporate or infiltrate into the ground. In addition, to store and dispose of wastewater and products from sewage treatment, surface impoundments are used in paper, mining, and oil and gas industries. They are also used in farms and large feed lots. In unlined impoundments, the liquids leak, and when undetected, can result in soil and groundwater contamination in large zones of the subsurface.

Because of the large number of septic tanks that are in operation in homes, small businesses, service stations, laundries, and industry, septic tanks have become a major source of soil and groundwater contamination. When these systems fail, the sludges or septage floods the drainage field and leachates that are generated act as a source of contamination. The discharges from septic tanks contain many organic and inorganic chemical products, suspended solids, fecal coliform, pathogenic bacteria and viruses, nitrates, and nitrites. Industrial septic systems used in commercial operations discharge hazardous waste chemicals that include synthetic organics (e.g., trichloroethylene, tetrachloroethylene, toluene, etc.) and heavy metals (e.g., lead, copper, and zinc).

Injection wells that are drilled into deep aquifers or aquifers that are not used for water supply are used to discharge liquid wastes into the subsurface. Large volumes of toxic, hazardous, and radioactive wastes that are generated in chemical, petroleum, metals, mining, and wood-treatment industries are disposed of using this method. The contamination of aquifers that are used for drinking water can occur when the injection wells are not designed properly and are placed in formations where the hydrogeologic conditions are not well known or understood.

Many types of agriculture-related activities use chemicals and produce wastes that contaminate soil and groundwater. Among these products are pesticides, fertilizer, and feed lot waste. Various types of pesticides are used in farming, golf courses, gardens, and parks to control insects and weeds. Many of the modern-day pesticides are biodegradable, but some of the stable ones are carried by rain and irrigation water through the soil to the groundwater. Fertilizers primarily contain nitrogen, potassium, and phosphorus. Because of comparatively high mobility in soil, nitrogen leachates are the primary contaminant of concern that is associated with application of fertilizers. Waste generated at large feed lots can introduce nitrogen, bacteria, and salts to the underlying aquifers. In addition to the above sources, the salts that get accumulated in soils from long-term application of irrigation water act as a source of soil and groundwater degradation.

In a treatment and disposal method known as land treatment, the wastewater and sludges that are generated from treatment plants and industrial operations are directly applied on the ground surface. Contamination of the soil and groundwater occurs when heavy metals, toxic chemicals, nitrogen, and pathogens leach through the unsaturated zone.

Another source of soil contamination is the radioactive wastes that are produced in the weapons and nuclear industries. These wastes are primarily associated with the elements uranium and plutonium. The ionizing radiation in the form of alpha and beta particles and gamma rays are damaging to human and animal life. As these contaminants follow a first-order exponential decay law, they remain hazardous for very long time periods on the order of hundreds to thousands of years. [Table 16.3.2](#) summarizes several of the key sources of groundwater pollution, their extent and the major associated pollutants.

## Pollutant Monitoring

*Jan F. Kreider and Tissa Illangasekare*

### Groundwater

Contaminants that are released to the aqueous phase from the soil or external sources move with the flowing groundwater creating a solute plume. Monitoring the groundwater flow velocity and the propagation of the solute plume is necessary to design schemes and strategies to protect the quality of groundwater that is used for drinking.

Monitoring wells are installed in aquifers to measure water pressure and to sample groundwater water quality. Wells in general consist of a standpipe with a screened interval. The screened interval allows for the aquifer water to flow into the well pipe. The water pressures are used to determine the head gradients, which in turn can be used to estimate the magnitude and direction of groundwater flow. Water samples that are collected at monitoring wells can be used to obtain information on the quality of groundwater.

Piezometric head is the sum of pressure and the elevation heads. The pressure head at any point in the aquifer intercepted by the screen is the height of the water surface in the well bore (or standpipe) above the point on the screen. The elevation head at a point is the elevation of the point above or below a datum. The gradient of the piezometric head determines the magnitude and direction of groundwater flow. By measuring the piezometric heads at many monitoring wells it is possible to draw the contour lines of equal piezometric head or potential. A flow net is obtained by constructing a set of flow lines that are orthogonal to the equipotential lines. The groundwater flow direction at a point is determined by drawing a tangent to the flow line passing through the point. By constructing the flow net so that the intersection of equipotential lines and the flow lines form curvilinear squares, it is possible to estimate the groundwater flow velocities and discharge in an aquifer. The monitoring well data can also be used to calibrate a groundwater model that then can be used to estimate and monitor groundwater flow.

Groundwater samples collected from monitoring wells can be analyzed in the laboratory to determine the chemical contents. Probes can be inserted into the monitoring wells for the *in situ* measurement of conductivity and pH.

*Process Emissions Monitoring.* Methods and instrumentation for the monitoring of industrial waste discharge streams are discussed in detail in the USEPA *Handbook for Sampling and Sample Preservation of Water and Wastewater*. ASTM publishes a frequently updated *Annual Book of ASTM Standards* that extensively details recommended sampling techniques.

The topic of sampling is complex and includes sampling timing and frequency; sample preservation (until analyses can be done); sample preprocessing (i.e., filtering to separate particulate and dissolved components); questions of whether waste streams are continuously monitored for particular environmental variables or whether discrete samples are taken; whether a single “grab” sample is taken or a series of samples in time or space are retrieved and composited into a single “representative” sample; whether there is a single, worker-sampled, grab sample of an automated, continuous sampling apparatus; whether there is retention of volatile compounds for later analysis. Additionally, there are issues of

laboratory analytical techniques, quality control, and quality assurance from the moment of sampling through the reporting of the data, acceptable detection limits, sample contamination, materials used to sample particular chemicals. The only way to account for all these variables is to know thoroughly the data-reporting requirements of the industrial discharge permits or agreements. Also, the objectives of the sampling and the compounds of concern will dictate the entire structure of the sampling regime. The authors will discuss, briefly, some of the above topics.

The ideal characteristics of a process waste discharge stream for monitoring are steady, uniform flow that is chemically homogeneous throughout the cross section. Under such conditions, several grab samples over the day may yield representative results. In many industries, the waste streams vary due to process switching, change of shifts of workers, and cleaning and preparation of process equipment and machinery. Several specified times a day a local beer brewery flushes process wastes from the floor using high-pressure hoses. Occasional grab sampling might miss completely this pulse of waste load to the treatment system. There are continuous sampling devices that take a grab sample at specified time periods, then rotate to another sample bottle in preparation for the next sample. There are more-sophisticated samplers that draw in a sample at time intervals proportional to stream discharge. Often, the type and frequency of discharge sampling is specified in the discharge permit. For best results, the sampling planner or coordinator should know the plant operation cycles in order to be able to characterize the time variation of discharges.

The material of which a sampling device and storage vessel is constructed must be matched to the materials sampled. Some organics require the use of tetrafluoroethylene (Teflon) tubing and glass storage vials that have been washed with an organic-free cleanser. Using the wrong tubing may result in the leaching of plasticizers into the sample. It is recommended that metal sampling devices *not* be used for collection of metal-laden discharge samples that require later analysis for metal ions. Samplers must be washed between samplings to avoid sample cross contamination.

*Environmental Quality Monitoring.* Most of the mechanics and issues of sampling discussed just above for monitoring discharges hold true for environmental sampling, i.e., after the discharge has entered a stream or lake. Detailed sampling plans must be prepared. Existing data is gathered (from company files; land use maps; USEPA; U.S. Geological Survey gauging and water quality station results; state departments of environment, resources, and health; other federal and local agencies). It helps to have site characteristics prior to the inception of the waste discharge.

The data collection for environmental monitoring often is governed by legal considerations concerning the validity and admissibility of the data. To this end, a quality assurance/quality control (QA/QC) plan must be prepared according to USEPA or state guidelines. These plans will specify the frequency of taking duplicate samples (taken at approximately the same time and place), split samples (one sample is split into two, separate containers), spiked samples (an additional injection of chemicals anticipated to be in the environmental sample are added to a duplicate sample, and the recovery of that known amount of spike is reported). A good QA/QC operation will ensure that the best effort is being made to

1. Obtain representative samples,
2. Use appropriate sampling methods,
3. Use appropriate analytical methods,
4. Ensure adequate records of chain of custody of samples, and
5. Develop a sound and acceptable database.

The USEPA can be contacted to send *Interim Guidelines and Specifications for Preparing Quality Assurance Project Plans* (or QAPPS — pronounced “kwaps”).

Other documents that may be required include

1. Sampling plans;
2. Site background information;
3. Planned sampling locations;

4. Planned sampling methodology and sample preservation (some chemicals decay on exposure to light, microbes may induce decomposition of organic compounds at ambient temperatures, chemically reduced compounds may oxidize on exposure to a head space of air, volatile compounds may escape from an insufficiently sealed vial, solid materials may dissolve, or dissolved materials may precipitate);
5. Health and safety plans;
6. Plans for sample-handling procedures and chain of custody of samples;
7. Request forms for sample analyses;
8. Frequency and format of data reports.

### **Air Quality Monitoring**

Air quality monitoring has many of the same goals and general techniques as water quality monitoring. A stationary monitoring network should yield the following information:

1. Background concentration
2. Highest concentration levels
3. Representative levels in populated areas
4. Impact of local sources
5. Impact of remote sources
6. Relative impact of natural and anthropogenic sources

Spatial scales range from micro- (up to 100 m) to regional scales (tens to hundreds of kilometers). Site selection is a key part of network design because microclimates can affect readings and cause them to be nonrepresentative of the region.

Mobile monitoring is useful when sites not monitored with the fixed network need assessment. The key drawback of such systems is the sparsity of equipment suitable for reliable and durable mobile monitoring. Remote sensing offers a second alternative to stationary networks.

Quality assurance is a continuous concern of monitoring systems. Good instrumentation installation and maintenance practice with careful record keeping is essential.

Space precludes presentation of further details on air quality monitoring, but Boubel et al. (1994) has a thorough overview.

## 16.4 Regulations and Emission Standards

---

### Water

*Nevis Cook and Ronald R. Hewitt Cohen*

The Clean Water Act (CWA) of 1972 and its amendments establish the framework of current U.S. water pollution control. This act is sometimes referred to as the Federal Water Pollution Control Act Amendments after the original 1965 act which the CWA amended. The objective of the CWA is to “restore and maintain the chemical, physical, and biological integrity of the nation’s waters.” The CWA regulates both nonpoint (runoff from farmlands, roads, and city streets) and point sources (discharges from pipes conveying pollutants to surface waters) of water pollution. The discussions in this chapter are limited to regulation of point sources of pollution to *surface* waters. Discharges to groundwaters are regulated under the Safe Drinking Water Act (SDWA) underground injection control (UIC) program and are beyond the scope of this chapter. The discussion is still quite broad, since all domestic and industrial wastewater discharges are considered point sources under the CWA.

*Discharge Permits.* The CWA prohibits point source discharges to surface waters unless a *discharge permit* is obtained. Permits typically are issued at the state level and are known as state pollution discharge elimination standards (SPDES) permits. If the state has not taken over this responsibility, national (NPDES) permits are issued by the USEPA. The permit for each point source prescribes allowable discharges in terms of amount and concentration of flows and pollutants. In some cases, an industrial facility may avoid obtaining its own permit by discharging into the local public sewer system. Control of these *indirect discharges* is accomplished by requiring publicly owned treatment works (POTWs) receiving such discharges to enter into formal *pretreatment agreements* with industrial users of the sewer. Such pretreatment agreements are intended to prevent industrial discharges to POTWs which would represent a hazard to the sewer system or its workers, interfere with treatment operations or sewage sludge disposal, or pass through the treatment process causing a violation of the POTW discharge permit.

*Permitted Discharges.* Prior to the CWA of 1972, point source water pollution control laws were established at the state level and permitted discharge of pollutants on a discharger-by-discharger and water-body-by-water-body basis. This approach worked poorly in most states, demonstrating the need for enforceable *federal minimum effluent standards*. For this reason, the CWA and subsequent amendments have established *technology-based* national minimum pretreatment and discharge standards. Technology-based standards reflect the current state of the art with respect to controlling specific pollutant discharges from specific pollution sources. Since technology-based standards represent the capabilities of typical “well-operated” facilities and are not issued on the basis of in-stream water quality, it is not surprising that in some cases compliance with national minimum standards does not adequately protect all potential uses of a water body. In such cases the uses of the receiving water body are said to be *water quality limited*, and *local discharge limits*, more stringent than national limits, may be imposed. In addition, pretreatment agreements reflect the capabilities of local treatment works with respect to pass through, destruction, or partitioning of nondegradable toxic metal pollutants into POTW sludges. Following the development of local water quality-based limits, these are compared with national minimum technology-based standards and the more restrictive criteria are imposed as discharge permit or pretreatment limitations. Further considerations with respect to setting permit values are presented below.

Industrial dischargers may obtain an industrial NPDES permit and directly discharge wastewater to a receiving water body. Alternatively, where municipal sewer service is available, industries may choose to negotiate a pretreatment agreement with the local sewer authority permitting discharge of industrial wastewater to the sewer system. Most industrial facilities employing either discharge option (direct or indirect) are subject to national technology-based minimum effluent standards. In addition, more-stringent standards may be imposed at the state or local level.

State permits containing discharge constraints more stringent than the national minimum standards are commonly derived from local water quality considerations. Ideally, local water quality-based

standards are developed from science-based use protection criteria, wastewater flow data, and actual receiving water characteristics (such as low-flow conditions for streams). Rational direct discharge permits to streams or rivers can be developed by application of the following procedure: convert use-based, in-stream quality criteria to standards according to local policy; obtain data on upstream water quality and low-flow conditions (conditions at which the waste assimilative capacity of a stream is at a minimum) and determine potential for dilution of the wastewater flow by the receiving water body; compute the allowable water quality-based industrial discharge on a pollutant-by-pollutant basis and compare with national minimum standards; finally, impose permit restrictions according to the most stringent of the two types of standards developed.

Development of water quality-based permits for direct discharges to lakes, estuaries, bays, or oceans follows a procedure similar to that outlined above. However, estimates of mixing patterns and the dilution potential of these water bodies are likely to be more difficult because of the complex flow patterns involved. Water quality-based pretreatment standards for discharges to sewers also follow the same general procedure. However, in this case, the application of use criteria, policy, and potential for in-stream dilution lead to a pollutant-by-pollutant permit for the *local* POTW. Based on this permit and the removal capabilities of the treatment facility, maximum allowable (usually daily) loading of pollutants arriving at the plant is determined on a pollutant-by-pollutant basis. Allowable loads are then allocated to the various municipal and industrial users of the sewer. Setting water quality-based pretreatment standards is obviously complicated by the presence of multiple sewer uses and users. Thus, POTWs receiving significant industrial discharges are required to set up formal programs to negotiate industrial pretreatment agreements and monitor compliance.

## Air

*Jan F. Kreider*

The U.S. Clean Air Act Amendments of 1977 set forth two air quality standard types:

- Primary (protect health)
- Secondary (protect health and prevent other adverse impacts)

Table 16.4.1 summarizes the present primary and secondary standards in the U.S. The amendments also specified for certain geographical areas further standards to prevent significant deterioration (PSD areas). These are standards that are to be considered increments over baseline air quality but are more stringent than secondary or primary standards in most cases. Table 16.4.2 lists these PSD standards.

**TABLE 16.4.1 U.S. Federal Primary and Secondary Ambient Air Quality Standards**

Pollutant	Type of Standard	Averaging Time	Frequency Parameter	Concentration	
				µg/m <sup>3</sup>	ppm
Sulfur oxides (as sulfur dioxide)	Primary	24 hr	Annual maximum	365	0.14
		1 year	Arithmetic mean	80	0.03

## 16.5 Mitigation of Water and Air Pollution

---

This section discusses the methods for abating or mitigating air and water pollution burdens on the environment. Because mechanical engineers are most concerned with air pollution control systems and civil engineers deal with water treatment systems, this section emphasizes the air pollution mitigation side.

### Overview

*Jan F. Kreider*

There are several methods for controlling air- or waterborne pollution:

- Process change
- Fuel change
- Pollution removal and disposal
- Pollution prevention

*Process change* includes everything from modifications that reduce emissions to substitution of a less polluting one for a more polluting one. The latter could be classified as pollution prevention, described shortly. In many cases, for example, in the steel industry, it has proved most economical to replace completely old plants with totally new ones. Likewise, complete substitution has been widely adopted in the pulp and paper industry.

*Fuel change* as a control strategy is based on the fact that airborne pollutants often are related to the combustion aspects of a process. For example, coal-fired power plants emit SO<sub>2</sub> because coal contains sulfur. Substitution of natural gas for coal eliminates any sulfur in the fuel and, therefore, any oxides of sulfur in the stack gases.

Fuel changes must consider fuel supply, capital cost, and competition for clean fuels among many industries before an engineering design decision can be made. Life cycle methods that consider all parts of the life of a plant are necessary. For example, a nuclear power plant may produce very low emission electricity but after decommissioning may cause long-term waste disposal problems.

*Pollution removal* is necessary when process or fuel changes cannot provide adequate emission control. A physical, chemical, or electrical feature of the pollutant to be removed must differ from those types of characteristics of the carrying gas or liquid stream. An example is a baghouse or electrostatic precipitator for particulate emissions. Not only collection of pollutants but also disposal of the collected pollutant must be considered by the design engineer. A whole systems viewpoint is necessary for a successful pollution removal design.

Pollutant disposal is governed by different criteria depending on whether it is hazardous or not. Hazardous waste disposal is covered by the Resource Conservation and Recovery Act of 1976, which established the Office of Solid Waste with the USEPA. On the other hand, nonhazardous waste disposal is governed by the states. [Table 16.5.1](#) categorizes the ultimate disposal methods for classes of hazardous wastes. Many of the methods apply for nonhazardous wastes as well.

*Pollution prevention* is the ultimate solution to abatement. This can be accomplished at the source by various technical means, depending on process specifics. This approach is currently the most commonly used term by the USEPA. The Pollution Prevention Act of 1990 stated these policies:

- Prevent or reduce pollution at the source whenever possible;
- Recycle to the environment pollution that cannot be prevented in a safe manner whenever possible;
- Pollution that can neither be prevented nor recycled should be treated in as environmentally safe a manner as possible;
- Disposal or other release into the environment should be used as only a last resort.

**TABLE 16.5.1 Ultimate Waste Disposal Methods**

Process	Purpose	Wastes	Problems (Remarks)
Cementation and vitrification	Fixation	Sludges	Expensive
	Immobilization	Liquids	
Centrifugation	Dewatering	Sludges	—
	Consolidation	Liquids	
Filtration	Dewatering	Sludges	Expensive
	Volume reduction	Liquids	
Thickening (various methods)	Dewatering	Sludges	—
	Volume reduction	Liquids	
Chemical addition (polyelectrolytes)	Precipitation	Sludges	Can be used in conjunction with other processes
	Fixation	Liquids	
	Coagulation		
Submerged combustion	Dewatering	Liquids	Acceptable for aqueous organics
<b>Major Ultimate Disposal Methods</b>			
Deep well injection	Partial removal from biosphere	Oil field brines; low toxicity, low-persistence wastes; refinery wastes	Monitoring difficulty; need for special geological formations; groundwater contamination
Incineration	Volume reduction Toxicity destruction	Most organics	If poor process control, unwanted emissions produced Can produce NO <sub>x</sub> , SO <sub>x</sub> , halo acids
Recovery	Reuse	Metals Solvents	Sometimes energy prohibitive
Landfill	Storage	Inert to radioactive	Volatilization
<b>Major Waste Disposal Methods</b>			
Land application	Isolation		Leaching to groundwater
Land burial	Dispersal		Access to biota
Ocean disposal	Dispersal	Acids, bases	Contact with ocean ecosystem; containers unstable
	Dilution	Explosives	
	Neutralization	Chemical war agents	
	Isolation(?)	Radioactive wastes	
<b>Minor Disposal Methods</b>			
Biological degradation	Reduction of concentration Oxidation	Biodegradable organics	Most hazardous wastes do not now qualify
Chemical degradation (chlorination)	Conversion	Some persistent pesticides	—
	Oxidation		
Electrolytic processes	Oxidation	Organics	—
Long-term sealed storage	Isolation	Radioactive	How good are containers?
	Storage		
Salt deposit disposal	Isolation	Radioactive	Are salt deposits stable in terms of waste lifetimes?
	Storage		

## Air Pollution Control

*Jan F. Kreider*

The most common method of meeting emission standards in industries that must control air pollution is by *pollution removal*. This section describes the most widely used approaches. [Table 16.5.2](#) lists the important characteristics of control systems for airborne pollutants.

Dry particulate matter is removed by

Reactivity		

- Filters — baghouse, fixed beds, or mats
- Electrostatic precipitators — plate-type, tube-type; see [Figure 16.5.1](#)
- Inertial collectors — cyclones and baffles; see [Figure 16.5.2](#)
- Scrubbers — wet or dry

[Table 16.5.3](#) lists the key characteristics of these technologies, where they are best applied, and annual operating, capital, and maintenance costs in \$1994. Of course, a design is needed upon which a quotation for final cost studies can be based.

Liquid droplets and mists are controllable by

- Filters — more loosely knit than for dry filters
- Electrostatic precipitators — wetted wall type
- Inertial collectors — cyclones and baffles
- Venturi scrubbers

**FIGURE 16.5.1** Wet-wall electrostatic precipitator with tubular collection electrodes. (From Oglesby, S., Jr., and Nichols, G. B., in *Air Pollution*, 3rd ed., Vol. IV, A. C. Stern, Ed., p.238, Academic Press, New York, 1977. With permission.)

	10.0–50.0	Good	Large	500	10	42.00

<sup>a</sup> Includes water and power cost, maintenance cost, operating cost, capital, and insurance costs (in \$ 1994).

Finally, gaseous pollutants can be controlled using

- Absorption materials — wet scrubber, packed tower, or bubble tower; see [Figure 16.5.3](#), for example;
- Adsorption materials — porous media such as activated charcoal, silica gel, and alumina;
- Condensers — widely used in the chemical process industries;
- Chemical conversion to contaminants — oxidize hydrocarbons to CO<sub>2</sub> and H<sub>2</sub>O, for example.

[Table 16.5.4](#) compares gaseous pollutant removal systems.

Cataloging of industry-specific designs is beyond the scope of this handbook because of space limitations. The reader is referred to Boubel et al. (1994) for details. One must make an inventory of emissions and then identify the most appropriate control methods based on operating and capital costs considerations. For example, [Table 16.5.5](#) shows common emissions and control methods for the petrochemical industry. The energy, power generation, incineration, ferrous and nonferrous metallurgical, agricultural, and mineral/mining industries produce considerable emissions that must be controlled in accordance with federal regulations.

**FIGURE 16.5.3** Cutaway drawing of a flue gas desulfurization spray tower absorber. (Courtesy of CE Power Systems, Combustion Engineering, Inc.)

**TABLE 16.5.4** Comparison of Gaseous Pollutant Removal Systems

Type of Equipment	Pressure Drop (cm H <sub>2</sub> O)	Installed Cost (U.S. \$/m <sup>3</sup> )	Annual Operating Cost (U.S. \$/m <sup>3</sup> )
Scrubber	10	9.80	14.00
Absorber	10	10.40	28.00
Condenser	2.5	28.00	7.00
Direct flame afterburner	1.2	8.20	8.40 + gas
Catalytic afterburner	2.5	11.60	28.00 + gas

## Water Pollution Control

*Nevis Cook and Ronald R. Hewitt Cohen*

Control of waterborne pollutants is at present undertaken by nine distinct techniques:

- Biological oxidation
- Chemical oxidation
- Chemical reduction
- Conventional treatment
- Precipitation
- Air stripping
- Activated carbon

**TABLE 16.5.5 Air Pollution Emissions and Controls: Petrochemical Processes**

Petrochemical Process	Air Pollutant Emissions	Control Methods in Use
Ethylene oxide (most emissions from purge vents)	Ethane, ethylene, ethylene oxide	Catalytic afterburner
Formaldehyde (most emissions from exit gas stream of scrubber)	Formaldehyde, methanol, carbon monoxide, dimethyl ether	Wet scrubber for formaldehyde and methanol only; afterburner for organic vent gases
Phthalic anhydride (most emissions from off-gas from switch condensers)	Organic acids and anhydrides, sulfur dioxide, carbon monoxide, particulate matter	Venturi scrubber followed by cyclone separator and packed countercurrent scrubber
Acrylonitrile (most emissions from exit gas stream from product absorber)	Carbon monoxide, propylene, propane, hydrogen cyanide, acrylonitrile, acetonitrile NO <sub>x</sub> from by-product incinerator	Thermal incinerators (gas-fired afterburners or catalytic afterburners)
Carbon black (most emissions from exit gas stream from baghouse, some fugitive particulate)	Hydrogen, carbon monoxide, hydrogen sulfide, sulfur dioxide, methane, acetylene	Waste heat boiler or flare (no control for SO <sub>2</sub> )
Ethylene dichloride (most emissions from exit gas stream of solvent scrubber)	Particulate matter (carbon black) Carbon monoxide, methane, ethylene, ethane, ethylene dichloride, aromatic solvent	Baghouse None at present, but could use a waste heat boiler or afterburner, followed by a caustic scrubber for hydrochloric acid generated by combustion

- Ion exchange
- Reverse osmosis

Table 16.5.6 summarizes these approaches and their applications by contaminant type. The letter A in the table indicates the best available technology, whereas a B indicates an alternative that may apply to a subclass of industries. The reader is referred to the notes to the table for further details.

TABLE 16.5.6 General Effectiveness of Treatment Technology vs. Contaminant Type

Constituent	Biological Oxidation	Chemical Oxidation	Chemical Reduction	Conventional Treatment	Precipitation	Air Stripping	Activated Carbon	Ion-Exchange	Reverse Osmosis
BOD	A	—	—	—	—	—	—	—	—
COD	B	B	—	—	—	—	B	—	—
MOs <sup>a</sup>	—	A	—	A	A	—	—	—	I

SOC <sup>e</sup>	B	B	—	—	—	—	—	—	A
VOC <sup>f</sup>	B	B	—	—	—	A	B	—	B

A = treatment technology commonly applied to reduce contaminant to acceptable levels; perhaps best conventional technology. B = treatment technology that has been used to remove a particular contaminant, but might not be fully effective under all conditions. I = substance could interfere with efficient removal of other contaminants. P = pretreatment required if technology is to be used.

<sup>a</sup> MO = microbiological contaminants including pathogenic bacteria, protozoa, and viruses.

<sup>b</sup> Turb. includes fine colloidal matter and suspended solids, for true suspended solids use sedimentation.

<sup>c</sup> Total dissolved solids (TDS) includes removal of the highly soluble ions: Na<sup>+</sup>, K<sup>+</sup>, Cl<sup>-</sup>, SO<sub>4</sub><sup>2-</sup>.

<sup>d</sup> Includes the valence +2 transition metals: Cu<sup>++</sup>, Ni<sup>++</sup>, Pb<sup>++</sup>, Zn<sup>++</sup>.

<sup>e</sup> SOC = synthetic organic compounds, including pesticides.

<sup>f</sup> VOC = volatile organic compounds, including solvents.

## 16.6 Environmental Modeling

### Air Pollution Dispersion Modeling

*Paolo Zannetti*

To understand air pollution, it is mandatory, at any scale, to simulate correctly the dispersion characteristics of the emissions. Therefore, the role of meteorology is essential. Pollutants are typically transported by two types of flows: an “ordered” flow, which is characterized by average wind speed and direction, and a semirandom, turbulent flow, which is characterized by wind fluctuations. All dispersion models aim at simulating these two components. As further discussed below, dispersion modeling techniques can be categorized into four general classes: (1) Gaussian models; (2) Eulerian grid models; (3) Lagrangian box models; and (4) Lagrangian particle models.

#### Gaussian Models

All Gaussian models assume that the concentration of pollutants maintains a Gaussian distribution in space. The Gaussian distribution, as illustrated in Figure 16.6.1, is a symmetrical bell-shaped distribution which is described at any given point  $x$  by two parameters: the location of the peak (in this case, the centerline of the plume indicated by the segmented line) and the standard deviation (in this case, the spread of the plume mass about its center). Therefore, the dilution rate of the plume is fully characterized by the two standard deviations,  $\sigma_y$  and  $\sigma_z$ , expressed as a function of the downwind distance,  $x$ .

**FIGURE 16.6.1** The Gaussian plume in a wind-oriented coordinate system (i.e., the wind is blowing toward the  $x$  axis). The plume is released from a source located at  $(0, 0, h_s)$  and possesses an initial buoyancy. Therefore, the plume behaves as if it were originated from  $(0, 0, H)$ , where  $H$  is the effective emission height and  $\delta h = H - h_s$  is the plume rise. The plume is advected by the average wind speed  $\bar{u}$  and expands in the horizontal and the vertical direction while maintaining a Gaussian distribution along both.

In mathematical notation, the Gaussian plume formula in Figure 16.6.1 can be written as

$$c = \frac{Q}{2\pi\sigma_y\sigma_z\bar{u}} \exp\left[-\frac{1}{2}\left(\frac{y}{\sigma_y}\right)^2\right] \exp\left[-\frac{1}{2}\left(\frac{H-z}{\sigma_z}\right)^2\right] \quad (16.6.1)$$

where  $c$  is the concentration computed at the receptor  $(x, y, z)$ ,  $Q$  is the emission rate,  $\bar{u}$  is the average horizontal wind speed,  $H$  is the effective emission height, and  $\sigma_y$  and  $\sigma_z$  are functions of the downwind

distance,  $x$ , with parameters that vary with the meteorological conditions (in fact, the stronger the turbulence intensity of the atmosphere, the larger the growth rate of  $\sigma_y$  and  $\sigma_z$  with  $x$ ).

As can easily be seen, Equation (16.6.1) refers to a stationary state (i.e.,  $c$  is not a function of time), uses meteorological parameters that must be considered homogeneous and stationary in the modeled area (i.e., between the source and the receptors at which concentrations are computed), and cannot work in calm conditions where the wind speed approaches zero (in general, the wind speed cannot be less than 1 m/sec when Equation (16.6.1) is applied). In spite of these limitations, the simplicity of the Gaussian approach, its relative ease of use, and, especially, the elevation of this methodology to the quantitative decision-controlling level in the United States (USEPA, 1978) have stimulated research aimed at removing some of the limitations of the Gaussian theory in modeling the real-world situations.

Equation (16.6.1) has been modified and expanded to incorporate, among others, the following factors: ground reflection, multiple reflections, hourly simulations, deposition and decay, chemical transformation, fumigation, complex terrain, gravitational settling, calm conditions, nonstationary and nonhomogeneous conditions, and long-term simulations. We summarize below some of these improvements.

Reflection terms can be added to Equation (16.6.1) to account for partial or total reflection of concentration at the ground. Similarly, reflection can be added at the top of the **planetary boundary layer, PBL** (typically, about 500 to 1000 m above the ground). If both reflections are implemented, the plume is trapped inside the PBL. Equation (16.6.1) is generally applied for periods of 1 hr. This allows the incorporation of time-varying emission and meteorological parameters. Chemistry and decay can be incorporated by introducing exponential decay terms (for example, it can be assumed that an emission of primary gaseous  $\text{SO}_2$  is transformed into particulate matter  $\text{SO}_4^{2-}$  at a rate of 1% per hour). Gravitational settling will affect a plume of primary particulate matter. In this case, the plume centerline can be tilted to account for the settling velocity of the particles, which is a function of both particle size and density.

In addition to the Gaussian plume model, Gaussian segment and puff models can be used (Zannetti, 1986a). These models break up the plume into independent elements (plume segments or puffs) whose initial features and time dynamics are a function of time-varying emission and meteorological conditions encountered by the plume elements. These techniques allow us to account properly for nonhomogeneous, nonstationary conditions. Gaussian puff models, in particular, have the additional advantage of being able to simulate calm or low-wind conditions.

Complex terrain conditions affect the plume dynamics, both the motion of the centerline trajectory and the growth of  $\sigma_y$  and  $\sigma_z$ . Finally, the Gaussian plume model equation can be rewritten in a way to simulate long-term concentration averages (e.g., annual averages) by incorporating the joint frequency of occurrence of a predetermined set of emission and meteorological conditions.

### Other Models

Eulerian grid models (Lamb [from Longhetto], 1980) simulate pollutant diffusion by superimposing a grid over the computational domain and numerically solving a mass-balance equation (typically, a partial differential equation, PDE, or a set of PDEs) in each grid cell at each time step. This is also called numerical integration. In general, the smaller the grid and time intervals, the more accurate the numerical solution.

Difficulties may be encountered in simulating atmospheric diffusion with the K-theory. In particular, the application of the K-theory to simulate vertical dispersion during daytime, unstable meteorological conditions is highly questionable. To improve the simulation ability of Eulerian grid models, equations of high-order moments of concentration, wind, and temperature fluctuations can be solved simultaneously. This approach is called high-order closure and requires the definition of more-complex, nonlinear relationships between the turbulent fluxes and the concentration fields.

Lagrangian box models are mostly used to perform fast simulations of photochemical smog. These models define a set of “boxes” (e.g., a column of boxes as illustrated in [Figure 16.6.2](#)) which are advected horizontally according to the local wind speed and direction. Each box encounters emissions along its trajectory. These emissions inject new pollutants inside the box. A full set of chemical reactions inside

**FIGURE 16.6.2 Lagrangian box modeling.**

each box allows the simulation of the photochemical smog and the formation of secondary pollutants, such as ozone.

Lagrangian particle models provide a very interesting alternative method for simulating atmospheric diffusion. Particle motion can be produced by both deterministic velocities and semirandom pseudoveLOCITIES generated using Monte Carlo techniques. In the latter case, the trajectory of a single particle represents a realization from an infinite set of possible solutions, and, if enough particles are used, important characteristics can be inferred from the computation of particle **ensemble average** properties.

When using Lagrangian particle models to simulate air pollution, pollutant emissions (both gases and particulate matter) are represented by the injection of fictitious particles into the computational domain. Each particle represents a specified amount of pollution and is moved at each time step by a pseudoveLOCITY that is time and space dependent. Zannetti (1990) discusses alternative modeling approaches in more detail than is possible here.

### Atmospheric Chemistry

Atmospheric chemistry deals essentially with four major issues (Seigneur, 1987): (1) photochemical smog in sunny, urban areas; (2) **aerosol** chemistry; (3) acidic deposition; and (4) air toxics. Chemical reactions can be simulated in two ways: (1) with simple first-order terms (e.g., a decay term) and (2) with a full chemical reaction scheme.

First-order terms for simulating atmospheric chemistry can be easily incorporated into any of the models previously discussed. For example, a radioactive pollutant with a specified decay rate (or half-life) can be simulated by introducing the following multiplicative term in any concentration equation

$$\exp(-t/T) \quad (16.6.2)$$

where  $t$  is the travel time and  $T$  is the time scale of the decay (easily related to the half-life of the chemical species). Similarly, chemical transformation from a primary to a secondary pollutant (e.g., from gaseous  $\text{SO}_2$  to sulfate particulate matter,  $\text{SO}_4^{2-}$ ) can be accomplished by introducing two exponential terms—  $[\exp(-t/T)]$  and  $[1 - \exp(-t/T)]$  — having the effect of simultaneously decreasing the  $\text{SO}_2$  concentration and increasing the  $\text{SO}_4^{2-}$  concentration as time increases. First-order schemes, though relatively simple, may use parameters that are space and time dependent; for example, the  $\text{SO}_2$ -to-  $\text{SO}_4^{2-}$  conversion rate may vary as a function of relative humidity and solar radiation.

Photochemical smog, which in the past only affected large cities at low latitudes, such as Los Angeles, has become today the most important and common air pollution problem in urban areas throughout the world. Overall, the photochemical smog reactions can be summarized as

where ROG are primary reactive organic gases and  $\text{NO}_x$  include primary NO and mostly secondary  $\text{NO}_2$ . This smog includes carbon monoxide (CO), ozone ( $\text{O}_3$ ), formaldehyde (HCHO), peroxyacetyl nitrate (PAN), nitric acid ( $\text{HNO}_3$ ), particulate matter (PM; especially secondary particles, such as nitrates and organic particles), and other products.

A full chemical reaction scheme is required to simulate complex phenomena, such as the photochemical smog described above, and can be incorporated today only inside Eulerian grids or Lagrangian box models. A typical reaction set, applied in each grid cell at each time step, can be written in terms of linear combinations:

$$\sum_{m=1}^M r_{nm} c_m \Leftrightarrow \sum_{m=1}^M p_{nm} c_m \quad n = 1, 2, \dots, N \quad (16.6.4)$$

where  $M$  species participate in  $N$  reaction steps,  $c_m$  is the concentration of the  $m$ th species, and  $r_{nm}$  and  $p_{nm}$  are numerical constants. Each reaction rate is generally expressed as a product of the concentrations of the species involved, with a temperature-dependent rate constant.

The main difficulty in using Equation (16.6.4) to simulate the photochemical smog is the treatment of **organic compounds**. In fact, due to the very large number, organic species cannot all be included explicitly. Three different types of gas-phase chemical mechanisms are generally used: (1) surrogate mechanisms, which use the chemistry of one or two compounds in each class of organics to represent the chemistry of all species in that class; (2) lumped mechanisms, in which the grouping of chemical compounds is done on the bases of their similar structure and reactivity; and (3) the carbon bond approach, which splits each organic molecule into functional groups using the assumption that the reactivity of the molecule is dominated by the chemistry of each functional group. Each classification technique necessarily introduces a simplification and, therefore, a potential simulation error.

Some key reactions involve the **photolysis** of such species as  $\text{NO}_2$ , HCHO, and nitrous acid (HONO). These one-specie reactions require the calculation of the photolysis rate constant which is a function of, among other things, of solar elevation and temperature.

Aerosol chemistry is particularly difficult to simulate and computationally expensive. However, inclusion of aerosol dynamics within air quality models is of primary importance because of the health effects associated with fine particles in the atmosphere, visibility impairment, and the acid deposition problem. Simple first-order reaction terms can be used to simulate the transformation of  $\text{SO}_2$  into sulfates and  $\text{NO}_x$  into nitrates. These terms can be included in any model. However, a comprehensive simulation of aerosol processes can only be performed within an Eulerian grid or a Lagrangian box model and must include the following fundamental equation of aerosol dynamics (Milford and Russell, 1993) which describes aerosol transport, growth, coagulation, and sedimentation

$$\frac{\delta n}{\delta t} + \nabla \cdot \bar{\mathbf{u}}n + \frac{\delta I}{\delta v} = \frac{1}{2} \int_0^v \beta(\bar{\mathbf{v}}, \mathbf{v} - \bar{\mathbf{v}}) n(\bar{\mathbf{v}}) n(\mathbf{v} - \bar{\mathbf{v}}) d\bar{\mathbf{v}} - \int_0^\infty \beta(\bar{\mathbf{v}}, \mathbf{v}) n(\bar{\mathbf{v}}) n(\mathbf{v}) d\bar{\mathbf{v}} - \nabla \cdot \mathbf{C}n \quad (16.6.5)$$

where  $n$  is the particle size distribution function,  $\bar{\mathbf{u}}$  is the wind velocity,  $I$  is the droplet current that describes particle growth and nucleation due to gas-to-particle conversion,  $v$  is the particle volume,  $\beta$  is the rate of particle coagulation, and  $\mathbf{C}$  is the sedimentation velocity.

The simulation of heterogeneous and aqueous-phase chemistry is of key importance for regional-scale acid deposition and **stratospheric** ozone models, but is usually neglected in urban photochemical applications where the main goal is the simulation of **tropospheric** ozone.

## Deposition

Chemical species are removed from the atmosphere by two mechanisms: reaction and deposition. While chemical reactions may produce new pollutants, deposition is the real process in which the atmosphere cleans itself. Some pollutants are highly reactive and, consequently, have short lifetimes. For example,

ozone has a typical lifetime of 2 min and, therefore, its concentration will drop unless it is continuously regenerated. Other pollutants have longer lifetimes. For example, SO<sub>2</sub> has a typical lifetime of 13 days. Therefore, under certain circumstances, it can easily accumulate during multiday episodes (e.g., the “London” smog). Finally, there are pollutants with very large lifetimes. Because of their low reactivity, they do not cause adverse effects on human health but, nevertheless, can diffuse on a global scale and affect the thermal balance of the Earth. Methane and carbon dioxide are a good example, both with a typical lifetime of 7 years.

Deposition terms can be introduced in any model discussed above. For example, dry deposition can be described by the following formula

$$F_i = V_d c_i \quad (16.6.6)$$

where  $F_i$  is the flux of a species  $i$  to the ground,  $c_i$  is the concentration of the species  $i$  at some reference height (e.g., 1 m), and  $V_d$  is the deposition velocity. The term  $V_d$  has been measured under various meteorological conditions and for a number of surface types (Wesley et al., 1985). Therefore, the calculation of  $F_i$  is straightforward.

Wet deposition (i.e., precipitation scavenging) depends upon the intensity and size of raindrops. Fog and cloud droplets can also absorb gases, capture particles, and accelerate chemical reactions. Wet deposition is quantified by computing the wet flux of pollution to the surface. This calculation requires the estimate of the washout coefficient, which can be inferred (Scott, 1982) as a function of storm type and precipitation amounts.

Because of dry and wet deposition, acidic components such as sulfuric acid particles, particulate nitrate, and nitric acid gas are transferred from the atmosphere to the Earth. Areas which are tens and hundreds of kilometers downwind of large SO<sub>2</sub> and NO<sub>x</sub> sources (e.g., power plants and smelters) suffer the greatest impact.

### Statistical Models

Statistical models are often used in air pollution studies. They include frequency distribution studies, time series analysis, Kalman filters, receptor-modeling techniques, and others. A general distinction between statistical and deterministic approaches is that air pollution deterministic models initiate their calculations at the pollution sources and aim at the establishment of cause/effect relationships, while statistical models are characterized by their direct use of air quality measurements to infer semiempirical relationships. Although very useful, especially for real-time short-term forecasting, statistical models are generally unable to provide cause/effect relationships, with the exception of receptor modeling.

The basic concept of the receptor-modeling approach is the apportionment of the contribution of each source, or group of sources, to the measured concentrations without reconstructing the dispersion pattern and trajectory of the pollutants. Typically, receptor models start with *observed* ambient aerosol concentrations measured at a receptor and seek to apportion the concentrations among several source types (e.g., industrial, transportation, soil, etc.), based on the known chemical composition (i.e., the chemical fractions) of source and receptor materials.

In mathematical notation, the concentration  $c_{ik}$  of the species  $i$  in the  $k$ th sample at a certain monitoring station can be written as

$$c_{ik} = \sum_{j=1}^p a_{ij} D_{jk} E_{jk} \quad (16.6.7)$$

where  $p$  sources (or groups of sources) are assumed to contribute to  $c_{ik}$ ,  $a_{ij}$  is the fractional amount of the component  $i$  in the emission from the  $j$ th source,  $D_{jk}$  is the atmospheric dispersion term, and  $E_{jk}$  is the emission rate (i.e.,  $D_{jk} E_{jk} = S_{jk}$  is the total contribution of the source  $j$  to the  $k$ th sample at the receptor location). Dispersion models assume  $a_{ij}$ ,  $D_{jk}$ , and  $E_{jk}$  to be known (or obtainable from emission and

meteorological data) and estimate the output  $c_{ik}$ . For receptor models, the concentrations  $c_{ik}$  and source “profiles”  $a_{ij}$  are measured instead, and the  $D_{jk}E_{jk}$  products are computed as a model result.

## Ground Water Pollution Modeling

### Saturated Groundwater Flow

The description of the exact movement of fluid particles in a porous medium is difficult (or impossible) as it is not practical to define exactly the flow domain that is described by the geometry of the internal solid surfaces. The problem can be treated at the molecular level, microscopic level, or macroscopic level.

The treatment of the behavior of a system of molecules using theories of classical fluid mechanics is extremely difficult because of the large number of molecules involved and the difficulties in identifying all forces and defining the exact pore geometry. Instead of treating individual molecules, the statistical properties of a very large number of molecules may be inferred from laws governing the motion of individual molecules. Still, this approach will also have similar limitations with respect to the need to define the exact pore geometries. A coarser treatment at the microscopic level where fluid is treated as a continuum is feasible, but most applications in groundwater flow may not require this level of refinement. This approach will also require the accurate definition of the pore geometry.

A coarse level of averaging at the macroscopic level that is referred to as the *representative elementary volume (REV)* is used in most applications in porous media flow analysis. Porous medium is defined as a portion of a space occupied partly by a solid phase (solid matrix) and partly by voids. The voids in general are occupied by one (single phase) or more fluid phases (multiphase). This level of treatment assumes that the solid phase is distributed throughout the problem domain and it should be possible to define an REV such that no matter where we place it within the porous media domain, it will contain both solids and voids.

At the macroscopic scale, the rate at which the water flow in a soil is quantified using a variable that is referred to as the *Darcy velocity* or *specific discharge*. This variable, which has the dimensions of velocity, is defined as the discharge per unit gross area of soil that includes both the pore space and the grains in a flow section. For incompressible fluids a relationship that is referred to as *Darcy’s law* expresses the Darcy velocity in terms of a parameter referred to as hydraulic conductivity,  $K$ , and the gradient of the piezometric head,  $h$ . Darcy’s law for saturated flow (a single fluid filling the pore space) in soils is given by

$$\mathbf{q} = -K\nabla h \quad (16.6.8)$$

where  $\mathbf{q}$  is the specific discharge or Darcy velocity ( $L/T$ ) and  $h$  is the piezometric head ( $L$ ).

In groundwater flow, as the velocities are generally very small, the velocity head is neglected and the driving head becomes the sum of the elevation and the pressure heads. The piezometric head is defined as

$$h = h_z + h_p = z + \frac{p}{\rho g} \quad (16.6.9)$$

where  $\rho$  is the density of water.

In anisotropic aquifers where the hydraulic conductivity changes with flow direction,  $\mathbf{K}$  is a second-rank tensor given as

$$[\mathbf{K}] = \begin{bmatrix} K_{xx} & K_{xy} & K_{xz} \\ K_{yx} & K_{yy} & K_{yz} \\ K_{zx} & K_{zy} & K_{zz} \end{bmatrix} \quad (16.6.10)$$

It can be shown that it is always possible to find three mutually orthogonal directions in space such that

$$K_{ij} \neq 0 \text{ for all } i = j$$

$$K_{ij} = 0 \text{ for all } i \neq j$$

These directions in space are called the principal directions of the anisotropic porous medium. When principal directions are parallel to the axes of the coordinate system, the tensor reduces to a hydraulic conductivity vector given as,

$$[K] = \begin{bmatrix} K_{xx} & 0 & 0 \\ 0 & K_{yy} & 0 \\ 0 & 0 & K_{zz} \end{bmatrix} \quad (16.6.11)$$

For conservation of mass,

$$-\nabla \cdot \rho \mathbf{q} = \frac{\partial n\rho}{\partial t} \quad (16.6.12)$$

For homogeneous, incompressible fluid and a nondeformable porous medium,

$$\nabla \cdot \mathbf{q} = 0 \quad (16.6.13)$$

Introducing head, the mass conservation equation can be written as

$$\nabla \mathbf{q} + S_s \frac{\partial h}{\partial t} = 0 \quad (16.6.14)$$

where  $S_s$  is the specific storage, defined as the volume of water added to storage, per unit volume of porous medium, per unit rise in piezometric head. This is given as

$$S_s = \rho g(\alpha + n\beta) \quad (16.6.15)$$

where  $\beta$  is the compressibility of water and  $\alpha$  is the compressibility of the soil matrix.

Combining Darcy's law and the equation of mass conservation, the general equation of saturated groundwater flow is obtained as

$$\nabla \cdot K \nabla h = S_s \frac{\partial h}{\partial t} \quad (16.6.16)$$

The initial and boundary value problem obtained by combining the above second-order partial differential equation with the initial head in the aquifer and the head or flux conditions at the aquifer boundary is solved to obtain the unknown head in the aquifer. The head distribution can then be used with Darcy's law to obtain the groundwater flow velocity in the aquifer.

### Solute Transport in Groundwater

Transport of dissolved chemicals in aquifers is generally considered to be the result of two processes, namely, advection and dispersion. Advection is the process by which the solute gets transported due to the average motion of water through the intergranular pore spaces of the porous medium. In the mathematical representation of this process in the REV, a macroscopically average velocity that is referred

to as the *average linear pore velocity* is used. An approximate value for this average pore water velocity for granular material based on macroscopic variables is given as

$$v = \frac{q}{n} \quad (16.6.17)$$

where  $n$  is the effective porosity. The average linear pore water velocity is also referred to as the *average solution velocity*.

The advective solute transport is given by

$$\mathbf{J}_a = Cq \quad (16.6.18)$$

where  $\mathbf{J}_a$  is the vector of solute mass flux (mass per unit time per unit area,  $[\text{MT}^{-1}\text{L}^{-2}]$ ) and  $C$  is the mass concentration of solute per unit volume of the solution ( $\text{ML}^{-3}$ ).

Dispersion is the result of two processes that occur in the pore scale, namely, molecular diffusion and mechanical (or hydrodynamic) mixing. Due to molecular diffusion the solute will move from the high-concentration to low-concentration regions in the fluid phase. Fick's first law modified to account for the presence of the solid phase is used to represent the solute flux as a function of the concentration gradient by

$$J_d = -nD_d \cdot \nabla C \quad (16.6.19)$$

where  $J_d$  is diffusive flux,  $[\text{MT}^{-1}\text{L}^{-2}]$ ,  $n$  is the porosity,  $D_d$   $[\text{L}^2\text{T}^{-1}]$ , a second-rank tensor is the effective diffusion coefficient of the solute in the porous medium and  $C$  is the solute concentration,  $[\text{M/L}^{-3}]$ .

The component of dispersion due to mechanical mixing is the result of velocity variation at the microscopic scale. These velocity variations are the result of three basic mechanisms that occur within the pores: (1) viscous shear forces that produce velocity gradients across flow channels, (2) pores size variations produce pore channels with different sizes transmitting water at different pore velocities, and (3) the changing flow directions due to the tortuosity of the flow channels. The combined effect of these variations results in the solute being mixed at the macroscopic scale and producing mass flux along decreasing concentration gradients. As this process is analogous to the diffusion in the microscopic scale, an equation similar to the Fick's first law is used to describe mass flux due to mechanical mixing. This analogous equation is given as

$$J_m = -nD_m \cdot \nabla C \quad (16.6.20)$$

where  $J_m$  is the flux due to mechanical mixing,  $[\text{MT}^{-1}\text{L}^{-2}]$  and  $D_m$  is the coefficient of hydrodynamic (mechanical) dispersion.

The total flux due to molecular diffusion and hydrodynamic dispersion is given as

$$J = J_d + J_m \quad (16.6.21)$$

Substituting for  $J_d$  and  $J_m$ , we have

$$J = -n(D_d + D_m) \cdot \nabla C \quad (16.6.22)$$

Define the dispersion coefficient  $D$  as

$$D = D_d + D_m \quad (16.6.23)$$

Equation (16.6.24) reduces to

$$J = -n(D) \cdot \nabla C \quad (16.6.24)$$

In a three-dimensional system the dispersion coefficient is a second-order tensor that takes the form,

$$[D] = \begin{bmatrix} D_{xx} & D_{xy} & D_{xz} \\ D_{yx} & D_{yy} & D_{yz} \\ D_{zx} & D_{zy} & D_{zz} \end{bmatrix} \quad (16.6.25)$$

By orienting the  $x'$  axes of the local coordinates at the aquifer point along the direction of groundwater flow (longitudinal direction), the dispersion coefficient tensor can be reduced to

$$[D] = \begin{bmatrix} D_{x'x'} & 0 & 0 \\ 0 & D_{y'y'} & 0 \\ 0 & 0 & D_{z'z'} \end{bmatrix} \quad (16.6.26)$$

The local axes  $x'$ ,  $y'$ , and  $z'$  are the principal axes of dispersion and  $D_{x'x'}$ ,  $D_{y'y'}$ , and  $D_{z'z'}$  are the principal values of the coefficient of dispersion. These coefficients can be expressed in terms of the longitudinal average linear pore velocity as

$$D_{x'x'} = D_d + \alpha_L \bar{v}, \quad \text{etc.} \quad (16.6.27)$$

where  $\alpha_L$  and  $\alpha_T$  are longitudinal and lateral dispersion coefficients, respectively. The dispersion coefficients that have dimensions of length can be viewed as characteristic lengths of the porous medium at the pore scale. However, in real applications these values are much larger and have been found to depend on the size of the plume (scale dependent).

Combining advective flux given by Equation (16.6.18) and dispersive flux given by Equation (16.6.24) and applying the principle of mass conservation for the solute, one obtains

$$\frac{\partial(nC)}{\partial t} = \nabla \cdot (nD \cdot \nabla C - Cq) \quad (16.6.28)$$

By substituting the approximation for Darcy's velocity in Equation (16.6.28), the governing equation for solute transport in saturated porous media is obtained as

$$\frac{\partial C}{\partial t} = D \cdot \nabla C - C\bar{v} \quad (16.6.29)$$

The above equation is referred to as the *advection–dispersion equation*. The initial and boundary value problem obtained by combining the above second-order PDE with the initial concentration distribution in the aquifer and the concentration and mass flux at the aquifer boundary is solved to obtain the time and space distribution of the solute concentration in contaminant plumes. It should be noted that to solve the advection–dispersion equation it is necessary to first solve for the groundwater velocities using the groundwater flow equation.

## Surface Water Pollution Transport Modeling

*Ronald R. Hewitt Cohen and Nevis Cook*

The study of water quality modeling bloomed in the late 1960s and through the 1970s. Administrators and bureaucrats with minimal mathematical and science backgrounds were greatly impressed by presentations of pages of PDEs, and model outputs were often treated as absolute truth. As the field and model users matured, it was recognized that a model is just a group of hypotheses about the way the modeler believes the world works, all put in mathematical terms. The limitations, shortcomings, and difficulties with environmental models are well recognized and accepted. Models are now used as *tools* for decision making and planning.

An industrial facility may want to assess how reducing or increasing the mass or concentration of some pollutant in a discharge will impact the receiving waters. It may be that a dramatic, negative impact might be predicted. Reducing the level of pollutant in the discharge may result in little to no improvement to water quality. Obviously, the results of the modeling effort will dictate the level of effort and cost going toward the treatment of the pollutant.

The same facility may be instructed by the USEPA or the state to control discharges such that water quality criteria in the receiving waters are met. Good models can be used to address the question “what are the implications to the receiving waters if various facility process modifications are applied.” Thus, a decision could be made as to the process modifications to be focused upon to match the criteria or standards.

It is not anticipated that every industrial facility has an individual with the capabilities to construct a water quality transport model. There are many models available to run on microcomputers and can be obtained through the USEPA.

## Impact Pathway Methodology

*Ari Rabl and Peter S. Curtiss*

A step beyond conventional dispersion modeling includes the physical and economic impacts of air pollution. Rational management of the environment requires an assessment of the damage caused by pollution. The logically correct way to analyze environmental impacts is the impact pathway methodology whose principal steps are the following:

- Specification of the relevant technologies and the environmental burdens they impose (e.g., kilograms per second of particulates emitted by the plant);
- Calculation of increased pollutant concentration in all affected regions (e.g., micrograms per cubic meter of particulates, using models of atmospheric dispersion and chemistry);
- Calculation of physical impacts (e.g., number of cases of asthma due to these particulates, using a dose–response function);
- In some cases a fourth step may be called for: the economic valuation of these impacts (e.g., multiplication by the cost of a case of asthma).

The numbers are summed over all receptors (population, crops, buildings, ...) that are affected by this pollutant. Formally, the procedure can be represented as an equation for the incremental damage  $D$  due to an incremental quantity  $Q$  of a pollutant emitted by the plant

$$D = \sum_i f_{dr,i} \left( f_{disp-i}(Q) \right) \quad (16.6.30)$$

where  $f_{disp-i}(Q) = c$  = increase in pollutant concentration for receptor  $i$  and  $f_{dr,i}(c)$  = dose–response function for receptor  $i$ ; the summation index  $i$  runs over all receptors (people, crops, buildings, etc.) of concern.

Which receptors are of concern depends on the circumstances. One can distinguish three kinds of situation:

1. Episodic values (typically for litigation after pollution episodes);
2. Peak values (typically for obtaining a permit for a new plant, by showing that impacts are below a damage threshold or regulatory limit);
3. Expectation values (typically for policy applications such as setting of regulations, by showing that average impacts are acceptable).

For the first two of these the summation will typically be over a limited set of receptors, for instance, the residents in a town. For the third application one will usually want to know the total damage, and the sum should cover all receptors that make a significant contribution to the total.

The notation in Equation (16.6.30) allows the possibility that the impact may be different for different individual receptors. This equation expresses the damage in functional form; hence, this methodology is also known under the name *damage function*. Of course, while this methodology is logically correct, the practical implementation may not always be feasible for lack of appropriate data or models.

The dose–response function

$$Y = f_{dr}(X) \quad (16.6.31)$$

relates the quantity  $X$  of a pollutant that affects a receptor (e.g., population) to the physical impact  $Y$  on this receptor (e.g., incremental number of deaths). In the narrow sense of the term,  $X$  should be the dose actually absorbed by a receptor. But often one uses, as we do in the present section, the term dose–response function in the sense of exposure–response function where  $X$  represents the concentration of a pollutant in the ambient air; in that case  $f_{dr}(X)$  accounts implicitly for the absorption of the pollutant from the air into the body. Dose–response functions for the classic air pollutants ( $\text{NO}_x$ ,  $\text{SO}_x$ ,  $\text{O}_3$ , and particulates) are typically of that kind. One can even define aggregated dose–response functions that include more-complicated pathways, for instance, dioxins passing through the food chain, if one interprets the dose–response function to include the aggregated effects of the pathways from a point at the Earth’s surface to all final receptors. In the next sections we take a closer look at the major steps of the methodology.

### The Source Term

The first step of the impact pathway analysis is relatively straightforward. One identifies the site and circumstances of a pollution source, e.g., the tons of  $\text{NO}$  per  $\text{kWhr}_e$  emitted by particular power plant. For the major air pollutants ( $\text{CO}_2$ ,  $\text{CO}$ ,  $\text{NO}$ ,  $\text{SO}_2$ , VOCs, particulate matter) the emission rates for a given technology are quite well known. For the example of power plants the rate of  $\text{CO}_2$  emission is especially well determined. Emissions of  $\text{CO}$ ,  $\text{NO}$ ,  $\text{SO}_2$ , VOCs, and particulate matter are somewhat less certain, and they can vary with operating conditions.  $\text{NO}$  emissions, for instance, are likely to increase above the manufacturer’s specifications if a selective catalytic reduction unit is not well maintained. There are different grades of oil and coal, and their sulfur content can differ by an order of magnitude; obviously, the emissions of  $\text{SO}_2$  depend on the quality of the fuel that will be used. Usually, there are strict regulations that enforce an upper limit on the emissions; due to cost constraints power plants are unlikely to operate significantly below these limits.

The situation is less clear with regard to trace pollutants such as lead and mercury, since their content in different grades of coal can vary by much more than an order of magnitude. Furthermore, some of these pollutants are emitted in such small concentrations that their measurement is difficult. The dirtier the fuel, the greater the uncertainty of emissions. Especially with waste incineration, there has been concern over trace pollutants that are emitted into the air.

Probably the most uncertain emissions are emissions from the disposal and storage of wastes, because they depend on events in the future. Solid waste from coal-fired boilers could be dumped into a simple hole in the ground or it could be placed into an engineered landfill with watertight liners; the possible

impacts will be totally different. There may or may not be a breach of containment, depending on the quality of construction and management and on natural events such as floods or earthquakes. The main risk from a landfill is the leaching of toxic minerals into groundwater; such risk can be kept negligible by proper construction and management.

### Transport Modes

Pollutants can be emitted to air, water, or soil. The majority of pollutants are first emitted into the air, even if they later pass into the water or the soil. Therefore, most of this section focuses on atmospheric dispersion. Transport in the soil is difficult to model because it can involve complex processes that depend on the physical and chemical properties of the soil at each site. Furthermore, for new installations, such as new landfills, the emissions into the soil are not known in advance; they depend on the integrity of the containment structure over the indefinite future.

Transport by surface water, i.e., rivers, lakes, and the sea, is relatively simple to analyze if fine geographical resolution is not required. Thus, one can divide these bodies of water into a reasonably small number of compartments that are treated as uniformly mixed. For example, a river may be divided into ten sections. A differential equation with empirical coefficients relates the concentration in a section under consideration to the concentration in the section immediately upstream and to the emission into this section. Sedimentation, removal, and decay processes are included.

Similarly, for the dispersion into marine waters one uses a compartment model where each compartment communicates with one or several neighbors, and the volumes and flow rates are known. For instance, in a model used for the analysis of nuclear power plants (EC, 1995c), the European seas have been divided into 34 compartments.

For dispersion in the atmosphere, in general both physical and chemical processes need to be considered (Seinfeld, 1986; Zannetti, 1990). Some pollutants, e.g.,  $\text{CO}_2$ ,  $\text{CH}_4$ , and  $^{133}\text{Xe}$ , are sufficiently inert chemically that only the physical transport needs to be analyzed. Some are moderately reactive and their chemical transformation needs to be taken into account.  $\text{SO}_2$ , for instance, leads to the formation of  $\text{SO}_3$ ,  $\text{H}_2\text{SO}_4$  as well as sulfates (the latter from the interaction with  $\text{NH}_3$  emitted by, among others, agricultural activities); this can have significant implications for impact analysis on a regional and global scale.\* Ozone is a secondary pollutant, formed by the combination of  $\text{NO}_x$ , VOC, and light, and the chemistry is extremely complex.

Even though the modeling of the physical transport of pollutants is difficult, it is far simpler than weather modeling. The reason is that pollutants can be considered a small admixture, passively transported by the currents of the surrounding medium. Such transport is linear: the increase in concentration at a receptor site is proportional to the emission (the only exception arises from secondary pollutants such as ozone whose formation depends on other variables, coupled through nonlinear phenomena).

Furthermore, for most policy applications one needs only expectation values of environmental impacts. While it is well known that chaotic phenomena in the atmosphere render the prediction of the weather impossible beyond a short time, this does not prevent the prediction of expectation values. The climate is much more certain than the weather. For expectation values of air pollution damage it suffices to know the average motion of the surrounding medium from past observations, by contrast to weather modeling where that very motion needs to be predicted in detail.

### Transport in Air

A simple model for atmospheric dispersion is the Gaussian plume, discussed earlier. According to this model the concentration of a pollutant is described by the product of two Gaussian distributions, one for the spread in the vertical direction and one for the spread in the horizontal direction perpendicular to the prevailing wind direction. The plume width parameters are based on empirical correlations and take into account the relevant meteorological conditions.

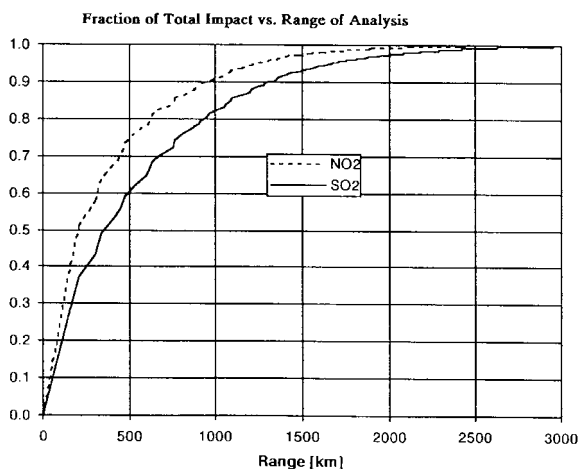

---

\* For example, ammonia sulfate aerosols can reduce the impact of global warming (Charlson and Wigley, 1994).

The Gaussian plume is considered adequate for the short range, up to tens of kilometers from the source, even for episodic events (Zannetti, 1990). The use of this model at distances beyond 100 km is generally not recommended, although it is acceptable for the prediction of the average values if correction terms are included for reflection at the surface and at the PBL of the Earth, and if the depletion mechanisms (deposition, chemical transformation, radioactive decay) are correctly accounted for. As an example of dispersion software based on a Gaussian plume, one can cite the ISC model of the USEPA (Wackter and Foster, 1987).

For regional modeling most analysts prefer to rely on more-detailed computer simulations, for example the Harwell Trajectory Model (1993) or the EMEP model of the Norwegian Meteorological Service (Barrett, 1992; Sandnes, 1993; Iversen, 1993). The latter model is used for the official allocation of acid rain budgets among the countries of Europe.

A crucial question concerns the geographic range over which the analysis needs to be extended in order to capture most of the impacts. This involves a balance among the rates of emission, of dispersion, and of removal of a pollutant. A look at the results of long-range transport models for SO<sub>2</sub> and NO<sub>x</sub>, for instance, those calculated by EMEP (Sandnes, 1993), shows that these pollutants are transported over hundreds, even thousands of kilometers. This is illustrated in Figure 16.6.3 using the EMEP data for a source at Nantes, assuming uniform receptor density and a linear dose–response function. The range of the analysis must be extended to over 1000 km if one wants to capture 80 to 90% of the total impact. The same holds for any air pollutants with comparable removal rate, as has been confirmed explicitly for radionuclides by Kelly and Jones (1985).

**FIGURE 16.6.3** Fraction of total impact vs. range of analysis, for uniform receptor density and linear dose–response function, based on EMEP data (Barrett, 1994). Wiggles are due to discretization.

### Secondary Pollutants

Many pollutants are transformed into secondary pollutants by chemical reactions in the atmosphere. For example, the reactions shown in Figure 16.6.4 create acid rain (wet deposition of H<sub>2</sub>SO<sub>4</sub>) and ammonium sulfate particulates from SO<sub>2</sub>.

Another important secondary pollutant is ozone. It is formed when several chemical reactions take place in sequence. The only reaction that forms ozone directly is

FIGURE 16.6.4 Chemical reactions included in Harwell Trajectory Model. (From EC, 1995c.)

where M is a molecule such as  $N_2$  or  $O_2$  whose participation is necessary to conserve energy and momentum. The oxygen atom involved in the formation of ozone is derived from photolysis of  $NO_2$  under the action of sunlight (indicated by  $h\nu$ )

The presence of VOCs is necessary to prevent the ozone formed from being immediately consumed by NO to produce  $NO_2$  in the following reaction:

VOCs enable the transformation of NO into  $NO_2$  without consuming ozone. Finally, note also that  $NO_2$  plays a double role, since, while being necessary to form ozone, it consumes the radicals needed by VOCs to transform NO into  $NO_2$ . In fact, an equilibrium is created between these reactions. The concentration of ozone therefore is very dependent on changes in the concentrations of other products, and, due to the complexity of the phenomena, it is observed for example that if VOCs are low (as in the case of an electricity power plant plume), the increase in NO may reduce  $O_3$ . Figure 16.6.5 shows the influence of the concentrations of nitrogen oxides and VOCs on the concentration of ozone. In particular, we observe the phenomenon mentioned above: the consequence of an increase in NO on atmospheric ozone depends on the concentration of the organic compounds. The ozone content is also strongly dependent on the  $[NO_2]:[NO]$  ratio. If this ratio is low, the  $[O_3]$  content will remain low.

### Dose–Response Functions

*Form of the Dose–Response Function.* By definition, a dose–response function starts at the origin, and in most cases it increases monotonically with dose  $X$ , as sketched schematically in Figure 16.6.6. At very high doses the function may level off in S-shaped fashion, implying saturation. Dose–response functions are determined from epidemiological studies or from laboratory studies. Since the latter are

**FIGURE 16.6.5** Isoleth plot for the maximum ozone concentration reached during a fixed length of time as a function of initial NO and VOC concentrations. Details of such a plot depend on site and on weather. (From EPRI 1992.)

**FIGURE 16.6.6** Possible behavior of dose–response functions at low doses: the four functions shown have the same value at P. For the function with threshold the discontinuity in slope at the threshold is a simplification; in reality there is a smooth transition.

mostly limited to animals, the extrapolation to humans introduces large uncertainties. Another major difficulty is that one needs relatively high doses in order to obtain observable nonzero responses in a sample of realistic size; such doses are usually far in excess of the levels one is concerned with in environmental impact studies. Thus, there is a serious problem of how to extrapolate from the observed data toward low doses. Figure 16.6.6 indicates several possibilities. The simplest is the linear model, i.e., a straight line from the origin through the observed data point(s). Cancer from radioactivity is an example. Linearity also seems to be observed for mortality from fine particulates (Dockery et al., 1993; Dockery and Pope, 1994; Lipfert, 1994).

Another possibility is a straight line down to some threshold, and zero effect below that threshold. Thresholds occur when an organism has a natural repair mechanism that can prevent or counteract damage up to a certain limit. Many dose–response functions for noncancer toxicity are of this type.

There is even the possibility of a “fertilizer effect” at low doses, as indicated by the dashed line in Figure 16.6.6. This can be observed, for example, in the dose–response functions for the impact of NO<sub>x</sub> and SO<sub>x</sub> on crops: a low dose of these pollutants can increase the crop yield; in other words, the damage

is negative. Such a fertilizer effect can occur with pollutants that provide trace elements needed by an organism. It depends on local conditions, in particular the overall balance of nutrients. The fertilizer effect illustrates the link between the understanding of the underlying processes and the choice of the appropriate form for the dose–response function: since N and S are known to be important nutrients for plants, a functional form like the dashed line in Figure 16.6.6 is the most plausible.

If nothing is known about a threshold and a fertilizer effect can be ruled out, the dose–response function could be anywhere between zero and the straight line through the origin, for instance, the curved solid line shown in Figure 16.6.6. *A priori* there is no general rule about the extrapolation to low doses, other than there being no known cases of a dose–response function above the straight line. There is even a case where the same substance causes different cancers according to different dose–response functions, one with and one without threshold. This was established in an experiment (sometimes referred to as the megamouse experiment) in which some 24,000 mice were exposed to the carcinogen 2-acetyl-amino-fluorene at several different dose levels (Frith et al., 1981). The response for liver tumor is linear, whereas the one for bladder tumor has a threshold.

### Site Dependence of Marginal Impacts

From here on we limit ourselves to the important case where the dose–response function  $f_{dr}(\mathbf{x}, c(\mathbf{x}))$  can be approximated by

$$f_{dr}(\mathbf{x}, c(\mathbf{x})) \approx d(\mathbf{x})c(\mathbf{x}) \quad \text{where} \quad d(\mathbf{x}) = \frac{df_{dr}(\mathbf{x}, c(\mathbf{x}))}{dc} \quad (16.6.32)$$

is the slope of the dose–response function. With that assumption one can write the damage in the form

$$D = \int dx \int dy r(\mathbf{x})d(\mathbf{x})c(\mathbf{x}) \quad (16.6.33)$$

This is obviously exact for any pollutant whose dose–response function is linear, or a straight line with a threshold that is everywhere below the background. It is also valid, regardless of dose–response function, for the evaluation of any marginal impacts, i.e., impacts from small pollutant increments because in that case one can linearize the dose–response function. Since  $c(\mathbf{x})$  is linear in the emission, it follows that Equation (16.6.33), and the remainder of this section, are equally applicable to steady-state situations and to emissions that vary with time.

It is instructive to relate the concentration  $c(\mathbf{x})$  to the removal rate of the pollutant. There are essentially three mechanisms by which an air pollutant can disappear from the atmosphere (Seinfeld 1986):

1. dry deposition (uptake at the Earth’s surface by soil, water, or vegetation);
2. wet deposition (absorption into droplets followed by droplet removal by precipitation);
3. decay or transformation (e.g., decay of radionuclides or chemical transformation of  $\text{SO}_2$  to  $(\text{NH}_4)_2\text{SO}_4$ ).

When evaluating the damage of the original pollutant, this pollutant is no longer counted in the equation once it has been transformed; rather from that point on a different dose–response function comes into play for the secondary pollutant. That issue will be addressed below.

The dry deposition rate is proportional to the concentration  $c(\mathbf{x})$  at the Earth’s surface, and it is customarily written in the form

$$F_{\text{dry}}(\mathbf{x}) = v_{\text{dry}}c(\mathbf{x}) \quad (16.6.34)$$

where  $F_{\text{dry}}(\mathbf{x})$  = deposition flux (in  $\text{kg}/\text{m}^2\text{-sec}$ ) and  $v_{\text{dry}}$  = dry deposition velocity (m/sec).

Wet deposition and decay or transformation can likewise be characterized in terms of fluxes  $F_{\text{wet}}(\mathbf{x})$  and  $F_{\text{trans}}(\mathbf{x})$ , defined as the rate at which the pollutant is removed by these mechanisms per square meter and per second. Even though in general these fluxes are not proportional to the surface concentration but rather to the average concentration in the air column above  $x$ , we can write the total removal flux,

$$F(\mathbf{x}) = F_{\text{dry}}(\mathbf{x}) + F_{\text{wet}}(\mathbf{x}) + F_{\text{trans}}(\mathbf{x}) \quad (16.6.35)$$

in terms of the surface concentration  $c(\mathbf{x})$  as

$$F(\mathbf{x}) = k(\mathbf{x})c(\mathbf{x}) \quad (16.6.36)$$

if we allow the proportionality constant  $k(\mathbf{x})$  to vary with  $\mathbf{x}$ . The units of  $k$  are m/sec, and it could be called removal velocity. Using  $F(\mathbf{x})$  and  $k(\mathbf{x})$ , we can write the damage in the form:

$$D = \int dx \int dy r(\mathbf{x}) d(\mathbf{x}) F(\mathbf{x}) / k(\mathbf{x}) \quad (16.6.37)$$

This equation is exact if we interpret Equation (16.6.36) as the definition of  $k(\mathbf{x})$ .

If the world were homogeneous, with uniform receptor density  $r(\mathbf{x}) = r_{\text{uni}}$ , uniform dose–response function slope  $d(\mathbf{x}) = d_{\text{uni}}$ , and uniform removal velocity  $k(\mathbf{x}) = k_{\text{uni}}$ , the integral in Equation (16.6.37) would be simply

$$D = D_{\text{uni}} = d_{\text{uni}} r_{\text{uni}} Q / k_{\text{uni}} \quad (16.6.38)$$

because the surface integral of the removal flux equals the emission

$$Q = \int dx \int dy F(\mathbf{x}) \quad (16.6.39)$$

by conservation of matter.

Even though the assumption  $k(\mathbf{x}) = k_{\text{uni}}$  may not appear very realistic, especially near a point source, the sensitivity to deviations from uniformity turns out to be surprisingly small, as we will demonstrate below in [Figure 16.6.7](#). The reason is that for typical values of atmospheric dispersion parameters the total impact is dominated by regions sufficiently far from the source that the pollutant can be considered to be vertically well mixed in the PBL, at least as far as expectation values are concerned.

Thus, the simple Equation (16.6.38) can be a useful first estimate, good to an order of magnitude or better, independent of the details of atmospheric dispersion (Curtiss and Rabl, 1996b). It is intuitively plausible that the damage is proportional to the slope  $d$  of the dose–response function, to the density  $r$  of receptors, and to the emission rate  $Q$ . Furthermore, it is inversely proportional to the removal velocity  $k$ . If there were no removal mechanism, the pollutant concentration would increase without limit and the damage would be infinite. This approach can also be adapted for the damage due to a secondary pollutant.

To verify the relevance of Equation (16.6.38) we compare it with real site-dependent results, calculated with the PATHWAYS software package (Curtiss and Rabl, 1995; Curtiss and Rabl, 1996c), which carries out an accurate numerical integration of atmospheric dispersion results over geographic data for population and other receptors. To add substance to the results, we consider a specific impact: the increase in mortality due to  $\text{SO}_2$  emitted by coal-fired power plants. The dose–response function (based on Sunyer et al., 1996) is linear and can be written in the form:

$$\Delta \text{deaths per year per person} = 5.34 \times \Delta \text{PM}_{10} \text{ concentration (in g/m}^3\text{)} \quad (16.6.40)$$

**Example**

We consider an annual SO<sub>2</sub> output of Q = 1000 ton/year = 30 g/sec. For the atmospheric dispersion we take a curve fit to the EMEP data for a grid cell in the center of France, which yields a removal velocity k = 0.01 m/sec. Inserting Q = 30.9 g/sec, k<sub>uni</sub> = 0.01 m/sec, d<sub>uni</sub> = 5.34 (deaths/year)/(g/m<sup>3</sup>) and r<sub>uni</sub> = 1.05 × 10<sup>-4</sup> m<sup>-2</sup> (for France) into Equation (16.6.38), we obtain

$$D_{\text{uni}} = \frac{5.34 \text{ deaths}/(\text{person} \cdot \text{yr})/(\text{g}/\text{m}^3) \times 1.05\text{E-}4 \text{ persons}/\text{m}^2 \times 30.9 \text{ g}/\text{sec}}{0.01 \text{ m}/\text{sec}} = 1.78 \text{ deaths}/\text{yr}$$

This number is shown as the thick solid line in Figure 16.6.7, where the number of deaths per year is plotted vs. emission height h<sub>e</sub>. The points, connected by lines, show the impacts for five specific sites. We have chosen these sites because there are in fact fossil fuel power plants at these sites (the nearest big city, 25 to 50 km away, is indicated in parentheses). Although the real emissions at the different sites are different, here we have assumed the emissions of the Cordemais plant at all sites to bring out the point of the comparison. The impact is about 2 to 6 times larger than D<sub>uni</sub> for the site near Paris and about 0.4 to 0.5 times D<sub>uni</sub> for Cordemais, a rural site on the Atlantic Ocean. We also see that there is little variation with stack height.

**FIGURE 16.6.7** An example of dependence on site and on height of source: mortality from particulate matter from a coal-fired power plant, for five sites in France and for uniform world model (Equation (16.6.38)). Annual SO<sub>2</sub> emission 1000 ton/year.

**Analysis of Uncertainties**

By contrast to the relatively small uncertainties and normal (Gaussian) frequency distributions typically encountered in science and engineering, the uncertainties in impact analysis are so large that it would be inappropriate to use error intervals that are additively symmetric about the mean. Instead, one should specify multiplicative intervals, in other words, intervals that are additive on a logarithmic scale. The frequency distributions are not symmetric, with implications that may appear counterintuitive to people

not accustomed to them. It is helpful to think in terms of lognormal distributions because they are frequently encountered in impact analysis, analogous to the normal distributions so familiar in the more exact sciences. A variable  $x$  has a lognormal distribution if the variable  $\ln(x)$  has a normal distribution; in other words, it is normal on a logarithmic scale.

Analogous to the ordinary normal (also known as Gaussian) distribution, which is characterized by two parameters, the mean and the standard deviation, the lognormal distribution can be characterized by the geometric mean and the geometric standard deviation  $s_G$ . For this distribution the geometric mean is equal to the median: half of the distribution is above, the other half below the median. The geometric standard has a simple interpretation in terms of the 68% confidence interval (a familiar number because for Gaussian distributions 68% of all values are within one standard deviation of the mean): for a lognormal distribution 68% of the values are within the interval  $(1/s_G, s_G)$ . Likewise, 95% are within the interval  $[(1/s_G)^2, (s_G)^2]$ . Note, however, that these values are centered around the median rather than the mean; the lognormal distribution is not symmetric. For impacts of primary air pollutants with relatively well-determined dose–response functions, e.g., mortality due to particulates,  $s_G$  may be as small as 3. For other impacts, e.g., cancers due to dioxins, the uncertainties could be an order of a magnitude or more.

It is appropriate to note that technical or scientific uncertainties (e.g., uncertainties of emitted quantities or of dose–response functions) are not the only ones. For long-term impacts, such as cancers caused by radioactive waste, one needs to make assumptions about scenarios for the future: what quantities of radionuclides will leak into the environment and how many people will be affected by them. For the estimation of damage costs, there is also the matter of policy/ethical choice, e.g., about discount rate and value of human life.

## 16.7 Global Climate Change

---

*Frank Kreith*

There is consensus in the scientific community that continuing the emission of CO<sub>2</sub> and other “greenhouse” gases (methane, nitrous oxide, ozone, and chlorofluorocarbons or CFCs) into the atmosphere at current rates will lead to a warming of the Earth. General circulation models of the atmosphere indicate that a doubling of CO<sub>2</sub> concentration in the atmosphere will trap sufficient solar radiation to increase the average global temperature by the middle of the 21st century at least 2°C, but possibly as much as 5°C according to the Congressional Research Service (Morrison, 1989). Although critics of these projections argue that the available models do not accurately portray the potential feedback mechanisms from clouds and oceans to warming, and question the amount, timing, and location of the temperature increase, there is agreement that greenhouse gases trap radiation and increase the global temperature. The latest international scientific assessment concluded that “evidence suggests that there is a discernible human influence on global climate” (Watson et al., 1995).

Despite uncertainty over the magnitude, timing, and potential impacts of global warming, there is general agreement that those policies and technologies that reduce the emission of greenhouse gases and have no adverse economic impact should be implemented now. Highest priorities relate to energy conservation, improved efficiency in energy generation, emission reduction from transportation, reforestation, and phasing out of CFCs (see Chapter 9). These proposed actions represent challenges to many facets of mechanical engineering.

### Technical Background

The greenhouse effect is a natural phenomenon and one of the most well established theories in atmospheric science (see [Figure 16.7.1](#)). Most of the solar radiation impinging on Earth is in the frequency range below 3 μm. Radiation in this frequency band can readily penetrate Earth’s atmosphere and is absorbed by the Earth. But most of the thermal radiation emitted by the Earth is infrared, i.e., in a frequency range above 3 μm, which is partly absorbed and reflected by the atmosphere. Gases in the atmosphere thus prevent part of the radiation emitted by the Earth from escaping into space and trap enough radiation to maintain our climate equilibrium. The atmosphere acts like the glass windows in a greenhouse — hence, the name *greenhouse effect*. Without this effect the Earth would be about 60°F cooler and life as we know it would not exist.

[Figure 16.7.2](#) shows the distribution of the gases in the atmosphere that participate in the greenhouse effect, as well as the industrial sectors emitting them. An increase in the amount of atmospheric greenhouse gases increases the amount of radiation absorbed by the atmosphere and thus reduces the amount of radiation emitted by the Earth that can pass into space. This causes warming of the Earth. Carbon dioxide is the principal greenhouse gas, responsible for over one half of the predicted warming of the Earth. Most of the generation of CO<sub>2</sub> results from the burning of fossil fuels. Its primary sources are electric utilities (33%), transportation (31%), industrial processes (24%), and heating and cooling of buildings (12%). Methane, CFCs, ozone, and nitrous oxide constitute the balance of greenhouse emission. Carbon dioxide emissions have increased globally by 25% since the industrial revolution 200 years ago, and there has been an over 10% increase in the last 30 years alone. In the same period, methane concentration has more than doubled (from 800 to 1700 ppb).

Temperature records compiled by the United Kingdom Meteorological Office indicate that the Earth’s average temperature has risen roughly 1°F since 1860 (see [Figure 16.7.3](#)). Since CO<sub>2</sub> is the principal greenhouse gas, estimating its growth is important for future prediction of climate change. Although all fossil fuels emit CO<sub>2</sub> when burned, their emission per unit energy produced is not equal. Natural gas is the cleanest fossil fuel. Oil combustion emits between 38 and 43% more CO<sub>2</sub> than natural gas, whereas coal combustion contains from 72 to 95% more CO<sub>2</sub> per unit energy released than natural gas. Ocean

**FIGURE 16.7.1** Schematic diagram of the greenhouse effect.

and trees act as carbon sinks because they absorb  $\text{CO}_2$ . Trees absorb  $\text{CO}_2$  during the process of photosynthesis. Deforestation is important because it not only eliminates a mitigating factor of global warming, but when wood is burned, it too emits carbon dioxide directly into the atmosphere.

### Potential Impacts of Global Climate Change

In its 1989 report to Congress, the USEPA sought to identify the impacts of global warming on specific geographic areas. The agency used simulations from three general circulation models — Goddard Institute for Space Studies (GISS), Geophysical Fluids Dynamics Laboratory (GFDL), and Oregon State University (OSU) — to project the effects of climate change on four regions: Southeast, Great Lakes, Great Plains, and California. The three models are in general agreement that a doubling of carbon dioxide in the atmosphere will increase the temperature, but they differ in magnitude, predicting between 3 and 5°C. Although they concur that annual precipitation will increase, their regional projections vary — the GFDL model predicts reduced precipitation in the Southeast, the GISS in the Great Plains, and the OSU in California. The report acknowledges, however, that the reliability of these regional predictions is limited.

The USEPA assessment of the potential impact of climate change on natural resources and the environment has serious implications for forests, agriculture, water resources, biodiversity, and sea-level rise. The southern boundary of forest species is expected to move northward and drier soils could alter the plant composition with grasslands and hardwoods replacing commercially valuable conifers. Also, fire and pest disturbances could become more frequent. Agricultural productivity would shift northward, causing economic dislocations for farmers in southern states.

One of the most important effects of global warming is a rise in sea level resulting from melting glaciers. Projections of future sea-level rise range from 0.3 to 1.1 m (1 to 3.5 ft) by the end of the next century. A 1-m rise could flood between 26 and 60% of the nation's coastal wetlands and cost up to \$100 billion to protect developed areas that would otherwise be flooded.

**FIGURE 16.7.2** Greenhouse gas profile. (From U.S. Environmental Protection Agency, 1989.)

### Mitigation Options for Global Warming

There is general agreement that an initial global warming will result from increases in greenhouse gases in the atmosphere, and the position of the U.S. Government, according to the Office of Science and Technology Policy issued in 1996, is that “we collectively must redouble our efforts in identifying the most cost-effective global approaches to reduce emissions in both the near- and long-term utilizing a broad portfolio of actions.” However, the scientific uncertainty regarding the timing and severity of future climate impacts and their consequences creates a policy dilemma of what actions should be taken.

**FIGURE 16.7.3** Global temperature change since 1860. Variation of annual surface temperatures for the world. The solid line shows long-term trends. The planet has warmed an average of almost 1° F. (From United Kingdom Meteorological Office, 1989.)

Because measures to limit greenhouse gas emission require efforts lasting many years and could affect the economic health of a country, the costs of climate policy and the technical means of achieving emission reduction must be considered with the focus on obtaining the largest reduction in potential greenhouse warming at the lowest cost to society. To date, CO<sub>2</sub> from combustion of fossil fuels has been the primary focus of attention. A comprehensive look at mitigation options, however, must consider the emission of all greenhouse gases to compare the relative importance of different emissions. The concept of a global warming potential to estimate the CO<sub>2</sub>-equivalent emission of each of the major greenhouse gases is useful. Table 16.7.1 shows an estimate of greenhouse gas emissions from various human activities.

Various scenarios of the CO<sub>2</sub>-equivalent reduction achievable by various mitigation measures have been studied. The various mitigation measures were grouped into two categories. The “best practice” technology options shown in Table 16.7.2 can be implemented now at no cost or even at net savings, but they are not used because of institutional and other barriers. Additional options shown in Table 16.7.3 either cost money or have benefits that are not readily quantified or face other implementation obstacles. In this study, no forecasts or scenarios for the future were used, but the results were applied to a 1989 base year.

Inspection of Table 16.7.2 indicates that improved energy efficiency in residential and commercial buildings will reduce demand for fossil fuel and, thereby, also reduce emissions. Conservation measures that reduce the use of electric power are the most significant. For example, improved commercial lighting to reduce the energy consumption by about 45% would not only save money, but if installed in commercial buildings, would result in electricity savings of about 10% from space-conditioning requirements.

The potential for reducing electricity consumption in the industrial sector with currently available technology is about 30%. A case study of energy-intensive industries such as steel mills and petrochemical plants indicates that energy savings of the order of 25 to 30% in direct industrial fuel use may be available economically by investing in more-efficient furnaces, energy recovery systems, and other process equipment. Also, increased use of cogeneration technologies would produce cost-effective CO<sub>2</sub> reductions as shown in Table 16.7.2.

The other important sector in which large reductions in greenhouse gas emissions can be achieved is transportation. These reductions in greenhouse gas emissions are largely through improved fuel economy and better transportation management methods that reduce traffic congestion (see Section 10, Transportation).

Mitigation measures outside the energy sector involve landfills, CFC use, agricultural activity, and forests. For example, the collection and combustion of landfill gas could reduce methane emission by about 65%. For a discussion of the other mitigation methods, the reader is referred to the original studies cited.

**TABLE 16.7.1 Estimate of Current Greenhouse Gas Emissions from Human Activity**

Source	Annual Emissions (Mt/year) <sup>a</sup>		CO <sub>2</sub> -Equivalent (Mt/year) <sup>a</sup>	
	World	U.S.	World	U.S.
<i>CO<sub>2</sub> emissions</i>				
Commercial energy	18,800		18,800

Fuel and industrial biomass	0.2		60	
<b>Total N<sub>2</sub>O</b>	<b>4.0</b>	<b>1.4</b>	<b>1,180</b>	<b>410</b>
<b>Overall total</b>			<b>32,880</b>	<b>7,900</b>

<sup>a</sup> Millions of metric tons based on the estimated global warming potential (GWP) for a 100-year averaging time (6): CO<sub>2</sub> = 1, CH<sub>4</sub> = 21, N<sub>2</sub>O = 290, CFC-11 = 3500, CFC-12 = 7300 and CFC-113 = 4200. Values give the CO<sub>2</sub>-equivalent radiative forcing for an instantaneous injection of 1 kg of gas into the atmosphere. Values for CH<sub>4</sub> include the estimated indirect effects of CO<sub>2</sub> produced. However, the GWP does not incorporate complex couplings with other greenhouse gases such as stratospheric and tropospheric ozone and their precursor emissions. The GWP thus provides only a preliminary basis for comparing diverse mitigation strategies.

HFC (auto air conditioning) <sup>q</sup>	170	5
HFC (refrigerators)	11	11
HCFC (other refrigeration) <sup>r</sup>	67	4
HCFC/HFC (refrigerator insulation)	14	28
<b>Sector total</b>	<b>1409</b>	<b>1.4 (0.9/3)</b>

**TABLE 16.7.3 Additional Mitigation Options that are Costly or that have Significant Other Benefits or Costs that are not Readily Quantified. Some of these Options would Face Serious Implementation Obstacles because of Such Factors (continued)**

Mitigation Option	CO <sub>2</sub> -Equivalent Reduction <sup>a</sup>	Net Cost <sup>b</sup>
<i>Domestic agriculture</i>		
Nitrogenous fertilizers <sup>s</sup>	126	2.5
Paddy rice <sup>t</sup>	23	0.5
Ruminant animals <sup>u</sup>	84	2.0
<b>Sector total</b>	<b>223</b>	<b>2 (1/5)</b>
Reforestation <sup>v</sup>	242	7 (3/10)
<i>Other options</i>		
New industrial technology <sup>w</sup>	300	?
New transportation fuels <sup>x</sup>	1130	?

<sup>a</sup> Equivalent CO<sub>2</sub> reduction in millions of metric tons based on 1989 fuel and electricity use. <sup>b</sup>Net implemented cost in dollars per ton of CO<sub>2</sub>-equivalent. Includes direct costs only. Many of these measures have additional indirect costs that could be significant (see text). Values are mid-range cost estimates based on a 6% real discount rate, constant 1989 dollars. Values in parentheses give low/high range for average cost for real discount rates of 3 to 10% plus uncertainty across different studies or estimates. <sup>c</sup>Switch current coal consumption in industrial plants to natural gas or oil where technically feasible (estimated at 0.6 quadrillion Btu). <sup>d</sup>Estimate 25% of employer-provided parking spaces and tax remaining spaces to reduce solo commuting by 15 to 20%. <sup>e</sup>Improve on-road fuel economy from 32.5 to 46.8 mpg (CAFE) with additional technology measures and downsizing that require changes in the existing fleet mix. <sup>f</sup>Implement improved fan jet and other technologies to improve fuel efficiency by 20%. <sup>g</sup>Potential emission reductions apply only to one technology at a time and are not cumulative. All cost-effectiveness estimates are relative to existing (1989) coal plants. <sup>h</sup>Based on advanced pulverized coal plants. <sup>i</sup>Based on the use of combined cycle systems in place of coal. Co-firing natural gas at existing coal-fired plants has similar costs but lower reduction potential. <sup>j</sup>Based on advanced light-water reactors replacing current fossil-fuel capacity for baseload and intermediate load operation. <sup>k</sup>Based on replacing all fossil fuel plants in the 1989 generating mix. Replacement of coal plants only yields 1470 Mt/year. Remaining potential after maximum demand reductions and plant upgrades is 950 Mt/year. <sup>l</sup>Includes chlorofluorocarbons (CFC), hydrofluorocarbons (HFC), and hydrochlorofluorocarbons (HCFC). <sup>m</sup>Modify or replace existing equipment to use non-CFC materials as cleaning and blowing agents, aerosols, and refrigerants where technically possible. <sup>n</sup>Upgrade equipment and retrain personnel to improve conservation and recycling of CFCs. <sup>o</sup>Substitute cleaning and blowing agents and aerosols with fluorocarbon substitutes. <sup>p</sup>Retrofit or replace all existing chillers to use fluorocarbon substitutes. <sup>q</sup>Replace existing automobile air conditioners with equipment using fluorocarbon substitutes. <sup>r</sup>Replace commercial refrigeration equipment such as used in supermarkets and transportation with equipment using fluorocarbon substitutes. <sup>s</sup>Reduce nitrogenous fertilizer use by 5%. <sup>t</sup>Eliminate all U.S. paddy rice production. <sup>u</sup>Reduce ruminant animal production by 25%. <sup>v</sup>Reforest 28.7 Mha of economically or environmentally marginal crop and pasture lands and nonfederal forest lands. <sup>w</sup>Increase recycling and reduce energy consumption primarily in the primary metals, pulp and paper, chemicals, and petroleum refining industries through new, less energy intensive technology. <sup>x</sup>Based on replacement of highway transport fuels with alternative fuels that emit no greenhouse gases.

## Defining Terms

**Aerosol:** Small solid particle or liquid droplet suspended in the air.

**Anthropogenic:** Man-made.

**Deterministic:** Dealing with cause and effect.

**Ensemble average:** Theoretical average, i.e., the value that could be expected as the average from an infinite number of realizations.

**Global warming:** The warming of the earth as a result of the atmosphere which traps solar radiation. Currently, the term global warming is used to denote the temperature increase due to carbon dioxide, methane and other greenhouse gases.

**Greenhouse Gases:** Carbon dioxide, methane and other gases resulting from human activities that increase the amount of solar radiation trapped by the atmosphere.

**Numerical advection errors:** Numerical errors generated by finite-difference solutions of transport terms using an Eulerian grid model.

**Organic compounds:** Chemical species containing one or more carbon atoms.

**Photochemical:** Chemical reactions influenced by light.

**Photolysis:** Chemical decomposition by the action of light.

**Planetary boundary layer, PBL:** The atmospheric layer which is affected by the momentum and heat fluxes generated by the Earth surface (typically, the first 500–1000 m of the atmosphere).

**Stratospheric:** Related to the stratosphere, the portion of the atmosphere approximately between 10 to 50 km above the ground.

**Tropospheric:** Related to the troposphere, the lower level of the atmosphere approximately from the surface to 10 km above.

**Wind shear:** The change in wind speed and direction as a function of height.

### Greek Alphabet

Greek Letter	Greek Name	English Equivalent	Greek Letter	Greek Name	English Equivalent
A α	Alpha	a	N ν	Nu	n
B β	Beta	b	Ξ ξ	Xi	x
Γ γ	Gamma	g	Ο ο	Omicron	o
Δ δ	Delta	d	Π π	Pi	p
E ε	Epsilon	e	Ρ ρ	Rho	r
Z ζ	Zeta	z	Σ σ ς	Sigma	s
H η	Eta	e	T τ	Tau	t
Θ θ ϑ	Theta	th	Υ υ	Upsilon	u
I ι	Iota	i	Φ φ ϕ	Phi	ph
K κ	Kappa	k	Χ χ	Chi	ch
Λ λ	Lambda	l	Ψ ψ	Psi	ps
M μ	Mu	m	Ω ω	Omega	o

### International System of Units (SI)

The International System of units (SI) was adopted by the 11th General Conference on Weights and Measures (CGPM) in 1960. It is a coherent system of units built from seven *SI base units*, one for each of the seven dimensionally independent base quantities: the meter, kilogram, second, ampere, kelvin, mole, and candela, for the dimensions length, mass, time, electric current, thermodynamic temperature, amount of substance, and luminous intensity, respectively. The definitions of the SI base units are given below. The *SI derived units* are expressed as products of powers of the base units, analogous to the corresponding relations between physical quantities but with numerical factors equal to unity.

In the International System there is only one SI unit for each physical quantity. This is either the appropriate SI base unit itself or the appropriate SI derived unit. However, any of the approved decimal prefixes, called *SI prefixes*, may be used to construct decimal multiples or submultiples of SI units.

It is recommended that only SI units be used in science and technology (with SI prefixes where appropriate). Where there are special reasons for making an exception to this rule, it is recommended always to define the units used in terms of SI units. This section is based on information supplied by IUPAC.

### Definitions of SI Base Units

*Meter:* The meter is the length of path traveled by light in vacuum during a time interval of  $1/299\,792\,458$  of a second (17th CGPM, 1983).

*Kilogram:* The kilogram is the unit of mass; it is equal to the mass of the international prototype of the kilogram (3rd CGPM, 1901).

*Second:* The second is the duration of  $9\,192\,631\,770$  periods of the radiation corresponding to the transition between the two hyperfine levels of the ground state of the cesium-133 atom (13th CGPM, 1967).

*Ampere:* The ampere is that constant current which, if maintained in two straight parallel conductors of infinite length, of negligible circular cross section, and placed 1 meter apart in vacuum, would produce between these conductors a force equal to  $2 \times 10^{-7}$  newton per meter of length (9th CGPM, 1958).

*Kelvin:* The kelvin, unit of thermodynamic temperature, is the fraction  $1/273.16$  of the thermodynamic temperature of the triple point of water (13th CGPM, 1967).

*Mole:* The mole is the amount of substance of a system which contains as many elementary entities as there are atoms in 0.012 kilogram of carbon-12. When the mole is used, the elementary entities must be specified and may be atoms, molecules, ions, electrons, or other particles, or specified groups of such particles (14th CGPM, 1971). Examples of the use of the mole:

- 1 mol of  $\text{H}_2$  contains about  $6.022 \times 10^{23}$   $\text{H}_2$  molecules, or  $12.044 \times 10^{23}$  H atoms.
- 1 mol of  $\text{HgCl}$  has a mass of 236.04 g.
- 1 mol of  $\text{Hg}_2\text{Cl}_2$  has a mass of 472.08 g.
- 1 mol of  $\text{Hg}_2^{2+}$  has a mass of 401.18 g and a charge of 192.97 kC.
- 1 mol of  $\text{Fe}_{0.91}\text{S}$  has a mass of 82.88 g.
- 1 mol of  $e^-$  has a mass of 548.60  $\mu\text{g}$  and a charge of  $-96.49$  kC.
- 1 mol of photons whose frequency is  $10^{14}$  Hz has energy of about 39.90 kJ.

*Candela:* The candela is the luminous intensity, in a given direction, of a source that emits monochromatic radiation of frequency  $540 \times 10^{12}$  Hz and that has a radiant intensity in that direction of  $(1/683)$  watt per steradian (16th CGPM, 1979).

### Names and Symbols for the SI Base Units

Physical Quantity	Name of SI Unit	Symbol for SI Unit
Length	meter	m
Mass	kilogram	kg
Time	second	s
Electric current	ampere	A
Thermodynamic temperature	kelvin	K
Amount of substance	mole	mol
Luminous intensity	candela	cd

### SI Derived Units with Special Names and Symbols

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Frequency <sup>a</sup>	hertz	Hz	$\text{s}^{-1}$
Force	newton	N	$\text{m} \cdot \text{kg} \cdot \text{s}^{-2}$
Pressure, stress	pascal	Pa	$\text{N} \cdot \text{m}^{-2} = \text{m}^{-1} \cdot \text{kg} \cdot \text{s}^{-2}$
Energy, work, heat	joule	J	$\text{N} \cdot \text{m} = \text{m}^2 \cdot \text{kg} \cdot \text{s}^{-2}$
Power, radiant flux	watt	W	$\text{J} \cdot \text{s}^{-1} = \text{m}^2 \cdot \text{kg} \cdot \text{s}^{-3}$
Electric charge	coulomb	C	$\text{A} \cdot \text{s}$

Physical Quantity	Name of SI Unit	Symbol for SI Unit	Expression in Terms of SI Base Units
Electric potential, electromotive force	volt	V	$J \cdot C^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-1}$
Electric resistance	ohm	$\Omega$	$V \cdot A^{-1} = m^2 \cdot kg \cdot s^{-3} \cdot A^{-2}$
Electric conductance	siemens	S	$\Omega^{-1} = m^{-2} \cdot kg^{-1} \cdot s^4 \cdot A^2$
Electric capacitance	farad	F	$C \cdot V^{-1} = m^{-2} \cdot kg^{-1} \cdot s^4 \cdot A^2$
Magnetic flux density	tesla	T	$V \cdot s \cdot m^{-2} = kg \cdot s^{-2} \cdot A^{-1}$
Magnetic flux	weber	Wb	$V \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-1}$
Inductance	henry	H	$V \cdot A^{-1} \cdot s = m^2 \cdot kg \cdot s^{-2} \cdot A^{-2}$
Celsius temperature <sup>b</sup>	degree Celsius	$^{\circ}C$	K
Luminous flux	lumen	lm	cd · sr
Illuminance	lux	lx	cd · sr · m <sup>-2</sup>
Activity (radioactive)	becquerel	Bq	s <sup>-1</sup>
Absorbed dose (or radiation)	gray	Gy	$J \cdot kg^{-1} = m^2 \cdot s^{-2}$
Dose equivalent (dose equivalent index)	sievert	Sv	$J \cdot kg^{-1} = m^2 \cdot s^{-2}$
Plane angle	radian	rad	$1 = m \cdot m^{-1}$
Solid angle	steradian	sr	$1 = m^2 \cdot m^{-2}$

<sup>a</sup> For radial (circular) frequency and for angular velocity the unit rad s<sup>-1</sup>, or simply s<sup>-1</sup>, should be used, and this may not be simplified to Hz. The unit Hz should be used only for frequency in the sense of cycles per second.

<sup>b</sup> The Celsius temperature  $\theta$  is defined by the equation

$$q/^{\circ}C = T/K = 237.15$$

The SI unit of Celsius temperature interval is the degree Celsius,  $^{\circ}C$ , which is equal to the kelvin, K.  $^{\circ}C$  should be treated as a single symbol, with no space between the  $^{\circ}$  sign and the letter C. (The symbol  $^{\circ}K$ , and the symbol  $^{\circ}$ , should no longer be used.)

## Units in Use Together with the SI

These units are not part of the SI, but it is recognized that they will continue to be used in appropriate contexts. SI prefixes may be attached to some of these units, such as milliliter, ml; millibar, mbar; mega-electronvolt, MeV; and kilotonne, kt.

Physical Quantity	Name of Unit	Symbol for Unit	Value in SI Units
Time	minute	min	60 s
Time	hour	h	3600 s
Time	day	d	86 400 s
Plane angle	degree	$^{\circ}$	$(\pi/180)$ rad
Plane angle	minute	'	$(\pi/10\ 800)$ rad
Plane angle	second	"	$(\pi/648\ 000)$ rad
Length	angstrom <sup>a</sup>	$\text{\AA}$	$10^{-10}$ m
Area	barn	b	$10^{-28}$ m <sup>2</sup>
Volume	liter	l, L	$dm^3 = 10^{-3}$ m <sup>3</sup>
Mass	tonne	t	$Mg = 10^3$ kg
Pressure	bar <sup>a</sup>	bar	$10^5$ Pa = $10^5$ N · m <sup>-2</sup>
Energy	electronvolt <sup>b</sup>	eV (= $e \times V$ )	$\approx 1.60218 \times 10^{-19}$ J
Mass	unified atomic mass unit <sup>b,c</sup>	u (= $m_u(12C)/12$ )	$\approx 1.66054 \times 10^{-27}$ kg

<sup>a</sup> The angstrom and the bar are approved by CIPM for "temporary use with SI units," until CIPM makes a further recommendation. However, they should not be introduced where they are not used at present.

<sup>b</sup> The values of these units in terms of the corresponding SI units are not exact, since they depend on the values of the physical constants  $e$  (for the electronvolt) and  $N_A$  (for the unified atomic mass unit), which are determined by experiment.

<sup>c</sup> The unified atomic mass unit is also sometimes called the dalton, with symbol Da, although the name and symbol have not been approved by CGPM.

## Conversion Constants and Multipliers

### Recommended Decimal Multiples and Submultiples

Multiple or Submultiple	Prefix	Symbol	Multiple or Submultiple	Prefix	Symbol
10 <sup>18</sup>	exa	E	10 <sup>-1</sup>	deci	d

## Temperature Factors

$$^{\circ}\text{F} = 9/5(^{\circ}\text{C}) + 32$$

$$\text{Fahrenheit temperature} = 1.8(\text{temperature in kelvins}) - 459.67$$

$$^{\circ}\text{C} = 5/9[(^{\circ}\text{F}) - 32]$$

$$\text{Celsius temperature} = \text{temperature in kelvins} - 273.15$$

$$\text{Fahrenheit temperature} = 1.8(\text{Celsius temperature}) + 32$$

### Conversion of Temperatures

From	To		From	To	
Fahrenheit	Celsius	$t_C = \frac{t_F - 32}{1.8}$	Celsius	Fahrenheit	$t_F = (t_C \times 1.8) + 32$
				Kelvin	$T_K = t_C + 273.15$
	Kelvin	$T_K = \frac{t_F - 32}{1.8} + 273.15$	Kelvin	Rankine	$T_R = (t_C + 273.15) \times 18$
				Celsius	$t_C = T_K - 273.15$
	Rankine	$T_R = t_F + 459.67$		Rankine	$T_R = T_K \times 1.8$
			Rankine	Fahrenheit	$t_F = T_R - 459.67$
				Kelvin	$T_K = \frac{T_R}{1.8}$

### Physical Constants

#### General

- Equatorial radius of the earth = 6378.388 km = 3963.34 miles (statute)
- Polar radius of the earth = 6356.912 km = 3949.99 miles (statute)
- 1 degree of latitude at 40° = 69 miles
- 1 international nautical mile = 1.150 78 miles (statute) = 1852 m = 6076.115 ft
- Mean density of the earth = 5.522 g/cm<sup>3</sup> = 344.7 lb/ft<sup>3</sup>
- Constant of gravitation (6.673 ± 0.003) × 10<sup>-8</sup> · cm<sup>3</sup> · g<sup>-1</sup> · s<sup>-2</sup>
- Acceleration due to gravity at sea level, latitude 45° = 980.6194 cm/s<sup>2</sup> = 32.1726 ft/s<sup>2</sup>
- Length of seconds pendulum at sea level, latitude 45° = 99.3575 cm = 39.1171 in.
- 1 knot (international) = 101.269 ft/min = 1.6878 ft/s = 1.1508 miles (statute)/h
- 1 micron = 10<sup>-4</sup> cm
- 1 angstrom = 10<sup>-8</sup> cm
- Mass of hydrogen atom = (1.673 39 ± 0.0031) × 10<sup>-24</sup> g
- Density of mercury at 0°C = 13.5955 g/mL
- Density of water at 3.98°C = 1.000 000 g/mL
- Density, maximum, of water, at 3.98°C = 0.999 973 g/cm<sup>3</sup>
- Density of dry air at 0°C, 760 mm = 1.2929 g/L
- Velocity of sound in dry air at 0°C = 331.36 m/s = 1087.1 ft/s
- Velocity of light in vacuum = (2.997 925 ± 0.000 002) × 10<sup>10</sup> cm/s
- Heat of fusion of water, 0°C = 79.71 cal/g
- Heat of vaporization of water, 100°C = 539.55 cal/g
- Electrochemical equivalent of silver 0.001 118 g/s international amp
- Absolute wavelength of red cadmium light in air at 15°C, 760 mm pressure = 6438.4696 Å
- Wavelength of orange-red line of krypton 86 = 6057.802 Å

#### π Constants

- π = 3.14159 26535 89793 23846 26433 83279 50288 41971 69399 37511

## Symbols and Terminology for Physical and Chemical Quantities

Name	Symbol	Definition	SI Unit
<b>Classical Mechanics</b>			
Mass	$m$		kg
Reduced mass	$\mu$	$\mu = m_1 m_2 / (m_1 + m_2)$	kg
Density, mass density	$\rho$	$\rho = m/V$	$\text{kg} \cdot \text{m}^{-3}$
Relative density	$d$	$d = \rho/\rho^0$	1
Surface density	$\rho_A, \rho_S$	$\rho_a = m/A$	$\text{kg} \cdot \text{m}^{-2}$
Specific volume	$v$	$v = V/m = 1/\rho$	$\text{m}^3 \cdot \text{kg}^{-1}$
Momentum	$p$	$p = mv$	$\text{kg} \cdot \text{m} \cdot \text{s}^{-1}$
Angular momentum, action	$L$	$L = r \times p$	$\text{J} \cdot \text{s}$
Moment of inertia	$I, J$	$I = \sum m_i r_i^2$	$\text{kg} \cdot \text{m}^2$
Force	$F$	$F = d p/d t = m a$	N
Torque, moment of a force	$T, (M)$	$T = r \times F$	$\text{N} \cdot \text{m}$
Energy	$E$		J
Potential energy	$E_p, V, \Phi$	$E_p = \int F \cdot ds$	J
Kinetic energy	$E_k, T, K$	$E_k = (1/2) mv^2$	J
Work	$W, w$	$W = \int F \cdot ds$	J
Hamilton function	$H$	$H(q,p) = T(q,p) + V(q)$	J
Lagrange function	$L$	$L(q, \dot{q}) = T(q, \dot{q}) - V(q)$	J
Pressure	$p, P$	$p = F/A$	$\text{Pa}, \text{N} \cdot \text{m}^{-2}$
Surface tension	$\gamma, \sigma$	$\gamma = dW/dA$	$\text{N} \cdot \text{m}^{-1}, \text{J} \cdot \text{m}^{-1}$
Weight	$G (W, P)$	$G = mg$	N
Gravitational constant	$G$	$F = Gm_1 m_2 / r^2$	$\text{N} \cdot \text{m}^2 \cdot \text{kg}^{-2}$
Normal stress	$\sigma$	$\sigma = F/A$	Pa
Shear stress	$\tau$	$\tau = F/A$	Pa
Linear strain, relative elongation	$\epsilon, e$	$\epsilon = \Delta l/l$	1
Modulus of elasticity, Young's modulus	$E$	$E = \sigma/\epsilon$	Pa
Shear strain	$\gamma$	$\gamma = \Delta x/d$	1
Shear modulus	$G$	$G = \tau/\gamma$	Pa
Volume strain, bulk strain	$\theta$	$\theta = \Delta V/V_0$	1
Bulk modulus, compression modulus	$K$	$K = V_0(dp/dV)$	Pa
Viscosity, dynamic viscosity	$\eta, \mu$	$\tau_{x,z} = \eta(dv_x/dz)$	$\text{Pa} \cdot \text{s}$
Fluidity	$\phi$	$\phi = 1/\eta$	$\text{m} \cdot \text{kg}^{-1} \cdot \text{s}$
Kinematic viscosity	$\nu$	$\nu = \eta/\rho$	$\text{m}^2 \cdot \text{s}^{-1}$
Friction coefficient	$\mu, (f)$	$F_{\text{frict}} = \mu F_{\text{norm}}$	1
Power	$P$	$P = dW/dt$	W
Sound energy flux	$P, P_a$	$P = dE/dt$	W
Acoustic factors			
Reflection factor	$\rho$	$\rho = P_r/P_0$	1
Acoustic absorption factor	$\alpha_a, (\alpha)$	$\alpha_a = 1 - \rho$	1
Transmission factor	$\tau$	$\tau = P_t/P_0$	1
Dissipation factor	$\delta$	$\delta = \alpha_a - \tau$	1

Name	Symbol	Definition	SI Unit
<b>Classical Mechanics</b>			
<b>Electricity and Magnetism</b>			
Quantity of electricity, electric charge	Q		C
Charge density	$\rho$	$\rho = Q/V$	$C \cdot m^{-3}$
Surface charge density	$\sigma$	$\sigma = Q/A$	$C \cdot m^{-2}$
Electric potential	$V, \phi$	$V = dW/dQ$	$V, J \cdot C^{-1}$
Electric potential difference	$U, \Delta V, \Delta\phi$	$U = V_2 - V_1$	V
Electromotive force	E	$E = \int(F/Q) \cdot ds$	V
Electric field strength	E	$E = F/Q = -\text{grad } V$	$V \cdot m^{-1}$
Electric flux	$\psi$	$\psi = \int D \cdot dA$	C
Electric displacement	D	$D = \epsilon E$	$C \cdot m^{-2}$
Capacitance	C	$C = Q/U$	$F, C \cdot V^{-1}$
Permittivity	$\epsilon$	$D = \epsilon E$	$F \cdot m^{-1}$
Permittivity of vacuum	$\epsilon_0$	$\epsilon_0 = \mu_0^{-1} c_0^{-2}$	$F \cdot m^{-1}$
Relative permittivity	$\epsilon_r$	$\epsilon_r = \epsilon/\epsilon_0$	1
Dielectric polarization (dipole moment per volume)	P	$P = D - \epsilon_0 E$	$C \cdot m^{-2}$
Electric susceptibility	$\chi_e$	$\chi_e = \epsilon_r - 1$	1
Electric dipole moment	$p, \mu$	$P = QR$	$C \cdot m$
Electric current	I	$I = dQ/dt$	A
Electric current density	$j, J$	$I = \int j \cdot dA$	$A \cdot m^{-2}$
Magnetic flux density, magnetic induction	B	$F = Qv \times B$	T
Magnetic flux	$\Phi$	$\Phi = \int B \cdot dA$	Wb
Magnetic field strength	H	$B = \mu H$	$A \cdot m^{-1}$
Permeability	$\mu$	$B = \mu H$	$N \cdot A^{-2}, H \cdot m^{-1}$
Permeability of vacuum	$\mu_0$		$H \cdot m^{-1}$
Relative permeability	$\mu_r$	$\mu_r = \mu/\mu_0$	1
Magnetization (magnetic dipole moment per volume)	M	$M = B/\mu_0 - H$	$A \cdot m^{-1}$
Magnetic susceptibility	$\chi, \kappa, (\chi_m)$	$\chi = \mu_r - 1$	1
Molar magnetic susceptibility	$\chi_m$	$\chi_m = V_m \chi$	$m^3 \cdot \text{mol}^{-1}$
Magnetic dipole moment	$m, \mu$	$E_p = -m \cdot B$	$A \cdot m^2, J \cdot T^{-1}$
Electrical resistance	R	$R = U/I$	$\Omega$
Conductance	G	$G = 1/R$	S
Loss angle	$\delta$	$\delta = (\pi/2) + \phi_I - \phi_U$	1, rad
Reactance	X	$X = (U/I) \sin \delta$	$\Omega$
Impedance (complex impedance)	Z	$Z = R + iX$	$\Omega$
Admittance (complex admittance)	Y	$Y = 1/Z$	S
Susceptance	B	$Y = G + iB$	S
Resistivity	$\rho$	$\rho = E/j$	$\Omega \cdot m$
Conductivity	$\kappa, \gamma, \sigma$	$\kappa = 1/\rho$	$S \cdot m^{-1}$
Self-inductance	L	$E = -L(dI/dt)$	H
Mutual inductance	$M, L_{12}$	$E_1 = L_{12}(dI_2/dt)$	H
Magnetic vector potential	A	$B = \nabla \times A$	$Wb \cdot m^{-1}$
Poynting vector	S	$S = E \times H$	$W \cdot m^{-2}$
<b>Electromagnetic Radiation</b>			
Wavelength	$\lambda$		m
Speed of light			
In vacuum	$c_0$		$m \cdot s^{-1}$
In a medium	c	$c = c_0/n$	$m \cdot s^{-1}$
Wavenumber in vacuum	$\tilde{\nu}$	$\tilde{\nu} = \nu/c_0 = 1/n\lambda$	$m^{-1}$
Wavenumber (in a medium)	$\sigma$	$\sigma = 1/\lambda$	$m^{-1}$
Frequency	$\nu$	$\nu = c/\lambda$	Hz
Circular frequency, pulsance	$\omega$	$\omega = 2\pi\nu$	$s^{-1}, \text{rad} \cdot s^{-1}$
Refractive index	n	$n = c_0/c$	1
Planck constant	h		$J \cdot s$

Name	Symbol	Definition	SI Unit
<b>Classical Mechanics</b>			
Planck constant/ $2\pi$	$\bar{h}$	$\bar{h} = h/2\pi$	J · s
Radiant energy	$Q, W$		J
Radiant energy density	$\rho, w$	$\rho = Q/V$	J · m <sup>-3</sup>
Spectral radiant energy density			
In terms of frequency	$\rho_\nu, w_\nu$	$\rho_\nu = d\rho/d\nu$	J · m <sup>-3</sup> · Hz <sup>-1</sup>
In terms of wavenumber	$\rho_{\tilde{\nu}}, w_{\tilde{\nu}}$	$\rho_\nu = d\rho/d\tilde{\nu}$	J · m <sup>-2</sup>
In terms of wavelength	$\rho_\lambda, w_\lambda$	$\rho_\lambda = d\rho/d\lambda$	J · m <sup>-4</sup>
Einstein transition probabilities			
Spontaneous emission	$A_{nm}$	$dN_n/dt = -A_{nm}N_n$	s <sup>-2</sup>
Stimulated emission	$B_{nm}$	$dN_n/dt = -\rho_\nu(\tilde{\nu}_{nm}) \times B_{nm}N_n$	s · kg <sup>-1</sup>
Stimulated absorption	$B_{nm}$	$dN_n/dt = \rho_\nu(\tilde{\nu}_{nm}) B_{nm}N_n$	s · kg <sup>-1</sup>
Radiant power, radiant energy per time	$\Phi, P$	$\Phi = dQ/dt$	W
Radiant intensity	$I$	$I = d\Phi/d\Omega$	W · sr <sup>-1</sup>
Radiant exitance (emitted radiant flux)	$M$	$M = d\Phi/dA_{\text{source}}$	W · m <sup>-2</sup>
Irradiance (radiant flux received)	$E, (I)$	$E = d\Phi/dA$	W · m <sup>-2</sup>
Emittance	$\varepsilon$	$\varepsilon = M/M_{\text{bb}}$	1
Stefan-Boltzmann constant	$\sigma$	$M_{\text{bb}} = \sigma T^4$	W · m <sup>-2</sup> · K <sup>-4</sup>
First radiation constant	$c_1$	$c_1 = 2\pi^5hc_0^2/15$	W · m <sup>-2</sup>

## Elementary Algebra and Geometry

---

### Fundamental Properties (Real Numbers)

$a + b = b + a$	Commutative law for addition
$(a + b) + c = a + (b + c)$	Associative law for addition
$a + 0 = 0 + a$	Identity law for addition
$a + (-a) = (-a) + a = 0$	Inverse law for addition
$a(bc) = (ab)c$	Associative law for multiplication
$a\left(\frac{1}{a}\right) = \left(\frac{1}{a}\right)a = 1, a \neq 0$	Inverse law for multiplication
$(a)(1) = (1)(a) = a$	Identity law for multiplication
$ab = ba$	Commutative law for multiplication
$a(b + c) = ab + ac$	Distributive law

Division by zero is not defined.

### Exponents

For integers  $m$  and  $n$ ,

$$a^n a^m = a^{n+m}$$

$$a^n / a^m = a^{n-m}$$

$$(a^n)^m = a^{nm}$$

$$(ab)^m = a^m b^m$$

$$(a/b)^m = a^m / b^m$$

### Fractional Exponents

$$a^{p/q} = (a^{1/q})^p$$

where  $a^{1/q}$  is the positive  $q$ th root of  $a$  if  $a > 0$  and the negative  $q$ th root of  $a$  if  $a$  is negative and  $q$  is odd. Accordingly, the five rules of exponents given above (for integers) are also valid if  $m$  and  $n$  are fractions, provided  $a$  and  $b$  are positive.

### Irrational Exponents

If an exponent is irrational (e.g.,  $\sqrt{2}$ ), the quantity, such as  $a^{\sqrt{2}}$ , is the limit of the sequence  $a^{1.4}, a^{1.41}, a^{1.414}, \dots$

### Operations with Zero

$$0^m = 0 \quad a^0 = 1$$

### Logarithms

If  $x$ ,  $y$ , and  $b$  are positive  $b \neq 1$ ,

$$\log_b(xy) = \log_b x + \log_b y$$

$$\log_b(x/y) = \log_b x - \log_b y$$

$$\log_b x^p = p \log_b x$$

$$\log_b(1/x) = -\log_b x$$

$$\log_b b = 1$$

$$\log_b 1 = 0 \quad \text{Note: } b^{\log_b x} = x$$

### Change of Base ( $a \neq 1$ )

$$\log_b x = \log_a x \log_b a$$

### Factorials

The factorial of a positive integer  $n$  is the product of all the positive integers less than or equal to the integer  $n$  and is denoted  $n!$ . Thus,

$$n! = 1 \cdot 2 \cdot 3 \cdot \cdots \cdot n$$

Factorial 0 is defined:  $0! = 1$ .

### Stirling's Approximation

$$\lim_{n \rightarrow \infty} \left( \frac{n}{e^n} \right)^n \sqrt{2\pi n} = n!$$

### Binomial Theorem

For positive integer  $n$

$$(x + y)^n = x^n + nx^{n-1}y + \frac{n(n-1)}{2!}x^{n-2}y^2 + \frac{n(n-1)(n-2)}{3!}x^{n-3}y^3 + \cdots + nxy^{n-1} + y^n$$

### Factors and Expansion

$$(a + b)^2 = a^2 + 2ab + b^2$$

$$(a - b)^2 = a^2 - 2ab + b^2$$

$$(a + b)^3 = a^3 + 3a^2b + 3ab^2 + b^3$$

$$(a - b)^3 = a^3 - 3a^2b + 3ab^2 - b^3$$

$$(a^2 - b^2) = (a - b)(a + b)$$

$$(a^3 - b^3) = (a - b)(a^2 + ab + b^2)$$

$$(a^3 + b^3) = (a + b)(a^2 - ab + b^2)$$

## Progression

An *arithmetic progression* is a sequence in which the difference between any term and the preceding term is a constant ( $d$ ):

$$a, a + d, a + 2d, \dots, a + (n - 1)d$$

If the last term is denoted  $l [= a + (n - 1)d]$ , then the sum is

$$s = \frac{n}{2}(a + l)$$

A *geometric progression* is a sequence in which the ratio of any term to the preceding term is a constant  $r$ . Thus, for  $n$  terms,

$$a, ar, ar^2, \dots, ar^{n-1}$$

The sum is

$$S = \frac{a - ar^n}{1 - r}$$

## Complex Numbers

A complex number is an ordered pair of real numbers  $(a, b)$ .

*Equality:*  $(a, b) = (c, d)$  if and only if  $a = c$  and  $b = d$

*Addition:*  $(a, b) + (c, d) = (a + c, b + d)$

*Multiplication:*  $(a, b)(c, d) = (ac - bd, ad + bc)$

The first element  $(a, b)$  is called the *real* part, the second the *imaginary* part. An alternative notation for  $(a, b)$  is  $a + bi$ , where  $i^2 = (-1, 0)$ , and  $i = (0, 1)$  or  $0 + 1i$  is written for this complex number as a convenience. With this understanding,  $i$  behaves as a number, that is,  $(2 - 3i)(4 + i) = 8 + 2i - 12i - 3i^2 = 11 - 10i$ . The conjugate of a  $a + bi$  is  $a - bi$ , and the product of a complex number and its conjugate is  $a^2 + b^2$ . Thus, *quotients* are computed by multiplying numerator and denominator by the conjugate of the denominator, as illustrated below:

$$\frac{2 + 3i}{4 + 2i} = \frac{(4 - 2i)(2 + 3i)}{(4 - 2i)(4 + 2i)} = \frac{14 + 8i}{20} = \frac{7 + 4i}{10}$$

## Polar Form

The complex number  $x + iy$  may be represented by a plane vector with components  $x$  and  $y$ :

$$x + iy = r(\cos\theta + i\sin\theta)$$

(See Figure 19.1.1.). Then, given two complex numbers  $z_1 = \tau_1(\cos\theta_1 + i\sin\theta_1)$  and  $z_2 = \tau_2(\cos\theta_2 + i\sin\theta_2)$ , the product and quotient are:

Product:  $z_1 z_2 = r_1 r_2 [\cos(\theta_1 + \theta_2) + i \sin(\theta_1 + \theta_2)]$

Quotient:  $z_1 / z_2 = (r_1 / r_2) [\cos(\theta_1 - \theta_2) + i \sin(\theta_1 - \theta_2)]$

Powers:  $z^n = [r(\cos \theta + i \sin \theta)]^n = r^n [\cos n\theta + i \sin n\theta]$

Roots:  $z^{1/n} = [r(\cos \theta + i \sin \theta)]^{1/n}$   
 $= r^{1/n} \left[ \cos \frac{\theta + k \cdot 360}{n} + i \sin \frac{\theta + k \cdot 360}{n} \right]$   
 $k = 0, 1, 2, \dots, n - 1$

FIGURE 19.1.1 Polar form of complex number.

### Permutations

A permutation is an ordered arrangement (sequence) of all or part of a set of objects. The number of permutations of  $n$  objects taken  $r$  at a time is

$$p(n, r) = n(n - 1)(n - 2) \cdots (n - r + 1)$$

$$= \frac{n!}{(n - r)!}$$

A permutation of positive integers is “even” or “odd” if the total number of inversions is an even integer or an odd integer, respectively. Inversions are counted relative to each integer  $j$  in the permutation by counting the number of integers that follow  $j$  and are less than  $j$ . These are summed to give the total number of inversions. For example, the permutation 4132 has four inversions: three relative to 4 and one relative to 3. This permutation is therefore even.

### Combinations

A combination is a selection of one or more objects from among a set of objects regardless of order. The number of combinations of  $n$  different objects taken  $r$  at a time is

$$C(n, r) = \frac{P(n, r)}{r!} = \frac{n!}{r!(n - r)!}$$

## Algebraic Equations

### Quadratic

If  $ax^2 + bx + c = 0$ , and  $a \neq 0$ , then roots are

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}$$

### Cubic

To solve  $\mathbf{x}^2 + bx^2 + cx + d = 0$ , let  $x = y - b/3$ . Then the *reduced cubic* is obtained:

$$y^3 + py + q = 0$$

where  $p = c - (1/3)b^2$  and  $q = d - (1/3)bc + (2/27)b^3$ . Solutions of the original cubic are then in terms of the reduced cubic roots  $y_1, y_2, y_3$ :

$$x_1 = y_1 - (1/3)b \quad x_2 = y_2 - (1/3)b \quad x_3 = y_3 - (1/3)b$$

The three roots of the reduced cubic are

$$y_1 = (A)^{1/3} + (B)^{1/3}$$

$$y_2 = W(A)^{1/3} + W^2(B)^{1/3}$$

$$y_3 = W^2(A)^{1/3} + W(B)^{1/3}$$

where

$$A = -\frac{1}{2}q + \sqrt{(1/27)p^3 + \frac{1}{4}q^2}$$

$$B = -\frac{1}{2}q - \sqrt{(1/27)p^3 + \frac{1}{4}q^2}$$

$$W = \frac{-1 + i\sqrt{3}}{2}, \quad W^2 = \frac{-1 - i\sqrt{3}}{2}$$

When  $(1/27)p^3 + (1/4)q^2$  is negative,  $A$  is complex; in this case  $A$  should be expressed in trigonometric form:  $A = r(\cos \theta + i \sin \theta)$  where  $\theta$  is a first or second quadrant angle, as  $q$  is negative or positive. The three roots of the reduced cubic are

$$y_1 = 2(r)^{1/3} \cos(\theta/3)$$

$$y_2 = 2(r)^{1/3} \cos\left(\frac{\theta}{3} + 120^\circ\right)$$

$$y_3 = 2(r)^{1/3} \cos\left(\frac{\theta}{3} + 240^\circ\right)$$

### Geometry

Figures 19.1.2 to 19.1.12 are a collection of common geometric figures. Area ( $A$ ), volume ( $V$ ), and other measurable features are indicated.

FIGURE 19.1.2 Rectangle.  $A = bh$ .

-

## Integrals

### Elementary Forms (Add an arbitrary constant to each integral)

$$1. \int a \, dx = ax$$

$$2. \int a \cdot f(x) \, dx = a \int f(x) \, dx$$

$$3. \int \phi(y) \, dx = \int \frac{\phi(y)}{y'} \, dy, \quad \text{where } y' = \frac{dy}{dx}$$

$$4. \int (u + v) \, dx = \int u \, dx + \int v \, dx, \quad \text{where } u \text{ and } v \text{ are any functions of } x$$

$$5. \int u \, dv = u \int dv - \int v \, du = uv - \int v \, du$$

$$6. \int u \frac{dv}{dx} \, dx = uv - \int v \frac{du}{dx} \, dx$$

$$7. \int x^n \, dx = \frac{x^{n+1}}{n+1}, \quad \text{except } n = -1$$

$$8. \int \frac{f'(x) \, dx}{f(x)} = \log f(x), \quad [df(x) = f'(x) \, dx]$$

$$9. \int \frac{dx}{x} = \log x$$

$$10. \int \frac{f'(x) \, dx}{2\sqrt{f(x)}} = \sqrt{f(x)}, \quad [df(x) = f'(x) \, dx]$$

$$11. \int e^x \, dx = e^x$$

$$12. \int e^{ax} \, dx = e^{ax}/a$$

$$13. \int b^{ax} \, dx = \frac{b^{ax}}{a \log b}, \quad (b > 0)$$

$$14. \int \log x \, dx = x \log x - x$$

$$15. \int a^x \log a \, dx = a^x, \quad (a > 0)$$

$$16. \int \frac{dx}{a^2 + x^2} = \frac{1}{a} \tan^{-1} \frac{x}{a}$$

$$17. \int \frac{dx}{a^2 - x^2} = \begin{cases} \frac{1}{a} \tan^{-1} \frac{x}{a} \\ \text{or} \\ \frac{1}{2a} \log \frac{a+x}{a-x}, \quad (a^2 > x^2) \end{cases}$$

$$18. \int \frac{dx}{x^2 - a^2} = \begin{cases} -\frac{1}{a} \operatorname{ctnh}^{-1} \frac{x}{a} \\ \text{or} \\ \frac{1}{2a} \log \frac{x-a}{x+a}, \quad (x^2 > a^2) \end{cases}$$

$$19. \int \frac{dx}{\sqrt{a^2 - x^2}} = \begin{cases} \sin^{-1} \frac{x}{|a|} \\ \text{or} \\ -\cos^{-1} \frac{x}{|a|}, \quad (a^2 > x^2) \end{cases}$$

$$20. \int \frac{dx}{\sqrt{x^2 \pm a^2}} = \log(x + \sqrt{x^2 \pm a^2})$$

$$21. \int \frac{dx}{x\sqrt{x^2 - a^2}} = \frac{1}{|a|} \sec^{-1} \frac{x}{|a|}$$

$$22. \int \frac{dx}{x\sqrt{a^2 \pm x^2}} = -\frac{1}{a} \log\left(\frac{a + \sqrt{a^2 \pm x^2}}{x}\right)$$

### Forms Containing $(a + bx)$

For forms containing  $a + bx$ , but not listed in the table, the substitution  $u = (a + bx)x$  may prove helpful.

$$23. \int (a + bx)^n dx = \frac{(a + bx)^{n+1}}{(n+1)b}, \quad (n \neq -1)$$

$$24. \int x(a + bx)^n dx = \frac{1}{b^2(n+2)}(a + bx)^{n+2} - \frac{a}{b^2(n+1)}(a + bx)^{n+1}, \quad (n \neq -1, -2)$$

$$25. \int x^2(a + bx)^n dx = \frac{1}{b^3} \left[ \frac{(a + bx)^{n+3}}{n+3} - 2a \frac{(a + bx)^{n+2}}{n+2} + a^2 \frac{(a + bx)^{n+1}}{n+1} \right]$$

$$26. \int x^m(a + bx)^n dx = \begin{cases} \frac{x^{m+1}(a + bx)^n}{m+n+1} + \frac{an}{m+n+1} \int x^m(a + bx)^{n-1} dx \\ \text{or} \\ \frac{1}{a(n+1)} \left[ -x^{m+1}(a + bx)^{n+1} + (m+n+2) \int x^m(a + bx)^{n+1} dx \right] \\ \text{or} \\ \frac{1}{b(m+n+1)} \left[ x^m(a + bx)^{n+1} - ma \int x^{m-1}(a + bx)^n dx \right] \end{cases}$$

$$27. \int \frac{dx}{a + bx} = \frac{1}{b} \log(a + bx)$$

$$28. \int \frac{dx}{(a + bx)^2} = -\frac{1}{b(a + bx)}$$

$$29. \int \frac{dx}{(a + bx)^3} = -\frac{1}{2b(a + bx)^2}$$

$$30. \int \frac{x dx}{a + bx} = \begin{cases} \frac{1}{b^2} [a + bx - a \log(a + bx)] \\ \text{or} \\ \frac{x}{b} - \frac{a}{b^2} \log(a + bx) \end{cases}$$

$$31. \int \frac{x dx}{(a + bx)^2} = \frac{1}{b^2} \left[ \log(a + bx) + \frac{a}{a + bx} \right]$$

32.  $\int \frac{x \, dx}{(a+bx)^n} = \frac{1}{b^2} \left[ \frac{-1}{(n-2)(a+bx)^{n-2}} + \frac{a}{(n-1)(a+bx)^{n-1}} \right], \quad n \neq 1, 2$
33.  $\int \frac{x^2 \, dx}{a+bx} = \frac{1}{b^3} \left[ \frac{1}{2}(a+bx)^2 - 2a(a+bx) + a^2 \log(a+bx) \right]$
34.  $\int \frac{x^2 \, dx}{(a+bx)^2} = \frac{1}{b^3} \left[ a+bx - 2a \log(a+bx) - \frac{a^2}{a+bx} \right]$
35.  $\int \frac{x^2 \, dx}{(a+bx)^3} = \frac{1}{b^3} \left[ \log(a+bx) + \frac{2a}{a+bx} - \frac{a^2}{2(a+bx)^2} \right]$
36.  $\int \frac{x^2 \, dx}{(a+bx)^n} = \frac{1}{b^3} \left[ \frac{-1}{(n-3)(a+bx)^{n-3}} + \frac{2a}{(n-2)(a+bx)^{n-2}} - \frac{a}{(n-1)(a+bx)^{n-1}} \right], \quad n \neq 1, 2, 3$
37.  $\int \frac{dx}{x(a+bx)} = -\frac{1}{a} \log \frac{a+bx}{x}$

39.  $\int \frac{dx}{x(a+bx)^3} = \frac{1}{a^3} \left[ \frac{1}{2} \left( \frac{2a+bx}{a+bx} \right)^2 + \log \frac{x}{a+bx} \right]$
40.  $\int \frac{dx}{x^2(a+bx)} = -\frac{1}{ax} + \frac{b}{a^2} \log \frac{a+bx}{x}$
41.  $\int \frac{dx}{x^3(a+bx)} = \frac{2bx-a}{2a^2x^2} + \frac{b^2}{a^3} \log \frac{x}{a+bx}$
42.  $\int \frac{dx}{x^2(a+bx)^2} = -\frac{a+2bx}{a^2x(a+bx)} + \frac{2b^2}{a^3} \log \frac{a+bx}{x}$

## The Fourier Transforms

For a piecewise continuous function  $F(x)$  over a finite interval  $0 \leq x \leq \pi$ , the *finite Fourier cosine transform* of  $F(x)$  is

$$f_c(n) = \int_0^\pi F(x) \cos nx \, dx \quad (n = 0, 1, 2, \dots) \quad (19.1.1)$$

If  $x$  ranges over the interval  $0 \leq x \leq L$ , the substitution  $x' = \pi x/L$  allows the use of this definition also. The inverse transform is written

$$\bar{F}(x) = \frac{1}{\pi} f_c(0) + \frac{2}{\pi} \sum_{n=1}^{\infty} f_c(n) \cos nx \quad (0 < x < \pi) \quad (19.1.2)$$

where  $\bar{F}(x) = [F(x+0) + F(x-0)]/2$ . We observe that  $\bar{F}(x) = F(x)$  at points of continuity. The formula

$$\begin{aligned} f_c^{(2)}(n) &= \int_0^\pi F''(x) \cos nx \, dx \\ &= -n^2 f_c(n) - F'(0) + (-1)^n F'(\pi) \end{aligned} \quad (19.1.3)$$

makes the finite Fourier cosine transform useful in certain boundary value problems.

Analogously, the *finite Fourier sine transform* of  $F(x)$  is

$$f_s(n) = \int_0^\pi F(x) \sin nx \, dx \quad (n = 1, 2, 3, \dots) \tag{19.1.4}$$

and

$$\bar{F}(x) = \frac{2}{\pi} \sum_{n=1}^\infty f_s(n) \sin nx \quad (0 < x < \pi) \tag{19.1.5}$$

Corresponding to Equation (19.1.6), we have

$$\begin{aligned} f_s^{(2)}(n) &= \int_0^\pi F''(x) \sin nx \, dx \\ &= -n^2 f_s(n) - nF(0) - n(-1)^n F(\pi) \end{aligned} \tag{19.1.6}$$

### Fourier Transforms

If  $F(x)$  is defined for  $x \geq 0$  and is piecewise continuous over any finite interval, and if

$$\int_0^\infty F(x) \, dx$$

is absolutely convergent, then

$$f_c(\alpha) = \sqrt{\frac{2}{\pi}} \int_0^\infty F(x) \cos(\alpha x) \, dx \tag{19.1.7}$$

is the *Fourier cosine transform* of  $F(x)$ . Furthermore,

$$\bar{F}(x) = \sqrt{\frac{2}{\pi}} \int_0^\infty f_c(\alpha) \cos(\alpha x) \, d\alpha \tag{19.1.8}$$

If  $\lim_{x \rightarrow \infty} d^n F/dx^n = 0$ , an important property of the Fourier cosine transform,

$$\begin{aligned} f_c^{(2r)}(\alpha) &= \sqrt{\frac{2}{\pi}} \int_0^\infty \left( \frac{d^{2r} F}{dx^{2r}} \right) \cos(\alpha x) \, dx \\ &= -\sqrt{\frac{2}{\pi}} \sum_{n=0}^{r-1} (-1)^n a_{2r-2n-1} \alpha^{2n} + (-1)^r \alpha^{2r} f_c(\alpha) \end{aligned} \tag{19.1.9}$$

where  $\lim_{x \rightarrow 0} d^r F/dx^r = a_r$ , makes it useful in the solution of many problems.

Under the same conditions,

$$f_s(\alpha) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} F(x) \sin(\alpha x) dx \quad (19.1.10)$$

defines the *Fourier sine transform* of  $F(x)$ , and

$$\bar{F}(x) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f_s(\alpha) \sin(\alpha x) d\alpha \quad (19.1.11)$$

Corresponding to Equation (19.1.9) we have

$$\begin{aligned} f_s^{(2r)}(\alpha) &= \sqrt{\frac{2}{\pi}} \int_0^{\infty} \frac{d^{2r} F}{dx^{2r}} \sin(\alpha x) dx \\ &= -\sqrt{\frac{2}{\pi}} \sum_{n=1}^r (-1)^n \alpha^{2n-1} a_{2r-2n} + (-1)^{r-1} \alpha^{2r} f_s(\alpha) \end{aligned} \quad (19.1.12)$$

Similarly, if  $F(x)$  is defined for  $-\infty < x < \infty$ , and if  $\int_{-\infty}^{\infty} F(x) dx$  is absolutely convergent, then

$$f(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} F(\alpha) e^{i\alpha x} d\alpha \quad (19.1.13)$$

is the *Fourier transform* of  $F(x)$ , and

$$\bar{F}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} f(\alpha) e^{-i\alpha x} d\alpha \quad (19.1.14)$$

Also, if

$$\lim_{|x| \rightarrow \infty} \left| \frac{d^n F}{dx^n} \right| = 0 \quad (n = 1, 2, \dots, r-1)$$

then

$$f^{(r)}(\alpha) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} F^{(r)}(x) e^{i\alpha x} dx = (-i\alpha)^r f(\alpha) \quad (19.1.15)$$

### Finite Sine Transforms

$f_s(n)$	$F(x)$
1. $f_s(n) = \int_0^\pi F(x) \sin nx \, dx \quad (n = 1, 2, \dots)$	$F(x)$
2. $(-1)^{n+1} f_s(n)$	$F(\pi - x)$
3. $\frac{1}{n}$	$\frac{\pi - x}{\pi}$
4. $\frac{(-1)^{n+1}}{n}$	$\frac{x}{\pi}$
5. $\frac{1 - (-1)^n}{n}$	1
6. $\frac{2}{n^2} \sin \frac{n\pi}{2}$	$\begin{cases} x & \text{when } 0 < x < \pi/2 \\ \pi - x & \text{when } \pi/2 < x < \pi \end{cases}$
7. $\frac{(-1)^{n+1}}{n^3}$	$\frac{x(\pi^2 - x^2)}{6\pi}$
8. $\frac{1 - (-1)^n}{n^3}$	$\frac{x(\pi - x)}{2}$
9. $\frac{\pi^2 (-1)^{n-1}}{n} - \frac{2[1 - (-1)^n]}{n^3}$	$x^2$
10. $\pi(-1)^n \left( \frac{6}{n^3} - \frac{\pi^2}{n} \right)$	$x^3$
11. $\frac{n}{n^2 + c^2} [1 - (-1)^n e^{c\pi}]$	$e^{cx}$
12. $\frac{n}{n^2 + c^2}$	$\frac{\sinh c(\pi - x)}{\sinh c\pi}$
13. $\frac{n}{n^2 - k^2} \quad (k \neq 0, 1, 2, \dots)$	$\frac{\sinh k(\pi - x)}{\sinh k\pi}$

15. $\frac{n}{n^2 - k^2} [1 - (-1)^n \cos k\pi] \quad (k \neq 1, 2, \dots)$	$\cos kx$
16. $\begin{cases} \frac{n}{n^2 - m^2} [1 - (-1)^{n+m}] & \text{when } n \neq m = 1, 2, \dots \\ 0 & \text{when } n = m \end{cases}$	$\cos mx$
17. $\frac{n}{(n^2 - k^2)^2} \quad (k \neq 0, 1, 2, \dots)$	$\frac{\pi \sin kx}{2k \sin^2 kx} - \frac{x \cos k(\pi - x)}{2k \sin k\pi}$
18. $\frac{b^n}{n} \quad ( b  \leq 1)$	$\frac{2}{\pi} \arctan \frac{b \sin x}{1 - b \cos x}$
19. $\frac{1 - (-1)^n}{n} b^n \quad ( b  \leq 1)$	$\frac{2}{\pi} \arctan \frac{2b \sin x}{1 - b^2}$

### Finite Cosine Transforms

$f_c(n)$	$F(x)$
1. $f_c(n) = \int_0^\pi F(x) \cos nx \, dx \quad (n = 0, 1, 2, \dots)$	$F(x)$
2. $(-1)^n f_c(n)$	$F(\pi - x)$
3. 0 when $n = 1, 2, \dots$ ; $f_c(0) = \pi$	1
4. $\frac{2}{n} \sin \frac{n\pi}{2}$ ; $f_c(0) = 0$	$\begin{cases} 1 & \text{when } 0 < x < \pi/2 \\ -1 & \text{when } \pi/2 < x < \pi \end{cases}$
5. $-\frac{1 - (-1)^n}{n^2}$ ; $f_c(0) = \frac{\pi^2}{2}$	$x$
6. $\frac{(-1)^n}{n^2}$ ; $f_c(0) = \frac{\pi^2}{6}$	$\frac{x^2}{2\pi}$
7. $\frac{1}{n^2}$ ; $f_c(0) = 0$	$\frac{(\pi - x)^2}{2\pi} - \frac{\pi}{6}$
8. $3\pi^2 \frac{(-1)^n}{n^2} - 6 \frac{1 - (-1)^n}{n^4}$ ; $f_c(0) = \frac{\pi^4}{4}$	$x^3$
9. $\frac{(-1)^n e^c \pi - 1}{n^2 + c^2}$	$\frac{1}{c} e^{cx}$
10. $\frac{1}{n^2 + e^2}$	$\frac{\cosh c(\pi - x)}{c \sinh c\pi}$
11. $\frac{k}{n^2 - k^2} [(-1)^n \cos \pi k - 1] \quad (k \neq 0, 1, 2, \dots)$	$\sin kx$
12. $\frac{(-1)^{n+m} - 1}{n^2 - m^2}$ ; $f_c(m) = 0 \quad (m = 1, 2, \dots)$	$\frac{1}{m} \sin mx$
13. $\frac{1}{n^2 - k^2} \quad (k \neq 0, 1, 2, \dots)$	$-\frac{\cos k(\pi - x)}{k \sin k\pi}$
14. 0 when $n = 1, 2, \dots$ ; $f_c(m) = \frac{\pi}{2} \quad (m = 1, 2, \dots)$	$\cos mx$

### Fourier Sine Transforms

$F(x)$	$f_s(\alpha)$
1. $\begin{cases} 1 & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\sqrt{\frac{2}{\pi}} \left[ \frac{1 - \cos \alpha}{\alpha} \right]$
2. $x^{p-1} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(p)}{\alpha^p} \sin \frac{p\pi}{2}$
3. $\begin{cases} \sin x & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\frac{1}{\sqrt{2\pi}} \left[ \frac{\sin[a(1 - \alpha)]}{1 - \alpha} - \frac{\sin[a(1 + \alpha)]}{1 + \alpha} \right]$
4. $e^{-x}$	$\sqrt{\frac{2}{\pi}} \left[ \frac{\alpha}{1 + \alpha^2} \right]$
5. $x e^{-x^2/2}$	$\alpha e^{-\alpha^2/2}$

$F(x)$	$f_s(\alpha)$
6. $\cos \frac{x^2}{2}$	$\sqrt{2} \left[ \sin \frac{\alpha^2}{2} C\left(\frac{\alpha^2}{2}\right) - \cos \frac{\alpha^2}{2} S\left(\frac{\alpha^2}{2}\right) \right]^*$
7. $\sin \frac{x^2}{2}$	$\sqrt{2} \left[ \cos \frac{\alpha^2}{2} C\left(\frac{\alpha^2}{2}\right) + \sin \frac{\alpha^2}{2} S\left(\frac{\alpha^2}{2}\right) \right]^*$

\*  $C(y)$  and  $S(y)$  are the Fresnel integrals

$$C(y) = \frac{1}{\sqrt{2\pi}} \int_0^y \frac{1}{\sqrt{t}} \cos t \, dt$$

$$S(y) = \frac{1}{\sqrt{2\pi}} \int_0^y \frac{1}{\sqrt{t}} \sin t \, dt$$

### Fourier Cosine Transforms

$F(x)$	$f_c(\alpha)$
1. $\begin{cases} 1 & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\sqrt{\frac{2}{\pi}} \frac{\sin a\alpha}{\alpha}$
2. $x^{p-1} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(p)}{\alpha^p} \cos \frac{p\pi}{2}$
3. $\begin{cases} \cos x & (0 < x < a) \\ 0 & (x > a) \end{cases}$	$\frac{1}{\sqrt{2\pi}} \left[ \frac{\sin[a(1-\alpha)]}{1-\alpha} + \frac{\sin[a(1+\alpha)]}{1+\alpha} \right]$
4. $e^{-x}$	$\sqrt{\frac{2}{\pi}} \left( \frac{1}{1+\alpha^2} \right)$
5. $e^{-x^2/2}$	$e^{-\alpha^2/2}$
6. $\cos \frac{x^2}{2}$	$\cos \left( \frac{\alpha^2}{2} - \frac{\pi}{4} \right)$
7. $\sin \frac{x^2}{2}$	$\cos \left( \frac{\alpha^2}{2} - \frac{\pi}{4} \right)$

**Fourier Transforms**

$F(x)$	$f(\alpha)$
1. $\frac{\sin ax}{x}$	$\begin{cases} \sqrt{\frac{\pi}{2}} &  \alpha  < a \\ 0 &  \alpha  > a \end{cases}$
2. $\begin{cases} e^{iwx} & (p < x < q) \\ 0 & (x < p, x > q) \end{cases}$	$\frac{i}{\sqrt{2\pi}} \frac{e^{ip(w+\alpha)} - e^{iq(w+\alpha)}}{(w+\alpha)}$
3. $\begin{cases} e^{-cx+iwx} & (x > 0) \\ 0 & (x < 0) \end{cases} \quad (c > 0)$	$\frac{i}{\sqrt{2\pi}(w+\alpha+ic)}$
4. $e^{-px^2} \quad R(p) > 0$	$\frac{1}{\sqrt{2p}} e^{-\alpha^2/4p}$
5. $\cos px^2$	$\frac{1}{\sqrt{2p}} \cos \left[ \frac{\alpha^2}{4p} - \frac{\pi}{4} \right]$
6. $\sin px^2$	$\frac{1}{\sqrt{2p}} \cos \left[ \frac{\alpha^2}{4p} + \frac{\pi}{4} \right]$
7. $ x ^{-p} \quad (0 < p < 1)$	$\sqrt{\frac{2}{\pi}} \frac{\Gamma(1-p) \sin \frac{p\pi}{2}}{ \alpha ^{(1-p)}}$
8. $\frac{e^{-a x }}{\sqrt{ x }}$	$\frac{\sqrt{\sqrt{(a^2 + \alpha^2)} + a}}{\sqrt{a^2 + \alpha^2}}$
9. $\frac{\cosh ax}{\cosh \pi x} \quad (-\pi < a < \pi)$	$\sqrt{\frac{2}{\pi}} \frac{\cos \frac{a}{2} \cosh \frac{\alpha}{2}}{\cosh \alpha + \cos a}$
10. $\frac{\sinh ax}{\sinh \pi x} \quad (-\pi < a < \pi)$	$\frac{1}{\sqrt{2\pi}} \frac{\sin a}{\cosh \alpha + \cos a}$
11. $\begin{cases} \frac{1}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0(\alpha\alpha)$
12. $\frac{\sin \left[ b\sqrt{a^2 + x^2} \right]}{\sqrt{a^2 + x^2}}$	$\begin{cases} 0 & ( \alpha  > b) \\ \sqrt{\frac{\pi}{2}} J_0 \left( \sqrt{b^2 - \alpha^2} \right) & ( \alpha  < b) \end{cases}$
13. $\begin{cases} P_n(x) & ( x  < 1) \\ 0 & ( x  > 1) \end{cases}$	$\frac{i^n}{\sqrt{\alpha}} J_{n+1/2}(\alpha)$
14. $\begin{cases} \frac{\cos \left[ b\sqrt{a^2 - x^2} \right]}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0 \left( a\sqrt{a^2 + b^2} \right)$
15. $\begin{cases} \frac{\cosh \left[ b\sqrt{a^2 - x^2} \right]}{\sqrt{a^2 - x^2}} & ( x  < a) \\ 0 & ( x  > a) \end{cases}$	$\sqrt{\frac{\pi}{2}} J_0 \left( a\sqrt{a^2 - b^2} \right)$

The following functions appear among the entries of the tables on transforms.

Function	Definition	Name
$Ei(x)$	$\int_{-\infty}^x \frac{e^v}{v} dv$ ; or sometimes defined as $-Ei(-x) = \int_x^{\infty} \frac{e^{-v}}{v} dv$	Exponential integral function
$Si(x)$	$\int_0^x \frac{\sin v}{v} dv$	Sine integral function
$Ci(x)$	$\int_{\infty}^x \frac{\cos v}{v} dv$ ; or sometimes defined as negative of this integral	Cosine integral function
$erf(x)$	$\frac{2}{\sqrt{\pi}} \int_0^x e^{-v^2} dv$	Error function
$erfc(x)$	$1 - erf(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-v^2} dv$	Complementary function to error function
$L_n(x)$	$\frac{e^x}{n!} \frac{d^n}{dx^n} (x^n e^{-x})$ , $n = 0, 1, \dots$	Laguerre polynomial of degree $n$

## Bessel Functions

### Bessel Functions of the First Kind, $J_n(x)$ (Also Called Simply *Bessel Functions*) (Figure 19.1.13)

Domain:  $[x > 0]$

Recurrence relation:

$$J_{n+1}(x) = \frac{2n}{x} J_n(x) - J_{n-1}(x), \quad n = 0, 1, 2, \dots$$

Symmetry:  $J_{-n}(x) = (-1)^n J_n(x)$

# Table of Differential Equations

Equation	Solution
1. $y' = \frac{dy}{dx} = f(x)$	$y = \int f(x) dx + c$
2. $y' + p(x)y = q(x)$	$y = \exp[-\int p(x) dx] \{c + \int \exp[\int p(x) dx] q(x) dx\}$
3. $y' + p(x)y = q(x)y^\alpha$ $\alpha \neq 0, \alpha \neq 1$	Set $z = y^{1-\alpha} \rightarrow z' + (1-\alpha)p(x)z = (1-\alpha)q(x)$ and use 2
4. $y' = f(x)g(y)$	Integrate $\frac{dy}{g(y)} = f(x) dx$ (separable)
5. $\frac{dy}{dx} = f(x/y)$	Set $y = xu \rightarrow u + x \frac{du}{dx} = f(u)$  $\int \frac{1}{f(u)-u} du = \ln x  + c$ Set $x = X + \alpha, y = Y + \beta$
6. $y' = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$	Choose $\begin{cases} a_1\alpha + b_1\beta = -c_2 \\ a_2\alpha + b_2\beta = -c_1 \end{cases} \rightarrow Y' = f\left(\frac{a_1X + b_1Y}{a_2X + b_2Y}\right)$ If $a_1b_2 - a_2b_1 \neq 0$ , set $Y = Xu \rightarrow$ separable form $u + Xu' = f\left(\frac{a_1 + b_1u}{a_2 + b_2u}\right)$ If $a_1b_2 - a_2b_1 = 0$ , set $u = a_1x + b_1y \rightarrow$ $\frac{du}{dx} = a_1 + b_1f\left(\frac{u + c_1}{ku + c_2}\right)$ since $a_2x + b_2y = k(a_1x + b_1y)$ $y = c_1 \cos ax + c_2 \sin ax$ $y = c_1 e^{ax} + c_2 e^{-ax}$
7. $y'' + a^2y = 0$	$y = c_1 \cos ax + c_2 \sin ax$
8. $y'' - a^2y = 0$	$y = c_1 e^{ax} + c_2 e^{-ax}$
9. $y'' + ay' + by = 0$	Set $y = e^{-(a/2)x} u \rightarrow u'' + \left(b - \frac{a^2}{4}\right)u = 0$
10. $y'' + a(x)y' + b(x)y = 0$	Set $y = e^{-\int a(x) dx} \rightarrow u'' + \left[b(x) - \frac{a^2}{4} - \frac{a'}{2}\right]u = 0$
11. $x^2y'' + xy' + (x^2 - a^2)y = 0$ $a \geq 0$ (Bessel)	i. If $a$ is not an integer $y = c_1 J_a(x) + c_2 J_{-a}(x)$ (Bessel functions of first kind) ii. If $a$ is an integer (say, $n$ ) $y = c_1 J_n(x) + c_2 Y_n(x)$ ( $Y_n$ is Bessel function of second kind)
12. $(1 - x^2)y'' - 2xy' + a(a + 1)y = 0$ $a$ is real (Legendre)	$y(x) = c_1 p_a(x) + c_2 q_a(x)$ (Legendre functions)
13. $y' + ay^2 = bx^n$ (integrable Riccati) $a, b, n$ real	Set $u' = ayu \rightarrow u'' - abx^n u = 0$ and use 14
14. $y'' - ax^{-1}y' + b^2x^\mu y = 0$	$y = x^p [c_1 J_\nu(kx^q) + c_2 J_{-\nu}(kx^q)]$ where $p = (a + 1)/2, \nu = (a + 1)/(\mu + 2),$ $k = 2b/(\mu + 2), q = (\mu + 2)/2$
15. Item 13 shows that the Riccati equation is linearized by raising the order of the equation. The <i>Riccati chain</i> , which is linearizable by raising the order, is	$u' = uy, \quad u'' = u[y^1 + y^2], \quad u''' = u[y'' + 3yy' + y^3],$ $u^{(iv)} = u[y'''' + 4yy''' + 6y^2y'' + 3(y')^2 + y^4], \dots$ To use this consider the second-order equation $y'' + 3yy' + y^3 = f(x)$ . The Riccati transformation $u' = yu$ transforms this equation to the linear for $u''' = uf(x)$ !

## 19.2 Linear Algebra and Matrices

*George Cain*

### Basic Definitions

A *Matrix*  $\mathbf{A}$  is a rectangular array of numbers (real or complex)

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} & \cdots & a_{1m} \\ a_{21} & a_{22} & \cdots & a_{2m} \\ \vdots & & & \\ a_{n1} & a_{n2} & \cdots & a_{nm} \end{bmatrix}$$

The *size* of the matrix is said to be  $n \times m$ . The  $1 \times m$  matrices  $[a_{i1} \cdots a_{im}]$  are called rows of  $\mathbf{A}$ , and the  $n \times 1$  matrices

$$\begin{bmatrix} a_{1j} \\ a_{2j} \\ \vdots \\ a_{nj} \end{bmatrix}$$

are called *columns* of  $\mathbf{A}$ . An  $n \times m$  matrix thus consists of  $n$  rows and  $m$  columns;  $a_{ij}$  denotes the *element*, or *entry*, of  $\mathbf{A}$  in the  $i$ th row and  $j$ th column. A matrix consisting of just one row is called a *row vector*, whereas a matrix of just one column is called a *column vector*. The elements of a vector are frequently called *components* of the vector. When the size of the matrix is clear from the context, we sometimes write  $\mathbf{A} = (a_{ij})$ .

A matrix with the same number of rows as columns is a *square* matrix, and the number of rows and columns is the *order* of the matrix. The diagonal of an  $n \times n$  square matrix  $\mathbf{A}$  from  $a_{11}$  to  $a_{nn}$  is called the *main*, or *principal*, *diagonal*. The word *diagonal* with no modifier usually means the main diagonal. The *transpose* of a matrix  $\mathbf{A}$  is the matrix that results from interchanging the rows and columns of  $\mathbf{A}$ . It is usually denoted by  $\mathbf{A}^T$ . A matrix  $\mathbf{A}$  such that  $\mathbf{A} = \mathbf{A}^T$  is said to be *symmetric*. The *conjugate transpose* of  $\mathbf{A}$  is the matrix that results from replacing each element of  $\mathbf{A}^T$  by its complex conjugate, and is usually denoted by  $\mathbf{A}^H$ . A matrix such that  $\mathbf{A} = \mathbf{A}^H$  is said to be *Hermitian*.

A square matrix  $\mathbf{A} = (a_{ij})$  is *lower triangular* if  $a_{ij} = 0$  for  $j > i$  and is *upper triangular* if  $a_{ij} = 0$  for  $j < i$ . A matrix that is both upper and lower triangular is a *diagonal* matrix. The  $n \times n$  *identity matrix* is the  $n \times n$  diagonal matrix in which each element of the main diagonal is 1. It is traditionally denoted  $\mathbf{I}_n$ , or simply  $\mathbf{I}$  when the order is clear from the context.

## Algebra of Matrices

The sum and difference of two matrices  $\mathbf{A}$  and  $\mathbf{B}$  are defined whenever  $\mathbf{A}$  and  $\mathbf{B}$  have the same size. In that case  $\mathbf{C} = \mathbf{A} \pm \mathbf{B}$  is defined by  $\mathbf{C} = (c_{ij}) = (a_{ij} \pm b_{ij})$ . The product  $t\mathbf{A}$  of a scalar  $t$  (real or complex number) and a matrix  $\mathbf{A}$  is defined by  $t\mathbf{A} = (ta_{ij})$ . If  $\mathbf{A}$  is an  $n \times m$  matrix and  $\mathbf{B}$  is an  $m \times p$  matrix, the product  $\mathbf{C} = \mathbf{AB}$  is defined to be the  $n \times p$  matrix  $\mathbf{C} = (c_{ij})$  given by  $c_{ij} = \sum_{k=1}^m a_{ik}b_{kj}$ . Note that the product of an  $n \times m$  matrix and an  $m \times p$  matrix is an  $n \times p$  matrix, and the product is defined only when the number of columns of the first factor is the same as the number of rows of the second factor. Matrix multiplication is, in general, associative:  $\mathbf{A}(\mathbf{BC}) = (\mathbf{AB})\mathbf{C}$ . It also distributes over addition (and subtraction):

$$\mathbf{A}(\mathbf{B} + \mathbf{C}) = \mathbf{AB} + \mathbf{AC} \quad \text{and} \quad (\mathbf{A} + \mathbf{B})\mathbf{C} = \mathbf{AC} + \mathbf{BC}$$

It is, however, not in general true that  $\mathbf{AB} = \mathbf{BA}$ , even in case both products are defined. It is clear that  $(\mathbf{A} + \mathbf{B})^T = \mathbf{A}^T + \mathbf{B}^T$  and  $(\mathbf{A} + \mathbf{B})^H = \mathbf{A}^H + \mathbf{B}^H$ . It is also true, but not so obvious perhaps, that  $(\mathbf{AB})^T = \mathbf{B}^T\mathbf{A}^T$  and  $(\mathbf{AB})^H = \mathbf{B}^H\mathbf{A}^H$ .

The  $n \times n$  identity matrix  $\mathbf{I}$  has the property that  $\mathbf{IA} = \mathbf{AI} = \mathbf{A}$  for every  $n \times n$  matrix  $\mathbf{A}$ . If  $\mathbf{A}$  is square, and if there is a matrix  $\mathbf{B}$  such that  $\mathbf{AB} = \mathbf{BA} = \mathbf{I}$ , then  $\mathbf{B}$  is called the *inverse* of  $\mathbf{A}$  and is denoted  $\mathbf{A}^{-1}$ . This terminology and notation are justified by the fact that a matrix can have at most one inverse. A matrix having an inverse is said to be *invertible*, or *nonsingular*, while a matrix not having an inverse is said to be *noninvertible*, or *singular*. The product of two invertible matrices is invertible and, in fact,  $(\mathbf{AB})^{-1} = \mathbf{B}^{-1}\mathbf{A}^{-1}$ . The sum of two invertible matrices is, obviously, not necessarily invertible.

## Systems of Equations

The system of  $n$  linear equations in  $m$  unknowns

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \dots + a_{1m}x_m &= b_1 \\ a_{21}x_1 + a_{22}x_2 + a_{23}x_3 + \dots + a_{2m}x_m &= b_2 \\ &\vdots \\ a_{n1}x_1 + a_{n2}x_2 + a_{n3}x_3 + \dots + a_{nm}x_m &= b_n \end{aligned}$$

may be written  $\mathbf{Ax} = \mathbf{b}$ , where  $\mathbf{A} = (a_{ij})$ ,  $\mathbf{x} = [x_1 \ x_2 \ \dots \ x_m]^T$ , and  $\mathbf{b} = [b_1 \ b_2 \ \dots \ b_n]^T$ . Thus  $\mathbf{A}$  is an  $n \times m$  matrix, and  $\mathbf{x}$  and  $\mathbf{b}$  are column vectors of the appropriate sizes.

The matrix  $\mathbf{A}$  is called the *coefficient matrix* of the system. Let us first suppose the coefficient matrix is square; that is, there are an equal number of equations and unknowns. If  $\mathbf{A}$  is upper triangular, it is quite easy to find all solutions of the system. The  $i$ th equation will contain only the unknowns  $x_i, x_{i+1}, \dots, x_n$ , and one simply solves the equations in reverse order: the last equation is solved for  $x_n$ ; the result is substituted into the  $(n-1)$ st equation, which is then solved for  $x_{n-1}$ ; these values of  $x_n$  and  $x_{n-1}$  are substituted in the  $(n-2)$ th equation, which is solved for  $x_{n-2}$ , and so on. This procedure is known as *back substitution*.

The strategy for solving an arbitrary system is to find an upper-triangular system equivalent with it and solve this upper-triangular system using back substitution. First suppose the element  $a_{11} \neq 0$ . We may rearrange the equations to ensure this, unless, of course the first column of  $\mathbf{A}$  is all 0s. In this case proceed to the next step, to be described later. For each  $i \geq 2$  let  $m_{i1} = a_{i1}/a_{11}$ . Now replace the  $i$ th equation by the result of multiplying the first equation by  $m_{i1}$  and subtracting the new equation from the  $i$ th equation. Thus,

$$a_{i1}x_1 + a_{i2}x_2 + a_{i3}x_3 + \dots + a_{im}x_m = b_i$$

is replaced by

$$0 \cdot x_1 + (a_{i2} + m_{i1}a_{12})x_2 + (a_{i3} + m_{i1}a_{13})x_3 + \dots + (a_{im} + m_{i1}a_{1m})x_m = b_i + m_{i1}b_1$$

After this is done for all  $i = 2, 3, \dots, n$ , there results the equivalent system

$$\begin{aligned} a_{11}x_1 + a_{12}x_2 + a_{13}x_3 + \dots + a_{1n}x_n &= b_1 \\ 0 \cdot x_1 + a'_{22}x_2 + a'_{23}x_3 + \dots + a'_{2n}x_n &= b'_2 \\ 0 \cdot x_1 + a'_{32}x_2 + a'_{33}x_3 + \dots + a'_{3n}x_n &= b'_3 \\ &\vdots \\ 0 \cdot x_1 + a'_{n2}x_2 + a'_{n3}x_3 + \dots + a'_{nn}x_n &= b'_n \end{aligned}$$

in which all entries in the first column below  $a_{11}$  are 0. (Note that if all entries in the first column were 0 to begin with, then  $a_{11} = 0$  also.) This procedure is now repeated for the  $(n - 1) \times (n - 1)$  system

$$\begin{aligned} a'_{22}x_2 + a'_{23}x_3 + \dots + a'_{2n}x_n &= b'_2 \\ a'_{32}x_2 + a'_{33}x_3 + \dots + a'_{3n}x_n &= b'_3 \\ &\vdots \\ a'_{n2}x_2 + a'_{n3}x_3 + \dots + a'_{nn}x_n &= b'_n \end{aligned}$$

to obtain an equivalent system in which all entries of the coefficient matrix below  $a'_{22}$  are 0. Continuing, we obtain an upper-triangular system  $Ux = c$  equivalent with the original system. This procedure is known as *Gaussian elimination*. The number  $m_{ij}$  are known as the *multipliers*.

Essentially the same procedure may be used in case the coefficient matrix is not square. If the coefficient matrix is not square, we may make it square by appending either rows or columns of 0s as needed. Appending rows of 0s and appending 0s to make  $b$  have the appropriate size equivalent to appending equations  $0 = 0$  to the system. Clearly the new system has precisely the same solutions as the original system. Appending columns of 0s and adjusting the size of  $x$  appropriately yields a new system with additional unknowns, each appearing only with coefficient 0, thus not affecting the solutions of the original system. In either case we may assume the coefficient matrix is square, and apply the Gauss elimination procedure.

Suppose the matrix  $A$  is invertible. Then if there were no row interchanges in carrying out the above Gauss elimination procedure, we have the *LU factorization* of the matrix  $A$ :

$$A = LU$$

where  $U$  is the upper-triangular matrix produced by elimination and  $L$  is the lower-triangular matrix given by

$$L = \begin{bmatrix} 1 & 0 & \dots & \dots & 0 \\ m_{21} & 1 & 0 & \dots & 0 \\ \vdots & & \ddots & & \\ m_{n1} & m_{n2} & \dots & & 1 \end{bmatrix}$$

A permutation  $P_{ij}$  matrix is an  $n \times n$  matrix such that  $P_{ij} \mathbf{A}$  is the matrix that results from exchanging row  $i$  and  $j$  of the matrix  $\mathbf{A}$ . The matrix  $P_{ij}$  is the matrix that results from exchanging rows  $i$  and  $j$  of the identity matrix. A product  $\mathbf{P}$  of such matrices  $P_{ij}$  is called a *permutation matrix*. If row interchanges are required in the Gauss elimination procedure, then we have the factorization

$$\mathbf{PA} = \mathbf{LU}$$

where  $\mathbf{P}$  is the permutation matrix giving the required row exchanges.

## Vector Spaces

The collection of all column vectors with  $n$  real components is *Euclidean  $n$ -space*, and is denoted  $\mathbb{R}^n$ . The collection of column vectors with  $n$  complex components is denoted  $\mathbb{C}^n$ . We shall use *vector space* to mean either  $\mathbb{R}^n$  or  $\mathbb{C}^n$ . In discussing the space  $\mathbb{R}^n$ , the word *scalar* will mean a real number, and in discussing the space  $\mathbb{C}^n$ , it will mean a complex number. A subset  $S$  of a vector space is a *subspace* such that if  $\mathbf{u}$  and  $\mathbf{v}$  are vectors in  $S$ , and if  $c$  is any scalar, then  $\mathbf{u} + \mathbf{v}$  and  $c\mathbf{u}$  are in  $S$ . We shall sometimes use the word *space* to mean a subspace. If  $B = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_k\}$  is a collection of vectors in a vector space, then the set  $S$  consisting of all vectors  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m$  for all scalars  $c_1, c_2, \dots, c_m$  is a subspace, called the *span* of  $B$ . A collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  of vectors  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m$  is a *linear combination* of  $B$ . If  $S$  is a subspace and  $B = \{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  is a subset of  $S$  such that  $S$  is the span of  $B$ , then  $B$  is said to *span*  $S$ .

A collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  of  $n$ -vectors is *linearly dependent* if there exist scalars  $c_1, c_2, \dots, c_m$ , not all zero, such that  $c_1\mathbf{v}_1 + c_2\mathbf{v}_2 + \dots + c_m\mathbf{v}_m = \mathbf{0}$ . A collection of vectors that is not linearly dependent is said to be *linearly independent*. The modifier *linearly* is frequently omitted, and we speak simply of dependent and independent collections. A linearly independent collection of vectors in a space  $S$  that spans  $S$  is a *basis* of  $S$ . Every basis of a space  $S$  contains the same number of vectors; this number is the *dimension* of  $S$ . The dimension of the space consisting of only the zero vector is 0. The collection  $B = \{\mathbf{e}_1, \mathbf{e}_2, \dots, \mathbf{e}_n\}$ , where  $\mathbf{e}_1 = [1, 0, 0, \dots, 0]^T$ ,  $\mathbf{e}_2 = [0, 1, 0, \dots, 0]^T$ , and so forth ( $\mathbf{e}_i$  has 1 as its  $i$ th component and zero for all other components) is a basis for the spaces  $\mathbb{R}^n$  and  $\mathbb{C}^n$ . This is the *standard basis* for these spaces. The dimension of these spaces is thus  $n$ . In a space  $S$  of dimension  $n$ , no collection of fewer than  $n$  vectors can span  $S$ , and no collection of more than  $n$  vectors in  $S$  can be independent.

## Rank and Nullity

The *column space* of an  $n \times m$  matrix  $\mathbf{A}$  is the subspace of  $\mathbb{R}^n$  or  $\mathbb{C}^n$  spanned by the columns of  $\mathbf{A}$ . The *row space* is the subspace of  $\mathbb{R}^m$  or  $\mathbb{C}^m$  spanned by the rows of  $\mathbf{A}$ . Note that for any vector  $\mathbf{x} = [x_1, x_2, \dots, x_m]^T$ ,

$$\mathbf{Ax} = x_1 \begin{bmatrix} a_{11} \\ a_{21} \\ \vdots \\ a_{n1} \end{bmatrix} + x_2 \begin{bmatrix} a_{12} \\ a_{22} \\ \vdots \\ a_{n2} \end{bmatrix} + \dots + x_m \begin{bmatrix} a_{1m} \\ a_{2m} \\ \vdots \\ a_{nm} \end{bmatrix}$$

so that the column space is the collection of all vectors,  $\mathbf{Ax}$ , and thus the system  $\mathbf{Ax} = \mathbf{b}$  has a solution if and only if  $\mathbf{b}$  is a member of the column space of  $\mathbf{A}$ .

The dimension of the column space is the *rank* of  $\mathbf{A}$ . The row space has the same dimension as the column space. The set of all solutions of the system  $\mathbf{Ax} = \mathbf{0}$  is a subspace called the *null space* of  $\mathbf{A}$ , and the dimension of this null space is the *nullity* of  $\mathbf{A}$ . A fundamental result in matrix theory is the fact that, for an  $n \times m$  matrix  $\mathbf{A}$ ,

$$\text{rank } \mathbf{A} + \text{nullity } \mathbf{A} = m$$

The difference of any two solutions of the linear system  $\mathbf{Ax} = \mathbf{b}$  is a member of the null space of  $\mathbf{A}$ . Thus this system has at most one solution if and only if the nullity of  $\mathbf{A}$  is zero. If the system is square (that is, if  $\mathbf{A}$  is  $n \times n$ ), then there will be a solution for every right-hand side  $\mathbf{b}$  if and only if the collection of columns of  $\mathbf{A}$  is linearly independent, which is the same as saying the rank of  $\mathbf{A}$  is  $n$ . In this case the nullity must be zero. Thus, for any  $\mathbf{b}$ , the square system  $\mathbf{Ax} = \mathbf{b}$  has exactly one solution if and only if  $\text{rank } \mathbf{A} = n$ . In other words the  $n \times n$  matrix  $\mathbf{A}$  is invertible if and only if  $\text{rank } \mathbf{A} = n$ .

### Orthogonality and Length

The *inner product* of two vectors  $\mathbf{x}$  and  $\mathbf{y}$  is the scalar  $\mathbf{x}^H\mathbf{y}$ . The *length*, or *norm*,  $\|\mathbf{x}\|$ , of the vector  $\mathbf{x}$  is given by  $\|\mathbf{x}\| = \sqrt{\mathbf{x}^H\mathbf{x}}$ . A *unit vector* is a vector of norm 1. Two vectors  $\mathbf{x}$  and  $\mathbf{y}$  are *orthogonal* if  $\mathbf{x}^H\mathbf{y} = 0$ . A collection of vectors  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  in a space  $S$  is said to be an *orthonormal* collection if  $\mathbf{v}_i^H \mathbf{v}_j = 0$  for  $i \neq j$  and  $\mathbf{v}_i^H \mathbf{v}_i = 1$ . An orthonormal collection is necessarily linearly independent. If  $S$  is a subspace (of  $\mathbb{R}^n$  or  $\mathbb{C}^n$ ) spanned by the orthonormal collection  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$ , then the *projection* of a vector  $\mathbf{x}$  onto  $S$  is the vector

$$\text{proj}(\mathbf{x}; S) = (\mathbf{x}^H \mathbf{v}_1) \mathbf{v}_1 + (\mathbf{x}^H \mathbf{v}_2) \mathbf{v}_2 + \dots + (\mathbf{x}^H \mathbf{v}_m) \mathbf{v}_m$$

The projection of  $\mathbf{x}$  onto  $S$  minimizes the function  $f(\mathbf{y}) = \|\mathbf{x} - \mathbf{y}\|^2$  for  $\mathbf{y} \in S$ . In other words the projection of  $\mathbf{x}$  onto  $S$  is the vector in  $S$  that is “closest” to  $\mathbf{x}$ .

If  $\mathbf{b}$  is a vector and  $\mathbf{A}$  is an  $n \times m$  matrix, then a vector  $\mathbf{x}$  minimizes  $\|\mathbf{b} - \mathbf{Ax}\|^2$  if and only if it is a solution of  $\mathbf{A}^H\mathbf{Ax} = \mathbf{A}^H\mathbf{b}$ . This system of equations is called the *system of normal equations* for the least-squares problem of minimizing  $\|\mathbf{b} - \mathbf{Ax}\|^2$ .

If  $\mathbf{A}$  is an  $n \times m$  matrix, and  $\text{rank } \mathbf{A} = k$ , then there is a  $n \times k$  matrix  $\mathbf{Q}$  whose columns form an orthonormal basis for the column space of  $\mathbf{A}$  and a  $k \times m$  upper-triangular matrix  $\mathbf{R}$  of rank  $k$  such that

$$\mathbf{A} = \mathbf{QR}$$

This is called the *QR factorization* of  $\mathbf{A}$ . It now follows that  $\mathbf{x}$  minimizes  $\|\mathbf{b} - \mathbf{Ax}\|^2$  if and only if it is a solution of the upper-triangular system  $\mathbf{Rx} = \mathbf{Q}^H\mathbf{b}$ .

If  $\{\mathbf{w}_1, \mathbf{w}_2, \dots, \mathbf{w}_m\}$  is a basis for a space  $S$ , the following procedure produces an orthonormal basis  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_m\}$  for  $S$ .

Set  $\mathbf{v}_1 = \mathbf{w}_1 / \|\mathbf{w}_1\|$ .

Let  $\tilde{\mathbf{v}}_2 = \mathbf{w}_2 - \text{proj}(\mathbf{w}_2; S_1)$ , where  $S_1$  is the span of  $\{\mathbf{v}_1\}$ ; set  $\mathbf{v}_2 = \tilde{\mathbf{v}}_2 / \|\tilde{\mathbf{v}}_2\|$ .

Next, let  $\tilde{\mathbf{v}}_3 = \mathbf{w}_3 - \text{proj}(\mathbf{w}_3; S_2)$ , where  $S_2$  is the span of  $\{\mathbf{v}_1, \mathbf{v}_2\}$ ; set  $\mathbf{v}_3 = \tilde{\mathbf{v}}_3 / \|\tilde{\mathbf{v}}_3\|$ .

And, so on:  $\tilde{\mathbf{v}}_i = \mathbf{w}_i - \text{proj}(\mathbf{w}_i; S_{i-1})$ , where  $S_{i-1}$  is the span of  $\{\mathbf{v}_1, \mathbf{v}_2, \dots, \mathbf{v}_{i-1}\}$ ; set  $\mathbf{v}_i = \tilde{\mathbf{v}}_i / \|\tilde{\mathbf{v}}_i\|$ . This is the *Gram-Schmidt procedure*.

If the collection of columns of a square matrix is an orthonormal collection, the matrix is called a *unitary matrix*. In case the matrix is a real matrix, it is usually called an *orthogonal matrix*. A unitary matrix  $\mathbf{U}$  is invertible, and  $\mathbf{U}^{-1} = \mathbf{U}^H$ . (In the real case an orthogonal matrix  $\mathbf{Q}$  is invertible, and  $\mathbf{Q}^{-1} = \mathbf{Q}^T$ .)

### Determinants

The *determinant* of a square matrix is defined inductively. First, suppose the determinant  $\det \mathbf{A}$  has been defined for all square matrices of order  $< n$ . Then

$$\det \mathbf{A} = a_{11} C_{11} + a_{12} C_{12} + \dots + a_{1n} C_{1n}$$

where the numbers  $C_{ij}$  are *cofactors* of the matrix  $\mathbf{A}$ :

$$C_{ij} = (-1)^{i+j} \det M_{ij}$$

where  $M_{ij}$  is the  $(n-1) \times (n-1)$  matrix obtained by deleting the  $i$ th row and  $j$ th column of  $\mathbf{A}$ . Now  $\det \mathbf{A}$  is defined to be the only entry of a matrix of order 1. Thus, for a matrix of order 2, we have

$$\det \begin{bmatrix} a & b \\ c & d \end{bmatrix} = ad - bc$$

There are many interesting but not obvious properties of determinants. It is true that

$$\det \mathbf{A} = a_{i1} C_{i1} + a_{i2} C_{i2} + \dots + a_{in} C_{in}$$

for any  $1 \leq i \leq n$ . It is also true that  $\det \mathbf{A} = \det \mathbf{A}^T$ , so that we have

$$\det \mathbf{A} = a_{1j} C_{1j} + a_{2j} C_{2j} + \dots + a_{nj} C_{nj}$$

for any  $1 \leq j \leq n$ .

If  $\mathbf{A}$  and  $\mathbf{B}$  are matrices of the same order, then  $\det \mathbf{AB} = (\det \mathbf{A})(\det \mathbf{B})$ , and the determinant of any identity matrix is 1. Perhaps the most important property of the determinant is the fact that a matrix is invertible if and only if its determinant is not zero.

## Eigenvalues and Eigenvectors

If  $\mathbf{A}$  is a square matrix, and  $\mathbf{A}\mathbf{v} = \lambda\mathbf{v}$  for a scalar  $\lambda$  and a nonzero  $\mathbf{v}$ , then  $\lambda$  is an *eigenvalue* of  $\mathbf{A}$  and  $\mathbf{v}$  is an *eigenvector* of  $\mathbf{A}$  that *corresponds* to  $\lambda$ . Any nonzero linear combination of eigenvectors corresponding to the same eigenvalue  $\lambda$  is also an eigenvector corresponding to  $\lambda$ . The collection of all eigenvectors corresponding to a given eigenvalue  $\lambda$  is thus a subspace, called an *eigenspace* of  $\mathbf{A}$ . A collection of eigenvectors corresponding to different eigenvalues is necessarily linear-independent. It follows that a matrix of order  $n$  can have at most  $n$  distinct eigenvectors. In fact, the eigenvalues of  $\mathbf{A}$  are the roots of the  $n$ th degree polynomial equation

$$\det(\mathbf{A} - \lambda\mathbf{I}) = 0$$

called the *characteristic equation* of  $\mathbf{A}$ . (Eigenvalues and eigenvectors are frequently called *characteristic values* and *characteristic vectors*.)

If the  $n$ th order matrix  $\mathbf{A}$  has an independent collection of  $n$  eigenvectors, then  $\mathbf{A}$  is said to have a *full set* of eigenvectors. In this case there is a set of eigenvectors of  $\mathbf{A}$  that is a basis for  $\mathbb{R}^n$  or, in the complex case,  $\mathbb{C}^n$ . In case there are  $n$  distinct eigenvalues of  $\mathbf{A}$ , then, of course,  $\mathbf{A}$  has a full set of eigenvectors. If there are fewer than  $n$  distinct eigenvalues, then  $\mathbf{A}$  may or may not have a full set of eigenvectors. If there is a full set of eigenvectors, then

$$\mathbf{D} = \mathbf{S}^{-1}\mathbf{A}\mathbf{S} \quad \text{or} \quad \mathbf{A} = \mathbf{S}\mathbf{D}\mathbf{S}^{-1}$$

where  $\mathbf{D}$  is a diagonal matrix with the eigenvalues of  $\mathbf{A}$  on the diagonal, and  $\mathbf{S}$  is a matrix whose columns are the full set of eigenvectors. If  $\mathbf{A}$  is symmetric, there are  $n$  real distinct eigenvalues of  $\mathbf{A}$  and the corresponding eigenvectors are orthogonal. There is thus an orthonormal collection of eigenvectors that span  $\mathbb{R}^n$ , and we have

$$\mathbf{A} = \mathbf{Q}\mathbf{D}\mathbf{Q}^T \quad \text{and} \quad \mathbf{D} = \mathbf{Q}^T\mathbf{A}\mathbf{Q}$$

where  $\mathbf{Q}$  is a real orthogonal matrix and  $\mathbf{D}$  is diagonal. For the complex case, if  $\mathbf{A}$  is Hermitian, we have

$$\mathbf{A} = \mathbf{U}\mathbf{D}\mathbf{U}^H \quad \text{and} \quad \mathbf{D} = \mathbf{U}^H\mathbf{A}\mathbf{U}$$

where  $\mathbf{U}$  is a unitary matrix and  $\mathbf{D}$  is a *real* diagonal matrix. (A Hermitian matrix also has  $n$  distinct real eigenvalues.)

## 19.3 Vector Algebra and Calculus

*George Cain*

### Basic Definitions

A vector is a directed line segment, with two vectors being equal if they have the same length and the same direction. More precisely, a *vector* is an equivalence class of directed line segments, where two directed segments are equivalent if they have the same length and the same direction. The *length* of a vector is the common length of its directed segments, and the *angle between* vectors is the angle between any of their segments. The length of a vector  $\mathbf{u}$  is denoted  $|\mathbf{u}|$ . There is defined a distinguished vector having zero length, which is usually denoted  $\mathbf{0}$ . It is frequently useful to visualize a directed segment as an arrow; we then speak of the nose and the tail of the segment. The *sum*  $\mathbf{u} + \mathbf{v}$  of two vectors  $\mathbf{u}$  and  $\mathbf{v}$  is defined by taking directed segments from  $\mathbf{u}$  and  $\mathbf{v}$  and placing the tail of the segment representing  $\mathbf{v}$  at the nose of the segment representing  $\mathbf{u}$  and defining  $\mathbf{u} + \mathbf{v}$  to be the vector determined by the segment from the tail of the  $\mathbf{u}$  representative to the nose of the  $\mathbf{v}$  representative. It is easy to see that  $\mathbf{u} + \mathbf{v}$  is well defined and that  $\mathbf{u} + \mathbf{v} = \mathbf{v} + \mathbf{u}$ . Subtraction is the inverse operation of addition. Thus the *difference*  $\mathbf{u} - \mathbf{v}$  of two vectors is defined to be the vector that when added to  $\mathbf{v}$  gives  $\mathbf{u}$ . In other words, if we take a segment from  $\mathbf{u}$  and a segment from  $\mathbf{v}$  and place their tails together, the difference is the segment from the nose of  $\mathbf{v}$  to the nose of  $\mathbf{u}$ . The zero vector behaves as one might expect;  $\mathbf{u} + \mathbf{0} = \mathbf{u}$ , and  $\mathbf{u} - \mathbf{u} = \mathbf{0}$ . Addition is associative:  $\mathbf{u} + (\mathbf{v} + \mathbf{w}) = (\mathbf{u} + \mathbf{v}) + \mathbf{w}$ .

To distinguish them from vectors, the real numbers are called *scalars*. The product  $t\mathbf{u}$  of a scalar  $t$  and a vector  $\mathbf{u}$  is defined to be the vector having length  $|t| |\mathbf{u}|$  and direction the same as  $\mathbf{u}$  if  $t > 0$ , the opposite direction if  $t < 0$ . If  $t = 0$ , then  $t\mathbf{u}$  is defined to be the zero vector. Note that  $t(\mathbf{u} + \mathbf{v}) = t\mathbf{u} + t\mathbf{v}$ , and  $(t + s)\mathbf{u} = t\mathbf{u} + s\mathbf{u}$ . From this it follows that  $\mathbf{u} - \mathbf{v} = \mathbf{u} + (-1)\mathbf{v}$ .

The *scalar product*  $\mathbf{u} \cdot \mathbf{v}$  of two vectors is  $|\mathbf{u}||\mathbf{v}| \cos \theta$ , where  $\theta$  is the angle between  $\mathbf{u}$  and  $\mathbf{v}$ . The scalar product is frequently called the *dot product*. The scalar product distributes over addition:

$$\mathbf{u} \cdot (\mathbf{v} + \mathbf{w}) = \mathbf{u} \cdot \mathbf{v} + \mathbf{u} \cdot \mathbf{w}$$

and it is clear that  $(t\mathbf{u}) \cdot \mathbf{v} = t(\mathbf{u} \cdot \mathbf{v})$ . The *vector product*  $\mathbf{u} \times \mathbf{v}$  of two vectors is defined to be the vector perpendicular to both  $\mathbf{u}$  and  $\mathbf{v}$  and having length  $|\mathbf{u}||\mathbf{v}| \sin \theta$ , where  $\theta$  is the angle between  $\mathbf{u}$  and  $\mathbf{v}$ . The direction of  $\mathbf{u} \times \mathbf{v}$  is the direction a right-hand threaded bolt advances if the vector  $\mathbf{u}$  is rotated to  $\mathbf{v}$ . The vector is frequently called the *cross product*. The vector product is both associative and distributive, but not commutative:  $\mathbf{u} \times \mathbf{v} = -\mathbf{v} \times \mathbf{u}$ .

## Coordinate Systems

Suppose we have a right-handed Cartesian coordinate system in space. For each vector,  $\mathbf{u}$ , we associate a point in space by placing the tail of a representative of  $\mathbf{u}$  at the origin and associating with  $\mathbf{u}$  the point at the nose of the segment. Conversely, associated with each point in space is the vector determined by the directed segment from the origin to that point. There is thus a one-to-one correspondence between the points in space and all vectors. The origin corresponds to the zero vector. The coordinates of the point associated with a vector  $\mathbf{u}$  are called *coordinates* of  $\mathbf{u}$ . One frequently refers to the vector  $\mathbf{u}$  and writes  $\mathbf{u} = (x, y, z)$ , which is, strictly speaking, incorrect, because the left side of this equation is a vector and the right side gives the coordinates of a point in space. What is meant is that  $(x, y, z)$  are the coordinates of the point associated with  $\mathbf{u}$  under the correspondence described. In terms of coordinates, for  $\mathbf{u} = (u_1, u_2, u_3)$  and  $\mathbf{v} = (v_1, v_2, v_3)$ , we have

$$\mathbf{u} + \mathbf{v} = (u_1 + v_1, u_2 + v_2, u_3 + v_3)$$

$$t\mathbf{u} = (tu_1, tu_2, tu_3)$$

$$\mathbf{u} \cdot \mathbf{v} = u_1v_1 + u_2v_2 + u_3v_3$$

$$\mathbf{u} \times \mathbf{v} = (u_2v_3 - v_2u_3, u_3v_1 - v_3u_1, u_1v_2 - v_1u_2)$$

The *coordinate vectors*  $\mathbf{i}$ ,  $\mathbf{j}$ , and  $\mathbf{k}$  are the unit vectors  $\mathbf{i} = (1, 0, 0)$ ,  $\mathbf{j} = (0, 1, 0)$ , and  $\mathbf{k} = (0, 0, 1)$ . Any vector  $\mathbf{u} = (u_1, u_2, u_3)$  is thus a linear combination of these coordinate vectors:  $\mathbf{u} = u_1\mathbf{i} + u_2\mathbf{j} + u_3\mathbf{k}$ . A convenient form for the vector product is the formal determinant

$$\mathbf{u} \times \mathbf{v} = \det \begin{bmatrix} \mathbf{i} & \mathbf{j} & \mathbf{k} \\ u_1 & u_2 & u_3 \\ v_1 & v_2 & v_2 \end{bmatrix}$$

## Vector Functions

A *vector function*  $\mathbf{F}$  of one variable is a rule that associates a vector  $\mathbf{F}(t)$  with each real number  $t$  in some set, called the *domain* of  $\mathbf{F}$ . The expression  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{a}$  means that for any  $\varepsilon > 0$ , there is a  $\delta > 0$  such that  $|\mathbf{F}(t) - \mathbf{a}| < \varepsilon$  whenever  $0 < |t - t_0| < \delta$ . If  $\mathbf{F}(t) = [x(t), y(t), z(t)]$  and  $\mathbf{a} = (a_1, a_2, a_3)$ , then  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{a}$  if and only if

$$\lim_{t \rightarrow t_0} x(t) = a_1$$

$$\lim_{t \rightarrow t_0} y(t) = a_2$$

$$\lim_{t \rightarrow t_0} z(t) = a_3$$

A vector function  $\mathbf{F}$  is *continuous* at  $t_0$  if  $\lim_{t \rightarrow t_0} \mathbf{F}(t) = \mathbf{F}(t_0)$ . The vector function  $\mathbf{F}$  is continuous at  $t_0$  if and only if each of the coordinates  $x(t)$ ,  $y(t)$ , and  $z(t)$  is continuous at  $t_0$ .

The function  $\mathbf{F}$  is *differentiable* at  $t_0$  if the limit

$$\lim_{h \rightarrow 0} \frac{1}{h} [\mathbf{F}(t+h) - \mathbf{F}(t)]$$

exists. This limit is called the *derivative* of  $\mathbf{F}$  at  $t_0$  and is usually written  $\mathbf{F}'(t_0)$ , or  $(d\mathbf{F}/dt)(t_0)$ . The vector function  $\mathbf{F}$  is differentiable at  $t_0$  if and only if each of its coordinate functions is differentiable at  $t_0$ . Moreover,  $(d\mathbf{F}/dt)(t_0) = [(dx/dt)(t_0), (dy/dt)(t_0), (dz/dt)(t_0)]$ . The usual rules for derivatives of real valued functions all hold for vector functions. Thus if  $\mathbf{F}$  and  $\mathbf{G}$  are vector functions and  $s$  is a scalar function, then

$$\begin{aligned} \frac{d}{dt}(\mathbf{F} + \mathbf{G}) &= \frac{d\mathbf{F}}{dt} + \frac{d\mathbf{G}}{dt} \\ \frac{d}{dt}(s\mathbf{F}) &= s \frac{d\mathbf{F}}{dt} + \frac{ds}{dt} \mathbf{F} \\ \frac{d}{dt}(\mathbf{F} \cdot \mathbf{G}) &= \mathbf{F} \cdot \frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt} \cdot \mathbf{G} \\ \frac{d}{dt}(\mathbf{F} \times \mathbf{G}) &= \mathbf{F} \times \frac{d\mathbf{G}}{dt} + \frac{d\mathbf{F}}{dt} \times \mathbf{G} \end{aligned}$$

If  $\mathbf{R}$  is a vector function defined for  $t$  in some interval, then, as  $t$  varies, with the tail of  $\mathbf{R}$  at the origin, the nose traces out some object  $C$  in space. For nice functions  $\mathbf{R}$ , the object  $C$  is a *curve*. If  $\mathbf{R}(t) = [x(t), y(t), z(t)]$ , then the equations

$$\begin{aligned} x &= x(t) \\ y &= y(t) \\ z &= z(t) \end{aligned}$$

are called *parametric equations* of  $C$ . At points where  $\mathbf{R}$  is differentiable, the derivative  $d\mathbf{R}/dt$  is a vector *tangent* to the curve. The unit vector  $\mathbf{T} = (d\mathbf{R}/dt)/|d\mathbf{R}/dt|$  is called the *unit tangent vector*. If  $\mathbf{R}$  is differentiable and if the length of the arc of curve described by  $\mathbf{R}$  between  $\mathbf{R}(a)$  and  $\mathbf{R}(t)$  is given by  $s(t)$ , then

$$\frac{ds}{dt} = \left| \frac{d\mathbf{R}}{dt} \right|$$

Thus the length  $L$  of the arc from  $\mathbf{R}(t_0)$  to  $\mathbf{R}(t_1)$  is

$$L = \int_{t_0}^{t_1} \frac{ds}{dt} dt = \int_{t_0}^{t_1} \left| \frac{d\mathbf{R}}{dt} \right| dt$$

The vector  $d\mathbf{T}/ds = (d\mathbf{T}/dt)/(ds/dt)$  is perpendicular to the unit tangent  $\mathbf{T}$ , and the number  $\kappa = |d\mathbf{T}/ds|$  is the *curvature* of  $C$ . The unit vector  $\mathbf{N} = (1/\kappa)(d\mathbf{T}/ds)$  is the *principal normal*. The vector  $\mathbf{B} = \mathbf{T} \times \mathbf{N}$  is the *binormal*, and  $d\mathbf{B}/ds = -\tau\mathbf{N}$ . The number  $\tau$  is the *torsion*. Note that  $C$  is a plane curve if and only if  $\tau$  is zero for all  $t$ .

A *vector function*  $\mathbf{F}$  of two variables is a rule that assigns a vector  $\mathbf{F}(s, t)$  in some subset of the plane, called the *domain* of  $\mathbf{F}$ . If  $\mathbf{R}(s, t)$  is defined for all  $(s, t)$  in some region  $D$  of the plane, then as the point  $(s, t)$  varies over  $D$ , with its tail at the origin, the nose of  $\mathbf{R}(s, t)$  traces out an object in space. For a nice function  $\mathbf{R}$ , this object is a *surface*,  $S$ . The partial derivatives  $(\partial\mathbf{R}/\partial s)(s, t)$  and  $(\partial\mathbf{R}/\partial t)(s, t)$  are tangent to the surface at  $\mathbf{R}(s, t)$ , and the vector  $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$  is thus *normal* to the surface. Of course,  $(\partial\mathbf{R}/\partial t) \times (\partial\mathbf{R}/\partial s) = -(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$  is also normal to the surface and points in the direction opposite that of  $(\partial\mathbf{R}/\partial s) \times (\partial\mathbf{R}/\partial t)$ . By electing one of these normal, we are choosing an *orientation* of the surface.

A surface can be oriented only if it has two sides, and the process of orientation consists of choosing which side is “positive” and which is “negative.”

## Gradient, Curl, and Divergence

If  $f(x, y, z)$  is a scalar field defined in some region  $D$ , the *gradient* of  $f$  is the vector function

$$\text{grad } f = \frac{\partial f}{\partial x} \mathbf{i} + \frac{\partial f}{\partial y} \mathbf{j} + \frac{\partial f}{\partial z} \mathbf{k}$$

If  $\mathbf{F}(x, y, z) = F_1(x, y, z)\mathbf{i} + F_2(x, y, z)\mathbf{j} + F_3(x, y, z)\mathbf{k}$  is a vector field defined in some region  $D$ , then the *divergence* of  $\mathbf{F}$  is the scalar function

$$\text{div } \mathbf{F} = \frac{\partial F_1}{\partial x} + \frac{\partial F_2}{\partial y} + \frac{\partial F_3}{\partial z}$$

The curl is the vector function

$$\text{curl } \mathbf{F} = \left( \frac{\partial F_3}{\partial y} - \frac{\partial F_2}{\partial z} \right) \mathbf{i} + \left( \frac{\partial F_1}{\partial z} - \frac{\partial F_3}{\partial x} \right) \mathbf{j} + \left( \frac{\partial F_2}{\partial x} - \frac{\partial F_1}{\partial y} \right) \mathbf{k}$$

In terms of the vector operator  $del$ ,  $\nabla = \mathbf{i}(\partial/\partial x) + \mathbf{j}(\partial/\partial y) + \mathbf{k}(\partial/\partial z)$ , we can write

$$\text{grad } f = \nabla f$$

$$\text{div } \mathbf{F} = \nabla \cdot \mathbf{F}$$

$$\text{curl } \mathbf{F} = \nabla \times \mathbf{F}$$

The *Laplacian operator* is  $\text{div}(\text{grad}) = \nabla \cdot \nabla = \nabla^2 = (\partial^2/\partial x^2) + (\partial^2/\partial y^2) + (\partial^2/\partial z^2)$ .

## Integration

Suppose  $C$  is a curve from the point  $(x_0, y_0, z_0)$  to the point  $(x_1, y_1, z_1)$  and is described by the vector function  $\mathbf{R}(t)$  for  $t_0 \leq t \leq t_1$ . If  $f$  is a scalar function (sometimes called a *scalar field*) defined on  $C$ , then the integral of  $f$  over  $C$  is

$$\int_C f(x, y, z) \, ds = \int_{t_0}^{t_1} f[\mathbf{R}(t)] \left| \frac{d\mathbf{R}}{dt} \right| dt$$

If  $\mathbf{F}$  is a vector function (sometimes called a *vector field*) defined on  $C$ , then the integral of  $\mathbf{F}$  over  $C$  is

$$\int_C \mathbf{F}(x, y, z) \cdot d\mathbf{R} = \int_{t_0}^{t_1} \mathbf{F}[\mathbf{R}(t)] \frac{d\mathbf{R}}{dt} dt$$

These integrals are called *line integrals*.

In case there is a scalar function  $f$  such that  $\mathbf{F} = \text{grad } f$ , then the line integral

$$\int_C \mathbf{F}(x, y, z) \cdot d\mathbf{R} = f[\mathbf{R}(t_1)] - f[\mathbf{R}(t_0)]$$

The value of the integral thus depends only on the end points of the curve  $C$  and not on the curve  $C$  itself. The integral is said to be *path-independent*. The function  $f$  is called a *potential function* for the vector field  $\mathbf{F}$ , and  $\mathbf{F}$  is said to be a *conservative field*. A vector field  $\mathbf{F}$  with domain  $D$  is conservative if and only if the integral of  $\mathbf{F}$  around every closed curve in  $D$  is zero. If the domain  $D$  is simply connected (that is, every closed curve in  $D$  can be continuously deformed in  $D$  to a point), then  $\mathbf{F}$  is conservative if and only if  $\text{curl } \mathbf{F} = 0$  in  $D$ .

Suppose  $S$  is a surface described by  $\mathbf{R}(s, t)$  for  $(s, t)$  in a region  $D$  of the plane. If  $f$  is a scalar function defined on  $D$ , then the integral of  $f$  over  $S$  is given by

$$\iint_S f(x, y, z) \, dS = \iint_D f[\mathbf{R}(s, t)] \left| \frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t} \right| \, ds \, dt$$

If  $\mathbf{F}$  is a vector function defined on  $S$ , and if an orientation for  $S$  is chosen, then the integral  $\mathbf{F}$  over  $S$ , sometimes called the flux of  $\mathbf{F}$  through  $S$ , is

$$\iint_S \mathbf{F}(x, y, z) \cdot d\mathbf{S} = \iint_D \mathbf{F}[\mathbf{R}(s, t)] \left| \frac{\partial \mathbf{R}}{\partial s} \times \frac{\partial \mathbf{R}}{\partial t} \right| \, ds \, dt$$

### Integral Theorems

Suppose  $\mathbf{F}$  is a vector field with a closed domain  $D$  bounded by the surface  $S$  oriented so that the normal points out from  $D$ . Then the *divergence theorem* states that

$$\iiint_D \text{div } \mathbf{F} \, dV = \iint_S \mathbf{F} \cdot d\mathbf{S}$$

If  $S$  is an orientable surface bounded by a closed curve  $C$ , the orientation of the closed curve  $C$  is chosen to be consistent with the orientation of the surface  $S$ . Then we have *Stoke's theorem*:

$$\iint_S (\text{curl } \mathbf{F}) \cdot d\mathbf{S} = \oint_C \mathbf{F} \cdot d\mathbf{s}$$

## 19.4 Difference Equations

*William F. Ames*

Difference equations are equations involving *discrete variables*. They appear as natural descriptions of natural phenomena and in the study of discretization methods for differential equations, which have continuous variables.

Let  $y_n = y(nh)$ , where  $n$  is an integer and  $h$  is a real number. (One can think of measurements taken at equal intervals,  $h, 2h, 3h, \dots$ , and  $y_n$  describes these). A typical equation is that describing the famous Fibonacci sequence —  $y_{n+2} - y_{n+1} - y_n = 0$ . Another example is the equation  $y_{n+2} - 2zy_{n+1} + y_n = 0$ ,  $z \in \mathbb{C}$ , which describes the Chebyshev polynomials.

### First-Order Equations

The general first-order equation  $y_{n+1} = f(y_n)$ ,  $y_0 = y(0)$  is easily solved, for as many terms as are needed, by *iteration*. Then  $y_1 = f(y_0)$ ;  $y_2 = f(y_1), \dots$ . An example is the logistic equation  $y_{n+1} = ay_n(1 - y_n) = f(y_n)$ . The logistic equation has two fixed (critical or equilibrium) points where  $y_{n+1} = y_n$ . They are 0 and  $\bar{y} = (a - 1)/a$ . This has physical meaning only for  $a > 1$ . For  $1 < a < 3$  the equilibrium  $\bar{y}$  is asymptotically stable, and for  $a > 3$  there are two points  $y_1$  and  $y_2$ , called a *cycle of period two*, in which  $y_2 = f(y_1)$  and  $y_1 = f(y_2)$ . This study leads into chaos, which is outside our interest. By iteration, with  $y_0 = 1/2$ , we have  $y_1 = (a/2)(1/2) = a/2^2$ ,  $y_2 = a(a/2^2)(1 - a/2^2) = (a^2/2^2)(1 - a/2^2), \dots$

With a constant, the equation  $y_{n+1} = ay_n$  is solved by making the assumption  $y_n = A\lambda^n$  and finding  $\lambda$  so that the equation holds. Thus  $A\lambda^{n+1} = aA\lambda^n$ , and hence  $\lambda = 0$  or  $\lambda = a$  and  $A$  is arbitrary. Discarding the trivial solution 0 we find  $y_n = Aa^{n+1}$  is the desired solution. By using a method called the *variation of constants*, the equation  $y_{n+1} - ay_n = g_n$  has the solution  $y_n = y_0a^n + \sum_{j=0}^{n-1} g_j a^{n-j-1}$ , with  $y_0$  arbitrary.

In various applications we find the first-order equation of *Riccati type*  $y_n y_{n-1} + ay_n + by_{n-1} + c = 0$  where  $a, b$ , and  $c$  are real constants. This equation can be transformed to a linear second-order equation by setting  $y_n = z_n/z_{n-1} - a$  to obtain  $z_{n+1} + (b + a)z_n + (c - ab)z_{n-1} = 0$ , which is solvable as described in the next section.

### Second-Order Equations

The second-order linear equation with constant coefficients  $y_{n+2} + ay_{n+1} + by_n = f_n$  is solved by first solving the homogeneous equation (with right-hand side zero) and adding to that solution any solution of the inhomogeneous equation. The *homogeneous equation*  $y_{n+2} + ay_{n+1} + by_n = 0$  is solved by assuming  $y_n = \lambda^n$ , whereupon  $\lambda^{n+2} + a\lambda^{n+1} + b\lambda^n = 0$  or  $\lambda = 0$  (rejected) or  $\lambda^2 + a\lambda + b = 0$ . The roots of this quadratic are  $\lambda_1 = 1/2(-a + \sqrt{a^2 - 4b})$ ,  $\lambda_2 = 1/2(-a - \sqrt{a^2 - 4b})$  and the solution of the homogeneous equation is  $y_n = c_1\lambda_1^n + c_2\lambda_2^n$ . As an example consider the Fibonacci equation  $y_{n+2} - y_{n+1} - y_n = 0$ . The roots of  $\lambda^2 - \lambda - 1 = 0$  are  $\lambda_1 = 1/2(1 + \sqrt{5})$ ,  $\lambda_2 = 1/2(1 - \sqrt{5})$ , and the solution  $y_n = c_1[(1 + \sqrt{5})/2]^n + c_2[(1 - \sqrt{5})/2]^n$  is known as the *Fibonacci sequence*.

Many of the orthogonal polynomials of differential equations and numerical analysis satisfy a second-order difference equation (recurrence relation) involving a discrete variable, say  $n$ , and a continuous variable, say  $z$ . One such is the *Chebyshev equation*  $y_{n+2} - 2zy_{n+1} + y_n = 0$  with the initial conditions  $y_0 = 1$ ,  $y_1 = z$  (*first-kind* Chebyshev polynomials) and  $y_{n-1} = 0$ ,  $y_0 = 1$  (*second-kind* Chebyshev polynomials). They are denoted  $T_n(z)$  and  $V_n(z)$ , respectively. By iteration we find

$$T_0(z) = 1, \quad T_1(z) = z, \quad T_2(z) = 2z^2 - 1,$$

$$T_3(z) = 4z^3 - 3z, \quad T_4(z) = 8z^4 - 8z^2 + 1$$

$$V_0(z) = 0, \quad V_1(z) = 1, \quad V_2(z) = 2z,$$

$$V_3(z) = 4z^2 - 1, \quad V_4(z) = 8z^3 - 4z$$

and the general solution is  $y_n(z) = c_1 T_n(z) + c_2 V_{n-1}(z)$ ,

### Linear Equations with Constant Coefficients

The genral  $k$ th-order linear equation with constant coefficients is  $\sum_{i=0}^k p_i y_{n+k-i} = g_n, p_0 = 1$ . The solution to the corresponding homogeneous equation (obtained by setting  $g_n = 0$ ) is as follows. (a)  $y_n = \sum_{i=1}^k c_i \lambda_i^n$  if the  $\lambda_i$  are the distinct roots of the characteristic polynomial  $p(\lambda) = \sum_{i=0}^k p_i \lambda^{k-i} = 0$ . (b) if  $m_s$  is the multiplicity of the root  $\lambda_s$ , then the functions  $y_{n,s} = u_s(n) \lambda_s^n$ , where  $u_s(n)$  are polynomials in  $n$  whose degree does not exceed  $m_s - 1$ , are solutions of the equation. Then the general solution of the homogeneous equation is  $y_n = \sum_{i=1}^d a_i u_i(n) \lambda_i^n = \sum_{i=1}^d a_i \sum_{j=0}^{m_i-1} c_j n^j \lambda_i^n$ . To this solution one adds any particular solution to obtain the general solution of the general equation.

**Example 19.4.1.** A model equation for the price  $p_n$  of a product, at the  $n$ th time, is  $p_n + b/a(1 + \rho)p_{n-1} - (b/a)\rho p_{n-2} + (s_0 - d_0)/a = 0$ . The equilibrium price is obtained by setting  $p_n = p_{n-1} = p_{n-2} = p_e$ , and one finds  $p_e = (d_0 - s_0)/(a + b)$ . The homogeneous equation has the characteristic polynomial  $\lambda^2 + (b/a)(1 + \rho)\lambda - (b/a)\rho = 0$ . With  $\lambda_1$  and  $\lambda_2$  as the roots the general solution of the full equation is  $p_n = c_1 \lambda_1^n + c_2 \lambda_2^n + p_e$ , since  $p_e$  is a solution of the full equation. This is one method for finding the solution of the nonhomogeneous equation.

### Generating Function (z Transform)

An elegant way of solving linear difference equations with constant coefficients, among other applications, is by use of *generating functions* or, as an alternative, the  $z$  transform. The generating function of a sequence  $\{y_n\}, n = 0, 1, 2, \dots$ , is the function  $f(x)$  given by the formal series  $f(x) = \sum_{n=0}^{\infty} y_n x^n$ . The  $z$  transform of the same sequence is  $z(x) = \sum_{n=0}^{\infty} y_n x^{-n}$ . Clearly,  $z(x) = f(1/x)$ . A table of some important sequences is given in Table 19.4.1.

**Table 19.4.1 Important Sequences**

$y_n$	$f(x)$	Convergence Domain
1	$(1 - x)^{-1}$	$ x  < 1$
$n$	$x(1 - x)^{-2}$	$ x  < 1$
$n^n$	$x p_m(x) (1 - x)^{-n-1}$ *	$ x  < 1$
$k^n$	$(1 - kx)^{-1}$	$ x  < k^{-1}$
$e^{an}$	$(1 - e^a x)^{-1}$	$ x  < e^{-a}$
$k^n \cos an$	$\frac{1 - kx \cos a}{1 - 2kx \cos a + k^2 x^2}$	$ x  < k^{-1}$
$k^n \sin an$	$\frac{kx \sin a}{1 - 2kx \cos a + k^2 x^2}$	$ x  < k^{-1}$
$\binom{n}{m}$	$x^m (1 - x)^{-m-1}$	$ x  < 1$
$\binom{k}{n}$	$(1 + x)^k$	$ x  < 1$

\* The term  $p_m(z)$  is a polynomial of degree  $m$  satisfying  $p_{m+1}(z) = (mz + 1) \cdot p_m(z) + z(1 - z) p'_m(x), p_1 = 1$ .

To solve the linear difference equation  $\sum_{i=0}^k p_i y_{n+k-i} = 0$ ,  $p_0 = 1$  we associate with it the two formal series  $P = p_0 + p_1x + \dots + p_kx^k$  and  $Y = y_0 + y_1x + y_2x^2 + \dots$ . If  $p(x)$  is the characteristic polynomial then  $P(x) = x^k p(1/x) = \bar{p}(x)$ . The product of the two series is  $Q = YP = q_0 + q_1x + \dots + q_{k-1}x^{k-1} + q_kx^k + \dots$  where  $q_n = \sum_{i=0}^n p_i y_{n-i}$ . Because  $p_{k+1} = p_{k+2} = \dots = 0$ , it is obvious that  $q_{k+1} = q_{k+2} = \dots = 0$  — that is,  $Q$  is a polynomial (formal series with finite number of terms). Then  $Y = P^{-1}Q = q(x)/\bar{p}(x) = q(x)/x^k p(1/x)$ , where  $p$  is the characteristic polynomial and  $q(x) = \sum_{i=0}^k q_i x^i$ . The roots of  $\bar{p}(x)$  are  $x_i^{-1}$  where the  $x_i$  are the roots of  $p(x)$ .

*Theorem 1.* If the roots of  $p(x)$  are less than one in absolute value, then  $Y(x)$  converges for  $|x| < 1$ .

*Theorem 2.* If  $p(x)$  has no roots greater than one in absolute value and those on the unit circle are simple roots, then the coefficients  $y_n$  of  $Y$  are bounded. Now  $q_k = g_0$ ,  $q_{n+k} = g_n$ , and  $Q(x) = Q_1(x) + x^k Q_2(x)$ . Hence  $\sum_{i=1}^{\infty} y_i x^i = [Q_1(x) + x^k Q_2(x)] / [\bar{p}(x)]$ .

**Example 19.4.2.** Consider the equation  $y_{n+1} + y_n = -(n+1)$ ,  $y_0 = 1$ . Here  $Q_1 = 1$ ,  $Q_2 = -\sum_{n=0}^{\infty} (n+1)x^n = -1/(1-x)^2$ .

$$G(x) = \frac{1-x/(1-x)^2}{1+x} = \frac{5}{4} \frac{1}{1+x} - \frac{1}{4} \frac{1}{1-x} - \frac{1}{2} \frac{x}{(1-x)^2}$$

Using the table term by term, we find  $\sum_{n=0}^{\infty} y_n x^n = \sum_{n=0}^{\infty} [5/4(-1)^n - 1/4 - 1/2 n] x^n$ , so  $y_n = 5/4(-1)^n - 1/4 - 1/2 n$ .

## 19.5 Differential Equations

William F. Ames

Any equation involving derivatives is called a *differential equation*. If there is only one independent variable the equation is termed a *total differential equation* or an *ordinary differential equation*. If there is more than one independent variable the equation is called a *partial differential equation*. If the highest-order derivative is the  $n$ th then the equation is said to be  $n$ th order. If there is no function of the dependent variable and its derivatives other than the linear one, the equation is said to be *linear*. Otherwise, it is *nonlinear*. Thus  $(d^3y/dx^3) + a(dy/dx) + by = 0$  is a *linear* third-order ordinary (total) differential equation. If we replace  $by$  with  $by^3$ , the equation becomes nonlinear. An example of a second-order linear partial differential equation is the famous wave equation  $(\partial^2u/\partial x^2) - a^2(\partial^2u/\partial t^2) = f(x)$ . There are two independent variables  $x$  and  $t$  and  $a^2 > 0$  (of course). If we replace  $f(x)$  by  $f(u)$  (say  $u^3$  or  $\sin u$ ) the equation is nonlinear. Another example of a nonlinear third-order partial differential equation is  $u_t + uu_x = au_{xxx}$ . This chapter uses the common subscript notation to indicate the partial derivatives.

Now we briefly indicate some methods of solution and the solution of some commonly occurring equations.

### Ordinary Differential Equations

#### First-Order Equations

The *general* first-order equation is  $f(x, y, y') = 0$ . Equation capable of being written in either of the forms  $y' = f(x)g(y)$  or  $f(x)g(y)y' + F(x)G(y) = 0$  are *separable* equations. Their solution is obtained by using  $y' = dy/dx$  and writing the equations in differential form as  $dy/g(y) = f(x)dx$  or  $g(y)[dy/G(y)] = -F(x)[dx/f(x)]$  and integrating. An example is the famous *logistic* equation of inhibited growth  $(dy/dt) = ay(1 - y)$ . The integral of  $dy/y(1 - y) = adt$  is  $y = 1/[1 + (y_0^{-1} - 1)e^{-at}]$  for  $t \geq 0$  and  $y(0) = y_0$  (the initial state called the *initial condition*).

Equations may not have unique solutions. An example is  $y' = 2y^{1/2}$  with the initial condition  $y(0) = 0$ . One solution by separation is  $y = x^2$ . But there are an *infinity* of others — namely,  $y_a(x) = 0$  for  $-\infty < x \leq a$ , and  $(x - a)^2$  for  $a \leq x < \infty$ .

If the equation  $P(x, y)dy + Q(x, y)dy = 0$  is reducible to

$$\frac{dy}{dx} = f\left(\frac{y}{x}\right) \quad \text{or} \quad \frac{dy}{dx} = f\left(\frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}\right)$$

the equation is called *homogenous* (nearly homogeneous). The first form reduces to the separable equation  $u + x(du/dx) = f(u)$  with the substitution  $y/x = u$ . The nearly homogeneous equation is handled by setting  $x = X + \alpha$ ,  $y = Y + \beta$ , and choosing  $\alpha$  and  $\beta$  so that  $a_1\alpha + b_1\beta + c_1 = 0$  and  $a_2\alpha + b_2\beta + c_2 = 0$ . If

$\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} \neq 0$  this is always possible; the equation becomes  $dY/dX = [a_1 + b_1(Y/X)]/[a_2 + b_2(Y/X)]$  and

the substitution  $Y = Xu$  gives a separable equation. If  $\begin{vmatrix} a_1 & b_1 \\ a_2 & b_2 \end{vmatrix} = 0$  then  $a_2x + b_2y = k(a_1x + b_1y)$  and

the equation becomes  $du/dx = a_1 + b_1(u + c_1)/(ku + c_2)$ , with  $u = a_1x + b_1y$ . Lastly, any equation of the form  $dy/dx = f(ax + by + c)$  transforms into the separable equation  $du/dx = a + bf(u)$  using the change of variable  $u = ax + by + c$ .

The general first-order linear equation is expressible in the form  $y' + f(x)y = g(x)$ . It has the *general solution* (a solution with an arbitrary constant  $c$ )

$$y(x) = \exp\left[-\int f(x) dx\right] \left\{ c + \int \exp[f(x)]g(x) dx \right\}$$

Two noteworthy examples of first-order equations are as follows:

1. An often-occurring nonlinear equation is the *Bernoulli equation*,  $y' + p(x)y = g(x)y^\alpha$ , with  $\alpha$  real,  $\alpha \neq 0$ ,  $\alpha \neq 1$ . The transformation  $z = y^{1-\alpha}$  converts the equation to the linear first-order equation  $z' + (1 - \alpha)p(x)z = (1 - \alpha)q(x)$ .
2. The famous *Riccati equation*,  $y' = p(x)y^2 + q(x)y + r(x)$ , cannot in general be solved by integration. But some useful transformations are helpful. The substitution  $y = y_1 + u$  leads to the equation  $u' - (2py_1 + q)u = pu^2$ , which is a Bernoulli equation for  $u$ . The substitution  $y = y_1 + v^{-1}$  leads to the equation  $v' + (2py_1 + q)v + p = 0$ , which is a linear first-order equation for  $v$ . Once either of these equations has been solved, the general solution of the Riccati equation is  $y = y_1 + u$  or  $y = y_1 + v^{-1}$ .

### Second-Order Equations

The simplest of the second-order equations is  $y'' + ay' + by = 0$  ( $a, b$  real), with the initial conditions  $y(x_0) = y_0, y'(x_0) = y'_0$  or the boundary conditions  $y(x_0) = y_0, y(x_1) = y_1$ . The general solution of the equation is given as follows.

1.  $a^2 - 4b > 0, \lambda_1 = 1/2(-a + \sqrt{a^2 - 4b}), \lambda_2 = 1/2(-a - \sqrt{a^2 - 4b})$   
 $y = c_1 \exp(\lambda_1 x) + c_2 \exp(\lambda_2 x)$
2.  $a^2 - 4b = 0, \lambda_1 = \lambda_2 = -a/2, y = (c_1 + c_2 x) \exp(\lambda_1 x)$
3.  $a^2 - 4b < 0, \lambda_1 = 1/2(-a + i\sqrt{4b - a^2}), \lambda_2 = 1/2(-a - i\sqrt{4b - a^2}),$   
 $i^2 = -1$   
 With  $p = -a/2$  and  $q = 1/2 \sqrt{4b - a^2}$ ,

$$y = c_1 \exp[(p + iq)x] + c_2 \exp[(p - iq)x] = \exp(px)[A \sin qx + B \cos qx]$$

The initial conditions or boundary conditions are used to evaluate the arbitrary constants  $c_1$  and  $c_2$  (or  $A$  and  $B$ ).

Note that a linear problem with specified data may not have a solution. This is especially serious if numerical methods are employed without serious thought.

For example, consider  $y'' + y = 0$  with the boundary condition  $y(0) = 1$  and  $y(\pi) = 1$ . The general solution is  $y = c_1 \sin x + c_2 \cos x$ . The first condition  $y(0) = 1$  gives  $c_2 = 1$ , and the second condition requires  $y(\pi) = c_1 \sin \pi + \cos \pi$  or “ $1 = -1$ ,” which is a *contradiction*.

**Example 19.5.1 — The Euler Strut.** When a strut of uniform construction is subject to a compressive load  $P$  it exhibits no transverse displacement until  $P$  exceeds some critical value  $P_1$ . When this load is exceeded, buckling occurs and large deflections are produced as a result of small load changes. Let the rod of length  $\ell$  be placed as shown in [Figure 19.5.1](#).

FIGURE 19.5.1

From the linear theory of elasticity (Timoshenko), the transverse displacement  $y(x)$  satisfies the linear second-order equation  $y'' + (Py/EI) = 0$ , where  $E$  is the modulus of elasticity and  $I$  is the moment of inertia of the strut. The boundary conditions are  $y(0) = 0$  and  $y(a) = 0$ . With  $k^2 = P/EI$  the general solution is  $y = c_1 \sin kx + c_2 \cos kx$ . The condition  $y(0) = 0$  gives  $c_2 = 0$ . The second condition gives  $c_1 \sin ka = 0$ . Since  $c_1 = 0$  gives the trivial solution  $y = 0$  we must have  $\sin ka = 0$ . This occurs for  $ka = n\pi$ ,  $n = 0, 1, 2, \dots$  (these are called *eigenvalues*). The first nontrivial solution occurs for  $n = 1$  — that is,  $k = \pi/a$  — whereupon  $y_1 = c_1 \sin(\pi/a)$ , with arbitrary  $c_1$ . Since  $P = EI k^2$  the critical compressive load is  $P_1 = EI \pi^2/a^2$ . This is the buckling load. The weakness of the linear theory is its failure to model the situation when buckling occurs.

**Example 19.5.2 — Some Solvable Nonlinear Equations.** Many physical phenomena are modeled using nonlinear second-order equations. Some general cases are given here.

1.  $y'' = f(y)$ , first integral  $(y')^2 = 2 \int f(y) dy + c$ .
2.  $f(x, y', y'') = 0$ . Set  $p = y'$  and obtain a first-order equation  $f(x, p, dp/dx) = 0$ . Use first-order methods.
3.  $f(y, y', y'') = 0$ . Set  $p = y'$  and then  $y'' = p(dp/dy)$  so that a first-order equation  $f[y, p, p(dp/dy) = 0$  for  $p$  as a function of  $y$  is obtained.
4. The *Riccati transformation*  $du/dx = yu$  leads to the Riccati chain of equations, which linearize by raising the order. Thus,

Equation in $y$	Equation in $u$
1. $y' + y^2 = f(x)$	$u'' = f(x)u$
2. $y'' + 3yy' + y^3 = f(x)$	$u''' = f(x)u$
3. $y''' + 6y^2y' + 3(y')^2 + 4yy'' = f(x)$	$u^{(iv)} = f(x)u$

This method can be generalized to  $u' = a(x)yu$  or  $u' = a(x)f(u)y$ .

### Second-Order Inhomogeneous Equations

The general solution of  $a_0(x)y'' + a_1(x)y' + a_2(x)y = f(x)$  is  $y = y_H(x) + y_p(x)$  where  $y_H(x)$  is the general solution of the homogeneous equation (with the right-hand side zero) and  $y_p$  is the particular integral of the equation. Construction of particular integrals can sometimes be done by the *method of undetermined coefficients*. See Table 19.5.1. This applies only to the linear constant coefficient case in which the function  $f(x)$  is a linear combination of a polynomial, exponentials, sines and cosines, and some products of these functions. This method has as its base the observation that repeated differentiation of such functions gives rise to similar functions.

**Table 19.5.1 Method of Undetermined Coefficients — Equation  $L(y) = f(x)$  (Constant Coefficients)**

Terms in $f(x)$	Terms To Be Included in $y_p(x)$
1. Polynomial of degree $n$	(i) If $L(y)$ contains $y$ , try $y_p = a_0x^n + a_1x^{n-1} + \dots + a_n$ . (ii) If $L(y)$ does not contain $y$ and lowest-order derivative is $y^{(r)}$ , try $y_p = a_0x^{n+r} + \dots + a_nx^r$ .
2. $\sin qx, \cos qx$	(i) $\sin qx$ and/or $\cos qx$ are not in $y_H$ ; $y_p = B \sin qx + C \cos qx$ . (ii) $y_H$ contains terms of form $x^r \sin qx$ and/or $x^r \cos qx$ for $r = 0, 1, \dots, m$ ; include in $y_p$ terms of the form $a_0x^{m+1} \sin qx + a_1x^{m+1} \cos qx$ .
3. $e^{ax}$	(i) $y_H$ does not contain $e^{ax}$ ; include $Ae^{ax}$ in $y_p$ . (ii) $y_H$ contains $e^{ax}, xe^{ax}, \dots, x^m e^{ax}$ ; include in $y_p$ terms of the form $Ax^{m+1}e^{ax}$ .
4. $e^{px} \sin qx, e^{px} \cos qx$	(i) $y_H$ does not contain these terms; in $y_p$ include $Ae^{px} \sin qx + Be^{px} \cos qx$ . (ii) $y_H$ contains $x^r e^{px} \sin qx$ and/or $x^r e^{px} \cos qx$ ; $r = 0, 1, \dots, m$ include in $y_p$ . $Ax^{m+1}e^{px} \sin qx + Bx^{m+1}e^{px} \cos qx$ .

**Example 19.5.3.** Consider the equation  $y'' + 3y' + 2y = \sin 2x$ . The characteristic equation of the homogeneous equation  $\lambda^2 + 3\lambda + 2 = 0$  has the two roots  $\lambda_1 = -1$  and  $\lambda_2 = -2$ . Consequently,  $y_H = c_1e^{-x} + c_2e^{-2x}$ . Since  $\sin 2x$  is not linearly dependent on the exponentials and since  $\sin 2x$  repeats after two

differentiations, we assume a particular solution with undetermined coefficients of the form  $y_p(x) = B \sin 2x + C \cos 2x$ . Substituting into the original equation gives  $-(2B + 6C) \sin 2x + (6B - 2C) \cos 2x = \sin 2x$ . Consequently,  $-(2B + 6C) = 1$  and  $6B - 2C = 0$  to satisfy the equation. These two equations in two unknowns have the solution  $B = -1/20$  and  $C = -3/20$ . Hence  $y_p = -1/20 (\sin 2x + 3 \cos 2x)$  and  $y = c_1 e^{-x} + c_2 e^{-2x} - 1/20 (\sin 2x + 3 \cos 2x)$ .

A general method for finding  $y_p(x)$  called *variation of parameters* uses as its starting point  $y_H(x)$ . This method applies to *all* linear differential equations irrespective of whether they have constant coefficients. But it assumes  $y_H(x)$  is known. We illustrate the idea for  $a(x)y'' + b(x)y' + c(x)y = f(x)$ . If the solution of the homogeneous equation is  $y_H(x) = c_1\phi_1(x) + c_2\phi_2(x)$ , then vary the parameters  $c_1$  and  $c_2$  to seek  $y_p(x)$  as  $y_p(x) = u_1(x)\phi_1(x) + u_2(x)\phi_2(x)$ . Then  $y'_p = u_1\phi'_1 + u_2\phi'_2 + u'_1\phi_1 + u'_2\phi_2$  and choose  $u'_1\phi_1 + u'_2\phi_2 = 0$ . Calculating  $y''_p$  and setting in the original equation gives  $a(x)u'_1\phi'_1 + a(x)u'_2\phi'_2 = f$ . Solving the last two equations for  $u'_1$  and  $u'_2$  gives  $u'_1 = -\phi_2 f/wa$ ,  $u'_2 = \phi_1 f/wa$ , where  $w = \phi_1\phi'_2 - \phi'_1\phi_2 \neq 0$ . Integrating the general solution gives  $y = c_1\phi_1(x) + c_2\phi_2(x) - \left\{ \int [\phi_2 f(x)]/wa \right\} \phi_1(x) + \left\{ \int [\phi_1 f(x)]/wa \right\} \phi_2(x)$ .

**Example 19.5.4.** Consider the equations  $y'' - 4y = \sin x/(1 + x^2)$  and  $y_H = c_1 e^{-2x} + c_2 e^{2x}$ . With  $\phi_1 = e^{2x}$ , and  $\phi_2 = e^{-2x}$ ,  $w = 4$ , so the general solution is

$$y = c_1 e^{2x} + c_2 e^{-2x} - \frac{e^{-2x}}{4} \int \frac{e^{2x} \sin x}{1 + x^2} dx + \frac{e^{2x}}{4} \int \frac{e^{-2x} \sin x}{1 + x^2} dx$$

The method of variation of parameters can be generalized as described in the references.

Higher-order systems of linear equations with constant coefficients are treated in a similar manner. Details can be found in the references.

### Series Solution

The solution of differential equations can only be obtained in closed form in special cases. For all others, series or approximate or numerical solutions are necessary. In the simplest case, for an initial value problem, the solution can be developed as a Taylor series expansion about the point where the initial data are specified. The method fails in the *singular case* — that is, a point where the coefficient of the highest-order derivative is zero. The general method of approach is called the *Frobenius method*.

To understand the nonsingular case consider the equation  $y'' + xy = x^2$  with  $y(2) = 1$  and  $y'(2) = 2$  (an initial value problem). We seek a series solution of the form  $y(x) = a_0 + a_1(x - 2) + a_2(x - 2)^2 + \dots$ . To proceed, set  $1 = y(2) = a_0$ , which evaluates  $a_0$ . Next  $y'(x) = a_1 + 2a_2(x - 2) + \dots$ , so  $2 = y'(2) = a_1$  or  $a_1 = 2$ . Next  $y''(x) = 2a_2 + 6a_3(x - 2) + \dots$ , and from the equation,  $y'' = x^2 - xy$ , so  $y''(2) = 4 - 2y(2) = 4 - 2 = 2$ . Hence  $2 = 2a_2$  or  $a_2 = 1$ . Thus, to third-order  $y(x) = 1 + 2(x - 2) + (x - 2)^2 + R_2(x)$ , where the remainder  $R_2(x) = [(x - 2)^3/3]y'''(\xi)$ , where  $2 < \xi < x$  can be bounded for each  $x$  by finding the maximum of  $y'''(x) = 2x - y - xy'$ . The third term of the series follows by evaluating  $y'''(2) = 4 - 1 - 2 \cdot 2 = -1$ , so  $6a_3 = -1$  or  $a_3 = -1/6$ .

By now the nonsingular process should be familiar. The algorithm for constructing a series solution about a nonsingular (ordinary) point  $x_0$  of the equation  $P(x)y'' + Q(x)y' + R(x)y = f(x)$  (note that  $P(x_0) \neq 0$ ) is as follows:

1. Substitute into the differential equation the expressions

$$y(x) = \sum_{n=0}^{\infty} a_n (x - x_0)^n, \quad y'(x) = \sum_{n=1}^{\infty} n a_n (x - x_0)^{n-1}, \quad y''(x) = \sum_{n=2}^{\infty} n(n-1) a_n (x - x_0)^{n-2}$$

2. Expand  $P(x)$ ,  $Q(x)$ ,  $R(x)$ , and  $f(x)$  about the point  $x_0$  in a power series in  $(x - x_0)$  and substitute these series into the equation.
3. Gather all terms involving the same power of  $(x - x_0)$  to arrive at an identity of the form  $\sum_{n=0}^{\infty} A_n (x - x_0)^n \equiv 0$ .

4. Equate to zero each coefficient  $A_n$  of step 3.
5. Use the expressions of step 4 to determine  $a_2, a_3, \dots$  in terms of  $a_0, a_1$  (we need two arbitrary constants) to arrive at the general solution.
6. With the given initial conditions, determine  $a_0$  and  $a_1$ .

If the equation has a regular singular point — that is, a point  $x_0$  at which  $P(x)$  vanishes and a series expansion is sought about that point — a solution is sought of the form  $y(x) = (x - x_0)^r \sum_{n=0}^{\infty} a_n(x - x_0)^n$ ,  $a_0 \neq 0$  and the index  $r$  and coefficients  $a_n$  must be determined from the equation by an algorithm analogous to that already described. The description of this Frobenius method is left for the references.

## Partial Differential Equations

The study of partial differential equations is of continuing interest in applications. It is a vast subject, so the focus in this chapter will be on the most commonly occurring equations in the engineering literature — the second-order equations in two variables. Most of these are of the three basic types: elliptic, hyperbolic, and parabolic.

*Elliptic equations* are often called *potential equations* since they occur in potential problems where the potential may be temperature, voltage, and so forth. They also give rise to the steady solutions of parabolic equations. They require boundary conditions for the complete determination of their solution.

*Hyperbolic equations* are often called *wave equations* since they arise in the propagation of waves. For the development of their solutions, initial and boundary conditions are required. In principle they are solvable by the method of characteristics.

*Parabolic equations* are usually called *diffusion equations* because they occur in the transfer (diffusion) of heat and chemicals. These equations require initial conditions (for example, the initial temperature) and boundary conditions for the determination of their solutions.

Partial differential equations (PDEs) of the second order in two independent variables  $(x, y)$  are of the form  $a(x, y)u_{xx} + b(x, y)u_{xy} + c(x, y)u_{yy} = E(x, y, u, u_x, u_y)$ . If  $E = E(x, y)$  the equation is linear; if  $E$  depends also on  $u, u_x,$  and  $u_y,$  it is said to be *quasilinear*; and if  $E$  depends only on  $x, y,$  and  $u,$  it is *semilinear*. Such equations are classified as follows: If  $b^2 - 4ac$  is less than, equal to, or greater than zero at some point  $(x, y)$ , then the equation is elliptic, parabolic, or hyperbolic, respectively, at that point. A PDE of this form can be transformed into canonical (standard) forms by use of new variables. These standard forms are most useful in analysis and numerical computations.

For hyperbolic equations the standard form is  $u_{\xi\eta} = \phi(u, u_\eta, u_\xi, \eta, \xi)$ , where  $\xi_x/\xi_y = (-b + \sqrt{b^2 - 4ac})/2a$ , and  $\eta_x/\eta_y = (-b - \sqrt{b^2 - 4ac})/2a$ . The right-hand sides of these equations determine the so-called characteristics  $(dy/dx)_+ = (-b + \sqrt{b^2 - 4ac})/2a$ ,  $(dy/dx)_- = (-b - \sqrt{b^2 - 4ac})/2a$ .

**Example 19.5.5.** Consider the equation  $y^2u_{xx} - x^2u_{yy} = 0$ ,  $\xi_x/\xi_y = -x/y$ ,  $\eta_x/\eta_y = x/y$ , so  $\xi = y^2 - x^2$  and  $\eta = y^2 + x^2$ . In these new variables the equation becomes  $u_{\xi\eta} = (\xi u_\eta - \eta u_\xi)/2(\xi^2 - \eta^2)$ .

For parabolic equations the standard form is  $u_{\xi\xi} = \phi(u, u_\eta, u_\xi, \eta, \xi)$  or  $u_{\eta\eta} = \phi(u, u_\eta, u_\xi, \xi, \eta)$ , depending upon how the variables are defined. In this case  $\xi_x/\xi_y = -b/2a$  if  $a \neq 0$ , and  $\xi_x/\xi_y = -b/2c$  if  $c \neq 0$ . Only  $\xi$  must be determined (there is only one characteristic) and  $\eta$  can be chosen as any function that is linearly independent of  $\xi$ .

**Example 19.5.6.** Consider the equation  $y^2u_{xx} - 2xyu_{xy} + x^2u_{yy} + u_y = 0$ . Clearly,  $b^2 - 4ac = 0$ . Neither  $a$  nor  $c$  is zero so either path can be chosen. With  $\xi_x/\xi_y = -b/2a = x/y$ , there results  $\xi = x^2 + y^2$ . With  $\eta = x$ , the equation becomes  $u_{\eta\eta} = [2(\xi + \eta)u_\xi + u_\eta]/(\xi - \eta^2)$ .

For *elliptic equations* the standard form is  $u_{\alpha\alpha} + u_{\beta\beta} = \phi(u, u_\alpha, u_\beta, \alpha, \beta)$ , where  $\xi$  and  $\eta$  are determined by solving the  $\xi$  and  $\eta$  equations of the hyperbolic system (they are complex) and taking  $\alpha = (\eta + \xi)/2$ ,  $\beta = (\eta - \xi)/2i$  ( $i^2 = -1$ ). Since  $\xi$  and  $\eta$  are complex conjugates, both  $\alpha$  and  $\beta$  are real.

**Example 19.5.7.** Consider the equation  $y^2u_{xx} + x^2u_{yy} = 0$ . Clearly,  $b^2 - 4ac < 0$ , so the equation is elliptic. Then  $\xi_x/\xi_y = -ix/y$ ,  $\eta_x/\eta_y = ix/y$ , so  $\alpha = (\eta + \xi)/2 = y^2$  and  $\beta = (\eta - \xi)/2i = x^2$ . The standard form is  $u_{\alpha\alpha} + u_{\beta\beta} = -(u_\alpha/2\alpha + u_\beta/2\beta)$ .

Figure 19.5.5

**FIGURE 19.5.2 to 19.5.5** The mathematical equations used to generate these three-dimensional figures are worth a thousand words. The figures shown illustrate some of the nonlinear ideas of engineering, applied physics, and chemistry. [Figure 19.5.2](#) represents a breather soliton surface for the sine-Gordon equation  $w_{uv} = \sin w$  generated by a Backlund transformation. A single-soliton surface for the sine-Gordon equation  $w_{uv} = \sin w$  is illustrated in [Figure 19.5.3](#). [Figure 19.5.4](#) represents a single-soliton surface for the Tzitzecia-Dodd-Bullough equation associated with an integrable anisotropic gas dynamics system. [Figure 19.5.5](#) represents a single-soliton Bianchi surface.

The solutions to the equations were developed by W. K. Schief and C. Rogers at the Center for Dynamical Systems and Nonlinear Studies at the Georgia Institute of Technology and the University of New South Wales in Sydney, Australia. All of these three-dimensional projections were generated using the MAPLE software package. (Figures courtesy of Schief and Rogers).

## Methods of Solution

*Separation of Variables.* Perhaps the most elementary method for solving linear PDEs with homogeneous boundary conditions is the method of *separation of variables*. To illustrate, consider  $u_t - u_{xx} = 0$ ,  $u(x, 0) = f(x)$  (the initial condition) and  $u(0, t) = u(1, t) = 0$  for  $t > 0$  (the boundary conditions). A solution is assumed in “separated form”  $u(x, t) = X(x)T(t)$ . Upon substituting into the equation we find  $\dot{T}/T = X''/X$  (where  $\dot{T} = dT/dt$  and  $X'' = d^2X/dx^2$ ). Since  $T = T(t)$  and  $X = X(x)$ , the ratio must be constant, and for finiteness in  $t$  the constant must be negative, say  $-\lambda^2$ . The solutions of the separated equations  $X'' + \lambda^2 X = 0$  with the boundary conditions  $X(0) = 0$ ,  $X(1) = 0$ , and  $\dot{T} = -\lambda^2 T$  are  $X = A \sin \lambda x + B \cos \lambda x$  and  $T = C e^{-\lambda^2 t}$ , where  $A$ ,  $B$ , and  $C$  are arbitrary constants. To satisfy the boundary condition  $X(0) = 0$ ,  $B = 0$ . An infinite number of values of  $\lambda$  (eigenvalues), say  $\lambda_n = n\pi$  ( $n = 1, 2, 3, \dots$ ), permit all the eigenfunctions  $X_n = b_n \sin \lambda_n x$  to satisfy the other boundary condition  $X(1) = 0$ . The solution of the

equation and boundary conditions (not the initial condition) is, by superposition,  $u(x, t) = \sum_{n=1}^{\infty} b_n e^{-n^2 \pi^2 t} \cdot \sin n \pi x$  (a Fourier sine series), where the  $b_n$  are arbitrary. These values are obtained from the initial condition using the orthogonality properties of the trigonometric function (e.g.,  $\int_{-\pi}^{\pi} \sin mx \sin nx dx$  is 0 for  $m \neq n$  and is  $\pi$  for  $m = n \neq 0$ ) to be  $b_n = 2 \int_0^1 f(r) \sin n \pi r dr$ . Then the solution of the problem is  $u(x, t) = \sum_{n=1}^{\infty} [2 \int_0^1 f(r) \sin n \pi r dr] e^{-n^2 \pi^2 t} \sin n \pi x$ , which is a Fourier sine series.

If  $f(x)$  is a piecewise smooth or a piecewise continuous function defined for  $a \leq x \leq b$ , then its Fourier series within  $a \leq x \leq b$  as its fundamental interval (it is extended periodically outside that interval) is

$$f(x) \sim \frac{1}{2} a_0 + \sum_{n=1}^{\infty} a_n \cos[2n\pi x/(b-a)] + b_n \sin[2n\pi x/(b-a)]$$

where

$$a_n = \left[ \frac{2}{(b-a)} \right] \int_a^b f(x) \cos[2n\pi x/(b-a)] dx, \quad n = 0, 1, \dots$$

$$b_n = \left[ \frac{2}{(b-a)} \right] \int_a^b f(x) \sin[2n\pi x/(b-a)] dx, \quad n = 1, 2, \dots$$

The Fourier sine series has  $a_n \equiv 0$ , and the Fourier cosine series has  $b_n \equiv 0$ . The symbol  $\sim$  means that the series converges to  $f(x)$  at points of continuity, and at the (allowable) points of finite discontinuity the series converges to the *average value* of the discontinuous values.

*Caution:* This method *only* applies to linear equations with homogeneous boundary conditions. Linear equations with variable coefficients use other orthogonal functions, such as the Besel functions, Laguerre functions, Chebyshev functions, and so forth.

Some inhomogeneous boundary value problems can be transformed into homogeneous ones. Consider the problem  $u_t - u_{xx} = 0, 0 \leq x \leq 1, 0 \leq t < \infty$  with initial condition  $u(x, 0) = f(x)$ , and boundary conditions  $u(0, t) = g(t), u(1, t) = h(t)$ . To homogenize the boundary conditions set  $u(x, t) = w(x, t) + x[h(t) - g(t)] + g(t)$  and then solve  $w_t - w_{xx} = [\dot{g}(t) - \dot{h}(t)]x - \dot{g}(t)$  with the initial condition  $w(x, 0) = f(x) - x[h(0) - g(0)] + g(0)$  and  $w(0, t) = w(1, t) = 0$ .

*Operational Methods.* A number of integral transforms are useful for solving a variety of linear problems. To apply the Laplace transform to the problem  $u_t - u_{xx} = \delta(x) \delta(t), -\infty < x < \infty, 0 \leq t$  with the initial condition  $u(x, 0^-) = 0$ , where  $\delta$  is the Dirac delta function, we multiply by  $e^{-st}$  and integrate with respect to  $t$  from 0 to  $\infty$ . With the Laplace transform of  $u(x, t)$  denoted by  $U(x, s)$  — that is,  $U(x, s) = \int_0^{\infty} e^{-st} u(x, t) dt$  — we have  $sU - U_{xx} = \delta(x)$ , which has the solution

$$U(x, s) = A(s)e^{-x\sqrt{s}} + B(s)e^{x\sqrt{s}} \quad \text{for } x > 0$$

$$U(x, s) = C(s)e^{-x\sqrt{s}} + D(s)e^{x\sqrt{s}} \quad \text{for } x < 0$$

Clearly,  $B(s) = C(s) = 0$  for bounded solutions as  $|x| \rightarrow \infty$ . Then, from the boundary condition,  $U(0^+, s) - U(0^-, s) = 0$  and integration of  $sU - U_{xx} = \delta(x)$  from  $0^-$  to  $0^+$  gives  $U_x(0^+, s) - U_x(0^-, s) = -1$ , so  $A = D = 1/2 \sqrt{s}$ . Hence,  $U(x, s) = (1/2 \sqrt{s}) e^{-\sqrt{s}|x|}$  and the inverse is  $u(x, t) = (1/2 \pi i) \int_{\Gamma} e^{st} U(x, s) ds$ , where  $\Gamma$  is a Bromwich path, a vertical line taken to the right of all singularities of  $U$  on the sphere.

*Similarity (Invariance).* This very useful approach is related to dimensional analysis; both have their foundations in group theory. The three important transformations that play a basic role in Newtonian mechanics are translation, scaling, and rotations. Using two independent variables  $x$  and  $t$  and one dependent variable  $u = u(x, t)$ , the *translation group* is  $\bar{x} = x + \alpha a, \bar{t} = t + \beta a, \bar{u} = u + \gamma a$ ; the *scaling*

group is  $\bar{x} = a^\alpha x$ ,  $\bar{t} = a^\beta t$ , and  $\bar{u} = a^\gamma u$ ; the rotation group is  $\bar{x} = x \cos a + t \sin a$ ,  $\bar{t} = t \cos a - x \sin a$ ,  $\bar{u} = u$ , with a nonnegative real number  $a$ . Important in which follows are the invariants of these groups. For the translation group there are two  $\eta = x - \lambda t$ ,  $\lambda = \alpha/\beta$ ,  $f(\eta) = u - \varepsilon t$ ,  $\varepsilon = \gamma/\beta$  or  $f(\eta) = u - \theta x$ ,  $\theta = \gamma/\alpha$ ; for the scaling group the invariants are  $\eta = x/t^{\alpha/\beta}$  (or  $t/x^{\beta/\alpha}$ ) and  $f(\eta) = u/t^{\gamma/\beta}$  (or  $u/x^{\gamma/\alpha}$ ); for the rotation group the invariants are  $\eta = x^2 + t^2$  and  $u = f(\eta) = f(x^2 + t^2)$ .

If a PDE and its data (initial and boundary conditions) are left invariant by a transformation group, then similar (invariant) solutions are sought using the invariants. For example, if an equation is left invariant under scaling, then solutions are sought of the form  $u(x, t) = t^{\gamma/\beta} f(\eta)$ ,  $\eta = xt^{-\alpha/\beta}$  or  $u(x, t) = x^{\gamma/\alpha} f(tx^{-\beta/\alpha})$ ; invariance under translation gives solutions of the form  $u(x, t) = f(x - \lambda t)$ ; and invariance under rotation gives rise to solutions of the form  $u(x, t) = f(x^2 + t^2)$ .

Examples of invariance include the following:

1. The equation  $u_{xx} + u_{yy} = 0$  is invariant under rotation, so we search for solutions of the form  $u = f(x^2 + y^2)$ . Substitution gives the ODE  $f' + \eta f'' = 0$  or  $(\eta f')' = 0$ . The solution is  $u(x, t) = c \ln \eta = c \ln(x^2 + t^2)$ , which is the (so-called) fundamental solution of Laplace's equation.
2. The nonlinear diffusion equation  $u_t = (u^n u_x)_x$  ( $n > 0$ ),  $0 \leq x$ ,  $0 \leq t$ ,  $u(0, t) = ct^n$  is invariant under scaling with the similar form  $u(x, t) = t^n f(\eta)$ ,  $\eta = xt^{-(n+1)/2}$ . Substituting into the PDE gives the equation  $(f^n f')' + ((n + 1)/2)\eta f'' - n f = 0$ , with  $f(0) = c$  and  $f(\infty) = 0$ . Note that the equation is an ODE.
3. The wave equation  $u_{xx} - u_{tt} = 0$  is invariant under translation. Hence, solutions exist of the form  $u = f(x - \lambda t)$ . Substitution gives  $f''(1 - \lambda^2) = 0$ . Hence,  $\lambda = \pm 1$  or  $f$  is linear. Rejecting the trivial linear solution we see that  $u = f(x - t) + g(x + t)$ , which is the general (d'Alembert) solution of the wave equation; the quantities  $x - t = \alpha$ ,  $x + t = \beta$  are the characteristics of the next section.

The construction of all transformations that leave a PDE invariant is a solved problem left for the references.

The study of "solitons" (solitary traveling waves with special properties) has benefited from symmetry considerations. For example, the nonlinear third-order (Korteweg-de Vries) equation  $u_t + uu_x - au_{xxx} = 0$  is invariant under translation. Solutions are sought of the form  $u = f(x - \lambda t)$ , and  $f$  satisfies the ODE, in  $\eta = x - \lambda t$ ,  $-\lambda f' + ff' - af''' = 0$ .

*Characteristics.* Using the characteristics the solution of the hyperbolic problem  $u_{tt} - u_{xx} = p(x, t)$ ,  $-\infty < x < \infty$ ,  $0 \leq t$ ,  $u(x, 0) = f(x)$ ,  $u_t(x, 0) = h(x)$  is

$$u(x, t) = \frac{1}{2} \int_0^t d\tau \int_{x-(t-\tau)}^{x+(t-\tau)} p(\xi, \tau) d\xi + \frac{1}{2} \int_{x-t}^{x+t} h(\xi) d\xi + \frac{1}{2} [f(x+t) + f(x-t)]$$

The solution of  $u_{tt} - u_{xx} = 0$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ ,  $u(x, 0) = 0$ ,  $u_t(x, 0) = h(x)$ ,  $u(0, t) = 0$ ,  $t > 0$  is  $u(x, t) = 1/2 \int_{-x+t}^{x+t} h(\xi) d\xi$ .

The solution of  $u_{tt} - u_{xx} = 0$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ ,  $u(x, 0) = 0$ ,  $u_t(x, 0) = 0$ ,  $u(0, t) = g(t)$ ,  $t > 0$  is

$$u(x, t) = \begin{cases} 0 & \text{if } t < x \\ g(t - x) & \text{if } t > x \end{cases}$$

From time to time, lower-order derivatives appear in the PDE in use. To remove these from the equation  $u_{tt} - u_{xx} + au_x + bu_t + cu = 0$ , where  $a$ ,  $b$ , and  $c$  are constants, set  $\xi = x + t$ ,  $\mu = t - x$ , whereupon  $u(x, t) = u[(\xi - \mu)/2, (\xi + \mu)/2] = U(\xi, \mu)$ , where  $U_{\xi\mu} + [(b + a)/4] U_\xi + [(b - a)/4] U_\mu + (c/4)U = 0$ . The transformation  $U(\xi, \mu) = W(\xi, \mu) \exp[-(b - a)\xi/4 - (b + a)\mu/4]$  reduces to satisfying  $W_{\xi\mu} + \lambda W = 0$ , where  $\lambda = (a^2 - b^2 + 4c)/16$ . If  $\lambda \neq 0$ , we lose the simple d'Alembert solution. But the equation for  $W$  is still easier to handle.

In linear problems discontinuities propagate along characteristics. In nonlinear problems the situation is usually different. The characteristics are often used as new coordinates in the numerical method of characteristics.

*Green's Function.* Consider the diffusion problem  $u_t - u_{xx} = \delta(t)\delta(x - \xi)$ ,  $0 \leq x < \infty$ ,  $\xi > 0$ ,  $u(0, t) = 0$ ,  $u(x, 0) = 0$  [ $u(\infty, t) = u(\infty, 0) = 0$ ], a problem that results from a unit source somewhere in the domain subject to a homogeneous (zero) boundary condition. The solution is called a *Green's function of the first kind*. For this problem there is  $G_1(x, \xi, t) = F(x - \xi, t) - F(x + \xi, t)$ , where  $F(x, t) = e^{-x^2/4t} / \sqrt{4\pi t}$  is the *fundamental* (invariant) *solution*. More generally, the solution of  $u_t - u_{xx} = \delta(x - \xi) \delta(t - \tau)$ ,  $\xi > 0$ ,  $\tau > 0$ , with the same conditions as before, is the Green's function of the first kind.

$$G_1(x, \xi, t - \tau) = \frac{1}{\sqrt{4\pi(t - \tau)}} \left[ e^{-(x-\xi)^2/4(t-\tau)} - e^{-(x+\xi)^2/4(t-\tau)} \right]$$

for the semi-infinite interval.

The solution of  $u_t - u_{xx} = p(x, t)$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ , with  $u(x, 0) = 0$ ,  $u(0, t) = 0$ ,  $t > 0$  is  $u(x, t) = \int_0^t d\tau \int_0^\infty p(\xi, \tau) G_1(x, \xi, t - \tau) d\xi$ , which is a superposition. Note that the Green's function and the desired solution must both satisfy a zero boundary condition at the origin for this solution to make sense.

The solution of  $u_t - u_{xx} = 0$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ ,  $u(x, 0) = f(x)$ ,  $u(0, t) = 0$ ,  $t > 0$  is  $u(x, t) = \int_0^\infty f(\xi) G_1(x, \xi, t) d\xi$ .

The solution of  $u_t - u_{xx} = 0$ ,  $0 \leq x < \infty$ ,  $0 \leq t < \infty$ ,  $u(x, 0) = 0$ ,  $u(0, t) = g(t)$ ,  $t > 0$  (nonhomogeneous) is obtained by transforming to a new problem that has a homogeneous boundary condition. Thus, with  $w(x, t) = u(x, t) - g(t)$  the equation for  $w$  becomes  $w_t - w_{xx} = -\dot{g}(t) - g(0) \delta(t)$  and  $w(x, 0) = 0$ ,  $w(0, t) = 0$ . Using  $G_1$  above, we finally obtain  $u(x, t) = (x/\sqrt{4\pi}) \int_0^t g(t - \tau) e^{-x^2/4\tau} / \tau^{3/2} d\tau$ .

The Green's function approach can also be employed for elliptic and hyperbolic problems.

*Equations in Other Spatial Variables.* The spherically symmetric wave equation  $u_{rr} + 2u_r/r - u_{tt} = 0$  has the general solution  $u(r, t) = [f(t - r) + g(t + r)]/r$ .

The Poisson-Euler-Darboux equation, arising in gas dynamics,

$$u_{rs} + N(u_r + u_s)/(r + s) = 0$$

where  $N$  is a positive integer  $\geq 1$ , has the general solution

$$u(r, s) = k + \frac{\partial^{N-1}}{\partial r^{N-1}} \left[ \frac{f(r)}{(r + s)^N} \right] + \frac{\partial^{N-1}}{\partial s^{N-1}} \left[ \frac{g(s)}{(r + s)^N} \right]$$

Here,  $k$  is an arbitrary constant and  $f$  and  $g$  are arbitrary functions whose form is determined from the problem initial and boundary conditions.

*Conversion to Other Orthogonal Coordinate Systems.* Let  $(x^1, x^2, x^3)$  be rectangular (Cartesian) coordinates and  $(u^1, u^2, u^3)$  be any orthogonal coordinate system related to the rectangular coordinates by  $x^i = x^i(u^1, u^2, u^3)$ ,  $i = 1, 2, 3$ . With  $(ds)^2 = (dx^1)^2 + (dx^2)^2 + (dx^3)^2 = g_{11}(du^1)^2 + g_{22}(du^2)^2 + g_{33}(du^3)^2$ , where  $g_{ii} = (\partial x^1/\partial u^i)^2 + (\partial x^2/\partial u^i)^2 + (\partial x^3/\partial u^i)^2$ . In terms of these "metric" coefficients the basic operations of applied mathematics are expressible. Thus (with  $g = g_{11}g_{22}g_{33}$ )

$$dA = (g_{11}g_{22})^{1/2} du^1 du^2; \quad dV = (g_{11}g_{22}g_{33})^{1/2} du^1 du^2 du^3$$

$$\text{grad } \phi = \frac{\bar{a}_1}{(g_{11})^{1/2}} \frac{\partial \phi}{\partial u^1} + \frac{\bar{a}_2}{(g_{22})^{1/2}} \frac{\partial \phi}{\partial u^2} + \frac{\bar{a}_3}{(g_{33})^{1/2}} \frac{\partial \phi}{\partial u^3}$$

( $\bar{a}_i$  are unit vectors in direction  $i$ );

$$\text{div } \vec{E} = g^{-1/2} \left\{ \frac{\partial}{\partial u^1} \left[ (g_{22}g_{33})^{1/2} E_1 \right] + \frac{\partial}{\partial u^2} \left[ (g_{11}g_{33})^{1/2} E_2 \right] + \frac{\partial}{\partial u^3} \left[ (g_{11}g_{22})^{1/2} E_3 \right] \right\}$$

[here  $\vec{E} = (E_1, E_2, E_3)$ ];

$$\begin{aligned} \text{curl } \vec{E} = g^{-1/2} & \left\{ \bar{a}_1 (g_{11})^{1/2} \left( \frac{\partial}{\partial u^2} \left[ (g_{33})^{1/2} E_3 \right] - \frac{\partial}{\partial u^3} \left[ (g_{22})^{1/2} E_2 \right] \right) \right. \\ & + \bar{a}_2 (g_{22})^{1/2} \left( \frac{\partial}{\partial u^3} \left[ (g_{11})^{1/2} E_1 \right] - \frac{\partial}{\partial u^1} \left[ (g_{33})^{1/2} E_3 \right] \right) \\ & \left. + \bar{a}_3 (g_{33})^{1/2} \left( \frac{\partial}{\partial u^1} \left[ (g_{22})^{1/2} E_2 \right] - \frac{\partial}{\partial u^2} \left[ (g_{11})^{1/2} E_1 \right] \right) \right\} \end{aligned}$$

$$\text{div grad } \psi = \nabla^2 \psi = \text{Laplacian of } \psi = g^{-1/2} \sum_{i=1}^3 \frac{\partial}{\partial u^i} \left[ \frac{g^{1/2}}{g_{ii}} \frac{\partial \psi}{\partial u^i} \right]$$

Table 19.5.2 shows some coordinate systems.

**Table 19.5.2 Some Coordinate Systems**

Coordinate System	Metric Coefficients	
<b>Circular Cylindrical</b>		
$x = r \cos \theta$	$u^1 = r$	$g_{11} = 1$
$y = r \sin \theta$	$u^2 = \theta$	$g_{22} = r^2$
$z = z$	$u^3 = z$	$g_{33} = 1$
<b>Spherical</b>		
$x = r \sin \psi \cos \theta$	$u^1 = r$	$g_{11} = 1$
$y = r \sin \psi \sin \theta$	$u^2 = \psi$	$g_{22} = r^2$
$z = r \cos \psi$	$u^3 = \theta$	$g_{33} = r^2 \sin^2 \psi$
<b>Parabolic Coordinates</b>		
$x = \mu v \cos \theta$	$u^1 = \mu$	$g_{11} = \mu^2 + v^2$
$y = \mu v \sin \theta$	$u^2 = v$	$g_{22} = \mu^2 + v^2$
$z = 1/2 (\mu^2 - v^2)$	$u^3 = \theta$	$g_{33} = \mu^2 v^2$

Other metric coefficients and so forth can be found in Moon and Spencer [1961].

## 19.6 Integral Equations

William F. Ames

### Classification and Notation

Any equation in which the unknown function  $u(x)$  appears under the integral sign is called an *integral equation*. If  $f(x)$ ,  $K(x, t)$ ,  $a$ , and  $b$  are known then the integral equation for  $u$ ,  $\int_a^b K(x, t) u(t) dt = f(x)$  is called a *linear integral equation of the first kind of Fredholm type*.  $K(x, t)$  is called the *kernel function* of the equation. If  $b$  is replaced by  $x$  (the independent variable) the equation is an equation of *Volterra type of the first kind*.

An equation of the form  $u(x) = f(x) + \lambda \int_a^b K(x, t) u(t) dt$  is said to be a linear integral equation of *Fredholm type of the second kind*. If  $b$  is replaced by  $x$  it is of *Volterra type*. If  $f(x)$  is not present the equation is homogeneous.

The equation  $\phi(x) u(x) = f(x) + \lambda \int_a^{b \text{ or } x} K(x, t) u(t) dt$  is the *third kind equation* of Fredholm or Volterra type. If the unknown function  $u$  appears in the equation in any way other than to the first power then the integral equation is said to be *nonlinear*. Thus,  $u(x) = f(x) + \int_a^b K(x, t) \sin u(t) dt$  is nonlinear. An integral equation is said to be *singular* when either or both of the limits of integration are infinite or if  $K(x, t)$  becomes infinite at one or more points of the integration interval.

**Example 19.6.1.** Consider the singular equations  $u(x) = x + \int_0^\infty \sin(xt) u(t) dt$  and  $f(x) = \int_0^x [u(t)/(x-t)^2] dt$ .

### Relation to Differential Equations

The *Leibnitz rule*  $(d/dx) \int_{a(x)}^{b(x)} F(x, t) dt = \int_{a(x)}^{b(x)} (\partial F/\partial x) dt + F[x, b(x)](db/dx) - F[x, a(x)](da/dx)$  is useful for differentiation of an integral involving a parameter ( $x$  in this case). With this, one can establish the relation

$$I_n(x) = \int_a^x (x-t)^{n-1} f(t) dt = (n-1)! \underbrace{\int_a^x \dots \int_a^x}_{n \text{ times}} f(x) \underbrace{dx \dots dx}_{n \text{ times}}$$

This result will be used to establish the relation of the second-order initial value problem to a Volterra integral equation.

The second-order differential equation  $y''(x) + A(x)y'(x) + B(x)y = f(x)$ ,  $y(a) = y_0$ ,  $y'(a) = y'_0$  is equivalent to the integral equations

$$y(x) = - \int_a^x \{A(t) + (x-t)[B(t) - A'(t)]\} y(t) dt + \int_a^x (x-t)f(t) dt + [A(a)y_0 + y'_0](x-a) + y_0$$

which is of the type  $(x)y = \int_a^x K(x, t)y(t) dt + F(x)$  where  $K(x, t) = (t-x)[B(t) - A'(t)] - A(t)$  and  $F(x)$  includes the rest of the terms. Thus, this initial value problem is equivalent to a Volterra integral equation of the second kind.

**Example 19.6.2.** Consider the equation  $y'' + x^2y' + xy = x$ ,  $y(0) = 1$ ,  $y'(0) = 0$ . Here  $A(x) = x^2$ ,  $B(x) = x$ ,  $f(x) = x$ ,  $a = 0$ ,  $y_0 = 1$ ,  $y'_0 = 0$ . The integral equation is  $y(x) = \int_0^x t(x-2t)y(t) dt + (x^3/6) + 1$ .

The expression for  $I_n(x)$  can also be useful in converting boundary value problems to integral equations. For example, the problem  $y''(x) + \lambda y = 0$ ,  $y(0) = 0$ ,  $y(a) = 0$  is equivalent to the Fredholm equation  $y(x) = \lambda \int_0^a K(x, t)y(t) dt$ , where  $K(x, t) = (t/a)(a-x)$  when  $t < x$  and  $K(x, t) = (x/a)(a-t)$  when  $t > x$ .

In both cases the differential equation can be recovered from the integral equation by using the Leibnitz rule.

Nonlinear differential equations can also be transformed into integral equations. In fact this is one method used to establish properties of the equation and to develop approximate and numerical solutions. For example, the “forced pendulum” equation  $y''(x) + a^2 \sin y(x) = f(x)$ ,  $y(0) = y(1) = 0$  transforms into the nonlinear Fredholm equation.

$$y(x) = \int_0^1 K(x, t) [a^2 \sin y(t) - f(t)] dt$$

with  $K(x, t) = x(1 - t)$  for  $0 < x < t$  and  $K(x, t) = t(1 - x)$  for  $t < x < 1$ .

### Methods of Solution

Only the simplest integral equations can be solved exactly. Usually approximate or numerical methods are employed. The advantage here is that integration is a “smoothing operation,” whereas differentiation is a “roughening operation.” A few exact and approximate methods are given in the following sections. The numerical methods are found under 19.12.

### Convolution Equations

The special convolution equation  $y(x) = f(x) + \lambda \int_0^x K(x - t)y(t) dt$  is a special case of the Volterra equation of the second kind.  $K(x - t)$  is said to be a *convolution kernel*. The integral part is the convolution integral discussed under 19.8. The solution can be accomplished by transforming with the Laplace transform:  $L[y(x)] = L[f(x)] + \lambda L[y(x)]L[K(x)]$  or  $y(x) = L^{-1}\{L[f(x)]/(1 - \lambda L[K(x)])\}$ .

### Abel Equation

The Volterra equation  $f(x) = \int_0^x y(t)/(x - t)^\alpha dt$ ,  $0 < \alpha < 1$  is the (singular) Abel equation. Its solution is  $y(x) = (\sin \alpha\pi/\pi)(d/dx) \int_0^x F(t)/(x - t)^{1-\alpha} dt$ .

### Approximate Method (Picard’s Method)

This method is one of successive approximations that is described for the equation  $y(x) = f(x) + \lambda \int_a^x K(x, t)y(t) dt$ . Beginning with an initial guess  $y_0(t)$  (often the value at the initial point  $a$ ) generate the next approximation with  $y_1(x) = f(x) + \lambda \int_a^x K(x, t)y_0(t) dt$  and continue with the general iteration

$$y_n(x) = f(x) + \lambda \int_a^x K(x, t)y_{n-1}(t) dt$$

Then, by iterating, one studies the convergence of this process, as is described in the literature.

**Example 19.6.3.** Let  $y(x) = 1 + \int_0^x xt[y(t)]^2 dt$ ,  $y(0) = 1$ , With  $y_0(t) = 1$  we find  $y_1(x) = 1 + \int_0^x xt dt = 1 + (x^3/2)$  and  $y_2(x) = 1 + \int_0^x xt[1 + (t^3/2)^2]dt$ , and so forth.

## 19.7 Approximation Methods

*William F. Ames*

The term *approximation methods* usually refers to an analytical process that generates a symbolic approximation rather than a numerical one. Thus,  $1 + x + x^2/2$  is an approximation of  $e^x$  for small  $x$ . This chapter introduces some techniques for approximating the solution of various operator equations.

### Perturbation

#### Regular Perturbation

This procedure is applicable to *some* equations in which a small parameter,  $\epsilon$ , appears. Use this procedure with care; the procedure involves expansion of the dependent variables and data in a power series in the small parameter. The following example illustrates the procedure.

**Example 19.7.1.** Consider the equation  $y'' + \epsilon y' + y = 0$ ,  $y(0) = 1$ ,  $y'(0) = 0$ . Write  $y(x; \epsilon) = y_0(x) + \epsilon y_1(x) + \epsilon^2 y_2(x) + \dots$ , and the initial conditions (data) become

$$\begin{aligned} y_0(0) + \epsilon y_1(0) + \epsilon^2 y_2(0) + \dots &= 1 \\ y_0'(0) + \epsilon y_1'(0) + \epsilon^2 y_2'(0) + \dots &= 0 \end{aligned}$$

Equating like powers of  $\epsilon$  in all three equations yields the sequence of equations

$$\begin{aligned} \mathcal{O}(\epsilon^0): y_0'' + y_0 &= 0, & y_0(0) &= 1, & y_0'(0) &= 0 \\ \mathcal{O}(\epsilon^1): y_1'' + y_1 &= -y_0', & y_1(0) &= 0, & y_1'(0) &= 0 \\ & \vdots \end{aligned}$$

The solution for  $y_0$  is  $y_0 = \cos x$  and using this for  $y_1$  we find  $y_1(x) = 1/2 (\sin x - x \cos x)$ . So  $y(x; \epsilon) = \cos x + \epsilon(\sin x - x \cos x)/2 + \mathcal{O}(\epsilon^2)$ . Appearance of the term  $x \cos x$  indicates a *secular term* that becomes arbitrarily large as  $x \rightarrow \infty$ . Hence, this approximation is valid only for  $x \ll 1/\epsilon$  and for small  $\epsilon$ . If an approximation is desired over a larger range of  $x$  then the method of multiple scales is required.

#### Singular Perturbation

The *method of multiple scales* is a singular method that is *sometimes* useful if the regular perturbation method fails. In this case the assumption is made that the solution depends on *two* (or more) different length (or time) scales. By trying various possibilities, one can determine those scales. The scales are treated as dependent variables when transforming the given ordinary differential equation into a partial differential equation, but then the scales are treated as independent variables when solving the equations.

**Example 19.7.2.** Consider the equation  $\epsilon y'' + y' = 2$ ,  $y(0) = 0$ ,  $y(1) = 1$ . This is singular since (with  $\epsilon = 0$ ) the resulting first-order equation cannot satisfy both boundary conditions. For the problem the proper length scales are  $u = x$  and  $v = x/\epsilon$ . The second scale can be ascertained by substituting  $\epsilon^n x$  for  $x$  and requiring  $\epsilon y''$  and  $y'$  to be of the same order in the transformed equation. Then

$$\frac{d}{dx} = \frac{\partial}{\partial u} \frac{du}{dx} + \frac{\partial}{\partial v} \frac{dv}{dx} = \frac{\partial}{\partial u} + \frac{1}{\epsilon} \frac{\partial}{\partial v}$$

and the equation becomes

$$\epsilon \left( \frac{\partial}{\partial u} + \frac{1}{\epsilon} \frac{\partial}{\partial v} \right)^2 y + \left( \frac{\partial}{\partial u} + \frac{1}{\epsilon} \frac{\partial}{\partial v} \right) y = 2$$

With  $y(x; \epsilon) = y_0(u, v) + \epsilon y_1(u, v) + \epsilon^2 y_2(u, v) + \dots$  we have terms

$$O(\epsilon^{-1}): \frac{\partial^2 y_0}{\partial v^2} + \frac{\partial y_0}{\partial v} = 0 \quad (\text{actually ODEs with parameter } u)$$

$$O(\epsilon^0): \frac{\partial^2 y_1}{\partial v^2} + \frac{\partial y_1}{\partial v} = 2 - 2 \frac{\partial^2 y_0}{\partial u \partial v} - \frac{\partial y_0}{\partial u}$$

$$O(\epsilon^1): \frac{\partial^2 y_2}{\partial v^2} + \frac{\partial y_2}{\partial v} = -2 \frac{\partial^2 y_1}{\partial u \partial v} - \frac{\partial y_1}{\partial u} - \frac{\partial^2 y_0}{\partial u^2}$$

⋮

Then  $y_0(u, v) = A(u) + B(u)e^{-v}$  and so the second equation becomes  $\partial^2 y_1 / \partial v^2 + \partial y_1 / \partial v = 2 - A'(u) + B'(u)e^{-v}$ , with the solution  $y_1(u, v) = [2 - A'(u)]v + vB'(u)e^{-v} + D(u) + E(u)e^{-v}$ . Here  $A, B, D$  and  $E$  are still arbitrary. Now the solvability condition — “higher order terms must vanish no slower (as  $\epsilon \rightarrow 0$ ) than the previous term” (Kevorkian and Cole, 1981) — is used. For  $y_1$  to vanish no slower than  $y_0$  we must have  $2 - A'(u) = 0$  and  $B'(u) = 0$ . If this were not true the terms in  $y_1$  would be larger than those in  $y_0$  ( $v \gg 1$ ). Thus  $y_0(u, v) = (2u + A_0) + B_0 e^{-v}$ , or in the original variables  $y(x; \epsilon) \approx (2x + A_0) + B_0 e^{-x/\epsilon}$  and matching to both boundary conditions gives  $y(x; \epsilon) \approx 2x - (1 - e^{-x/\epsilon})$ .

### Boundary Layer Method

The boundary layer method is applicable to regions in which the solution is *rapidly varying*. See the references at the end of the chapter for detailed discussion.

### Iterative Methods

#### Taylor Series

If it is known that the solution of a differential equation has a power series in the independent variable ( $t$ ), then we may proceed from the initial data (the easiest problem) to compute the Taylor series by differentiation.

**Example 19.7.3.** Consider the equation  $(d^2x/dt^2) = -x - x^2$ ,  $x(0) = 1$ ,  $x'(0) = 1$ . From the differential equation,  $x''(0) = -2$ , and, since  $x''' = -x' - 2xx'$ ,  $x'''(0) = -1 - 2 = -3$ , so the four term approximation for  $x(t) \approx 1 + t - (2t^2/2!) - (3t^3/3!) = 1 + t - t^2 - t^3/2$ . An estimate for the error at  $t = t_1$ , (see a discussion of series methods in any calculus text) is not greater than  $|d^4x/dt^4|_{\max} [(t_1)^4/4!]$ ,  $0 \leq t \leq t_1$ .

#### Picard’s Method

If the vector differential equation  $x' = f(t, x)$ ,  $x(0)$  given, is to be approximated by Picard iteration, we begin with an initial guess  $x_0 = x(0)$  and calculate iteratively  $x'_i = f(t, x_{i-1})$ .

**Example 19.7.4.** Consider the equation  $x' = x + y^2$ ,  $y' = y - x^3$ ,  $x(0) = 1$ ,  $y(0) = 2$ . With  $x_0 = 1$ ,  $y_0 = 2$ ,  $x'_1 = 5$ ,  $y'_1 = 1$ , so  $x_1 = 5t + 1$ ,  $y_1 = t + 2$ , since  $x_i(0) = 1$ ,  $y_i(0) = 2$  for  $i \geq 0$ . To continue, use  $x'_{i+1} = x_i + y_i^2$ ,  $y'_{i+1} = y_i - x_i^3$ . A modification is the utilization of the first calculated term immediately in the second equation. Thus, the calculated value of  $x_1 = 5t + 1$ , when used in the second equation, gives  $y'_1 = y_0 - (5t + 1)^3 = 2 - (125t^3 + 75t^2 + 15t + 1)$ , so  $y_1 = 2t - (125t^4/4) - 25t^3 - (15t^2/2) - t + 2$ . Continue with the iteration  $x'_{i+1} = x_i + y_i^2$ ,  $y'_{i+1} = y_i - (x_{i+1})^3$ .

Another variation would be  $x'_{i+1} = x_{i+1} + (y_i)^2$ ,  $y'_{i+1} = y_{i+1} - (x_{i+1})^3$ .

## 19.8 Integral Transforms

### William F. Ames

All of the integral transforms are special cases of the equation  $g(s) = \int_a^b K(s, t)f(t)dt$ , in which  $g(s)$  is said to be the *transform* of  $f(t)$ , and  $K(s, t)$  is called the *kernel* of the transform. Table 19.8.1 shows the more important kernels and the corresponding intervals  $(a, b)$ .

Details for the first three transforms listed in Table 19.8.1 are given here. The details for the other are found in the literature.

### Laplace Transform

The Laplace transform of  $f(t)$  is  $g(s) = \int_0^\infty e^{-st} f(t) dt$ . It may be thought of as transforming one class of functions into another. The advantage in the operation is that under certain circumstances it replaces complicated functions by simpler ones. The notation  $L[f(t)] = g(s)$  is called the *direct transform* and  $L^{-1}[g(s)] = f(t)$  is called the *inverse transform*. Both the direct and inverse transforms are tabulated for many often-occurring functions. In general  $L^{-1}[g(s)] = (1/2\pi i) \int_{\alpha-i\infty}^{\alpha+i\infty} e^{st}g(s) ds$ , and to evaluate this integral requires a knowledge of complex variables, the theory of residues, and contour integration.

### Properties of the Laplace Transform

Let  $L[f(t)] = g(s)$ ,  $L^{-1}[g(s)] = f(t)$ .

1. The Laplace transform may be applied to a function  $f(t)$  if  $f(t)$  is continuous or piecewise continuous; if  $t^n|f(t)|$  is finite for all  $t$ ,  $t \rightarrow 0$ ,  $n < 1$ ; and if  $e^{-at}|f(t)|$  is finite as  $t \rightarrow \infty$  for some value of  $a$ ,  $a > 0$ .
2.  $L$  and  $L^{-1}$  are unique.
3.  $L[af(t) + bh(t)] = aL[f(t)] + bL[h(t)]$  (linearity).
4.  $L[e^{at}f(t)] = g(s - a)$  (shift theorem).
5.  $L[(-t)^k f(t)] = d^k g/ds^k$ ;  $k$  a positive integer.

**Example 19.8.1.**  $L[\sin at] = \int_0^\infty e^{-st} \sin at dt = a/(s^2 + a^2)$ ,  $s > 0$ . By property 5,

$$\int_0^\infty e^{-st} t \sin at dt = L[t \sin at] = \frac{2as}{s^2 + a^2}$$

**Table 19.8.1** Kernels and Intervals of Various Integral Transforms

Name of Transform	(a, b)	K(s, t)
Laplace	(0, ∞)	$e^{-st}$
Fourier	(-∞, ∞)	$\frac{1}{\sqrt{2\pi}} e^{-ist}$
Fourier cosine	(0, ∞)	$\sqrt{\frac{2}{\pi}} \cos st$
Fourier sine	(0, ∞)	$\sqrt{\frac{2}{\pi}} \sin st$
Mellin	(0, ∞)	$t^{s-1}$
Hankel	(0, ∞)	$tJ_\nu(st), \nu \geq -\frac{1}{2}$

$$L[f'(t)] = sL[f(t)] - f(0)$$

$$L[f''(t)] = s^2L[f(t)] - sf(0) - f'(0)$$

6.  $\vdots$

$$L[f^{(n)}(t)] = s^n L[f(t)] - s^{n-1}f(0) - \dots - sf^{(n-2)}(0) - f^{(n-1)}(0)$$

In this property it is apparent that the initial data are automatically brought into the computation.

**Example 19.8.2.** Solve  $y'' + y = e^t, y(0) = 1, y'(0) = 1$ . Now  $L[y''] = s^2L[y] - sy(0) - y'(0) = s^2L[y] - s - 1$ . Thus, using the linear property of the transform (property 3),  $s^2L[y] + L[y] - s - 1 = L[e^t] = 1/(s - 1)$ . Therefore,  $L[y] = s^2/[s(s - 1)(s^2 + 1)]$ .

With the notations  $\Gamma(n + 1) = \int_0^\infty x^n e^{-x} dx$  (gamma function) and  $J_n(t)$  the Bessel function of the first kind of order  $n$ , a short table of Laplace transforms is given in [Table 19.8.2](#).

$$7. \quad L\left[\int_a^t f(t) dt\right] = \frac{1}{s}L[f(t)] + \frac{1}{s}\int_a^0 f(t) dt.$$

**Example 19.8.3.** Find  $f(t)$  if  $L[f(t)] = (1/s^2)[1/(s^2 - a^2)]$ .  $L[1/a \sinh a t] = 1/(s^2 - a^2)$ . Therefore,  $f(t) = \int_0^t [\int_0^t \frac{1}{a} \sinh a t d t] d t = 1/a^2[(\sinh a t)/a - t]$ .

$$L\left[\frac{f(t)}{t}\right] = \int_s^\infty g(s) ds; \quad L\left[\frac{f(t)}{t^k}\right] = \underbrace{\int_s^\infty \dots \int_s^\infty}_{k \text{ integrals}} g(s)(ds)^k$$

**Example 19.8.4.**  $L[(\sin a t)/t] = \int_s^\infty L[\sin a t] d s = \int_s^\infty [a d s/(s^2 + a^2)] = \cot^{-1}(s/a)$ .

- 9. The unit step function  $u(t - a) = 0$  for  $t < a$  and 1 for  $t > a$ .  $L[u(t - a)] = e^{-as}/s$ .
- 10. The unit impulse function is  $\delta(a) = u'(t - a) = 1$  at  $t = a$  and 0 elsewhere.  $L[u'(t - a)] = e^{-as}$ .
- 11.  $L^{-1}[e^{-as}g(s)] = f(t - a)u(t - a)$  (second shift theorem).
- 12. If  $f(t)$  is periodic of period  $b$  — that is,  $f(t + b) = f(t)$  — then  $L[f(t)] = [1/(1 - e^{-bs})] \times \int_0^b e^{-st}f(t) dt$ .

**Example 19.8.5.** The equation  $\partial^2y/(\partial t \partial x) + \partial y/\partial t + \partial y/\partial x = 0$  with  $(\partial y/\partial x)(0, x) = y(0, x) = 0$  and  $y(t, 0) + (\partial y/\partial t)(t, 0) = \delta(0)$  (see property 10) is solved by using the Laplace transform of  $y$  with respect to  $t$ . With  $g(s, x) = \int_0^\infty e^{-st}y(t, x) dt$ , the transformed equation becomes

**Table 19.8.2 Some Laplace Transforms**

$f(t)$	$g(s)$	$f(t)$	$g(s)$
1	$\frac{1}{s}$	$e^{-at}(1 - a t)$	$\frac{s}{(s + a)^2}$
$t^n, n$ is a + integer	$\frac{n!}{s^{n+1}}$	$\frac{t \sin at}{2a}$	$\frac{s}{(s^2 + a^2)^2}$
$t^n, n \neq a +$ integer	$\frac{\Gamma(n + 1)}{s^{n+1}}$	$\frac{1}{2a^2} \sin at \sinh at$	$\frac{s}{s^4 + 4a^4}$
$\cos a t$	$\frac{s}{s^2 + a^2}$	$\cos a t \cosh a t$	$\frac{s^3}{s^4 + 4a^4}$
$\sin a t$	$\frac{a}{s^2 + a^2}$	$\frac{1}{2a}(\sinh at + \sin at)$	$\frac{s^2}{s^4 - a^4}$
$\cosh a t$	$\frac{s}{s^2 - a^2}$	$\frac{1}{2}(\cosh at + \cos at)$	$\frac{s^3}{s^4 - a^4}$
$\sinh a t$	$\frac{a}{s^2 - a^2}$	$\frac{\sin at}{t}$	$\tan^{-1} \frac{a}{s}$
$e^{-at}$	$\frac{1}{s + a}$	$J_0(a t)$	$\frac{1}{\sqrt{s^2 + a^2}}$
$e^{-bt} \cos a t$	$\frac{s + b}{(s + b)^2 + a^2}$	$\frac{n}{a^n} \frac{J_n(at)}{t}$	$\frac{1}{(\sqrt{s^2 + a^2} + s)^n}$
$e^{-bt} \sin a t$	$\frac{a}{(s + b)^2 + a^2}$	$J_0(2\sqrt{at})$	$\frac{1}{s} e^{-a/s}$

$$s \frac{\partial g}{\partial x} - \frac{\partial y}{\partial x}(0, x) + sg - y(0, x) + \frac{\partial g}{\partial x} = 0$$

or

$$(s + 1) \frac{\partial g}{\partial x} + sg = \frac{\partial y}{\partial x}(0, x) + y(0, x) = 0$$

The second (boundary) condition gives  $g(s, 0) + sg(s, 0) - y(0, 0) = 1$  or  $g(s, 0) = 1/(1 + s)$ . A solution of the preceding ordinary differential equation consistent with this condition is  $g(s, x) = [1/(s + 1)]e^{-sx/(s+1)}$ . Inversion of this transform gives  $y(t, x) = e^{-(t+x)}I_0(2/\sqrt{tx})$ , where  $I_0$  is the zero-order Bessel function of an imaginary argument.

### Convolution Integral

The *convolution integral* (*faltung*) of two functions  $f(t), r(t)$  is  $x(t) = f(t)*r(t) = \int_0^t f(\tau)r(t - \tau) d \tau$ .

**Example 19.8.6.**  $t * \sin t = \int_0^t \tau \sin(t - \tau) d \tau = t - \sin t$ .

13.  $L[f(t)]L[h(t)] = L[f(t) * h(t)]$ .

### Fourier Transform

The *Fourier transform* is given by  $F[f(t)] = (1/\sqrt{2\pi})\int_{-\infty}^{\infty} f(t)e^{-ist} d t = g(s)$  and its *inverse* by  $F^{-1}[g(s)] = (1/\sqrt{2\pi})\int_{-\infty}^{\infty} g(s)e^{ist} d t = f(t)$ . In brief, the condition for the Fourier transform to exist is that  $\int_{-\infty}^{\infty} |f(t)| d t < \infty$ , although certain functions may have a Fourier transform even if this is violated.

**Example 19.8.7.** The function  $f(t) = 1$  for  $-a \leq t \leq a$  and  $= 0$  elsewhere has

$$F[f(t)] = \int_{-a}^a e^{-ist} dt = \int_0^a e^{ist} dt + \int_0^a e^{-ist} dt = 2 \int_0^a \cos st dt = \frac{2 \sin sa}{s}$$

**Properties of the Fourier Transform**

Let  $F[f(t)] = g(s)$ ;  $F^{-1}[g(s)] = f(t)$ .

1.  $F[f^{(n)}(t)] = (i s)^n F[f(t)]$
2.  $F[af(t) + bh(t)] = aF[f(t)] + bF[h(t)]$
3.  $F[f(-t)] = g(-s)$
4.  $F[f(at)] = 1/a g(s/a), a > 0$
5.  $F[e^{-iwt}f(t)] = g(s + w)$
6.  $F[f(t + t_1)] = e^{ist_1} g(s)$
7.  $F[f(t)] = G(i s) + G(-i s)$  if  $f(t) = f(-t)$  (f even)  
 $F[f(t)] = G(i s) - G(-i s)$  if  $f(t) = -f(-t)$  (f odd)

where  $G(s) = L[f(t)]$ . This result allows the use of the Laplace transform tables to obtain the Fourier transforms.

**Example 19.8.8.** Find  $F[e^{-at}]$  by property 7. The term  $e^{-at}$  is even. So  $L[e^{-at}] = 1/(s + a)$ . Therefore,  $F[e^{-at}] = 1/(i s + a) + 1/(-i s + a) = 2a/(s^2 + a^2)$ .

**Fourier Cosine Transform**

The *Fourier cosine transform* is given by  $F_c[f(t)] = g(s) = \sqrt{(2/\pi)} \int_0^\infty f(t) \cos s t dt$  and its *inverse* by  $F_c^{-1}[g(s)] = f(t) = \sqrt{(2/\pi)} \int_0^\infty g(s) \cos s t ds$ . The *Fourier sine transform*  $F_s$  is obtainable by replacing the cosine by the sine in the above integrals.

**Example 19.8.9.**  $F_c[f(t)], f(t) = 1$  for  $0 < t < a$  and  $0$  for  $a < t < \infty$ .  $F_c[f(t)] = \sqrt{(2/\pi)} \int_0^a \cos s t dt = \sqrt{(2/\pi)} (\sin a s)/s$ .

**Properties of the Fourier Cosine Transform**

$F_c[f(t)] = g(s)$ .

1.  $F_c[af(t) + bh(t)] = aF_c[f(t)] + bF_c[h(t)]$
2.  $F_c[f(at)] = (1/a) g(s/a)$
3.  $F_c[f(at) \cos bt] = 1/2a [g((s + b)/a) + g((s - b)/a)], a, b > 0$
4.  $F_c[t^{2n}f(t)] = (-1)^n (d^{2n}g)/(d s^{2n})$
5.  $F_c[t^{2n+1}f(t)] = (-1)^n (d^{2n+1}g)/(d s^{2n+1}) F_s[f(t)]$

Table 19.8.3 presents some Fourier cosine transforms.

**Example 19.8.10.** The temperature  $\theta$  in the semiinfinite rod  $0 \leq x < \infty$  is determined by the differential equation  $\partial\theta/\partial t = k(\partial^2\theta/\partial x^2)$  and the condition  $\theta = 0$  when  $t = 0, x \geq 0$ ;  $\partial\theta/\partial x = -\mu = \text{constant}$  when  $x = 0, t > 0$ . By using the Fourier cosine transform, a solution may be found as  $\theta(x, t) = (2\mu/\pi) \int_0^\infty (\cos px/p) (1 - e^{-kp^2t}) dp$ .

## 19.9 Calculus of Variations

William F. Ames

The basic problem in the *calculus of variations* is to determine a function such that a certain *functional*, often an integral involving that function and certain of its derivatives, takes on *maximum or minimum values*. As an example, find the function  $y(x)$  such that  $y(x_1) = y_1$ ,  $y(x_2) = y_2$  and the integral (functional)  $I = 2\pi \int_{x_1}^{x_2} y[1 + y'^2]^{1/2} dx$  is a minimum. A second example concerns the transverse deformation  $u(x, t)$  of a beam. The energy functional  $I = \int_{t_1}^{t_2} \int_0^L [1/2 \rho (\partial u/\partial t)^2 - 1/2 EI (\partial^2 u/\partial x^2)^2 + fu] dx dt$  is to be minimized.

### The Euler Equation

The elementary part of the theory is concerned with a *necessary* condition (generally in the form of a differential equation with boundary conditions) that the required function must satisfy. To show mathematically that the function obtained actually maximizes (or minimizes) the integral is much more difficult than the corresponding problems of the differential calculus.

The *simplest case* is to determine a function  $y(x)$  that makes the integral  $I = \int_{x_1}^{x_2} F(x, y, y') dx$  stationary and that satisfies the prescribed end conditions  $y(x_1) = y_1$  and  $y(x_2) = y_2$ . Here we suppose  $F$  has continuous second partial derivatives with respect to  $x, y$ , and  $y' = dy/dx$ . If  $y(x)$  is such a function, then it must satisfy the *Euler equation*  $(d/dx)(\partial F/\partial y') - (\partial F/\partial y) = 0$ , which is the required necessary condition. The indicated partial derivatives have been formed by treating  $x, y$ , and  $y'$  as independent variables. Expanding the equation, the equivalent form  $F_{y'y}y'' + F_{y'y'}y' + (F_{y'x} - F_y) = 0$  is found. This is second order in  $y$  unless  $F_{y'y} = (\partial^2 F)/[(\partial y')^2] = 0$ . An alternative form  $1/y'[d/dx(F - (\partial F/\partial y')(dy/dx)) - (\partial F/\partial x)] = 0$  is useful. Clearly, if  $F$  does not involve  $x$  explicitly  $[(\partial F/\partial x) = 0]$  a first integral of Euler's equation is  $F - y'(\partial F/\partial y') = c$ . If  $F$  does not involve  $y$  explicitly  $[(\partial F/\partial y) = 0]$  a first integral is  $(\partial F/\partial y') = c$ .

The Euler equation for  $I = 2\pi \int_{x_1}^{x_2} y[1 + (y')^2]^{1/2} dx$ ,  $y(x_1) = y_1$ ,  $y(x_2) = y_2$  is  $(d/dx)[yy'/[1 + (y')^2]^{1/2}] - [1 + (y')^2]^{1/2} = 0$  or after reduction  $yy'' - (y')^2 - 1 = 0$ . The solution is  $y = c_1 \cosh(x/c_1 + c_2)$ , where  $c_1$  and  $c_2$  are integration constants. Thus the required minimal surface, if it exists, must be obtained by revolving a catenary. Can  $c_1$  and  $c_2$  be chosen so that the solution passes through the assigned points? The answer is found in the solution of a transcendental equation that has two, one, or no solutions, depending on the prescribed values of  $y_1$  and  $y_2$ .

### The Variation

If  $F = F(x, y, y')$ , with  $x$  independent and  $y = y(x)$ , then the *first variation*  $\delta F$  of  $F$  is defined to be  $\delta F = (\partial F/\partial x) \delta x + (\partial F/\partial y) \delta y + (\partial F/\partial y') \delta y'$  and  $\delta y' = \delta (dy/dx) = (d/dx) (\delta y)$  — that is, they commute. Note that the first variation,  $\delta F$ , of a functional is a first-order change from curve to curve, whereas the differential of a function is a first-order approximation to the change in that function along a *particular curve*. The laws of  $\delta$  are as follows:  $\delta(c_1F + c_2G) = c_1\delta F + c_2\delta G$ ;  $\delta(FG) = F\delta G + G\delta F$ ;  $\delta(F/G) = (G\delta F - F\delta G)/G^2$ ; if  $x$  is an independent variable,  $\delta x = 0$ ; if  $u = u(x, y)$ ;  $(\partial/\partial x)(\delta u) = \delta(\partial u/\partial x)$ ,  $(\partial/\partial y) (\delta u) = \delta(\partial u/\partial y)$ .

A necessary condition that the integral  $I = \int_{x_1}^{x_2} F(x, y, y') dx$  be stationary is that its (first) variation vanish — that is,  $\delta I = \delta \int_{x_1}^{x_2} F(x, y, y') dx = 0$ . Carrying out the variation and integrating by parts yields of  $\delta I = \int_{x_1}^{x_2} [(\partial F/\partial y) - (d/dx)(\partial F/\partial y')] \delta y dx + [(\partial F/\partial y') \delta y]_{x_1}^{x_2} = 0$ . The arbitrary nature of  $\delta y$  means the square bracket must vanish and the last term constitutes the *natural boundary conditions*.

**Example.** The *Euler equation* of  $\int_{x_1}^{x_2} F(x, y, y', y'') dx$  is  $(d^2/dx^2)(\partial F/\partial y'') - (d/dx)(\partial F/\partial y') + (\partial F/\partial y) = 0$ , with natural boundary conditions  $\{[(d/dx)(\partial F/\partial y'') - (\partial F/\partial y')] \delta y\}_{x_1}^{x_2} = 0$  and  $(\partial F/\partial y'') \delta y'_{x_1}^{x_2} = 0$ . The Euler equation of  $\int_{x_1}^{x_2} \int_{y_1}^{y_2} F(x, y, u, u_x, u_y, u_{xx}, u_{xy}, u_{yy}) dx dy$  is  $(\partial^2/\partial x^2)(\partial F/\partial u_{xx}) + (\partial^2/\partial x \partial y)(\partial F/\partial u_{xy}) + (\partial^2/\partial y^2)(\partial F/\partial u_{yy}) - (\partial/\partial x)(\partial F/\partial u_x) - (\partial/\partial y)(\partial F/\partial u_y) + (\partial F/\partial u)$ , and the natural boundary conditions are

$$\left[ \left( \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial u_{xx}} \right) + \frac{\partial}{\partial y} \left( \frac{\partial F}{\partial u_{xy}} \right) - \frac{\partial F}{\partial u_x} \right) \delta u \right]_{x_1}^{x_2} = 0, \quad \left[ \left( \frac{\partial F}{\partial u_{xx}} \right) \delta u_x \right]_{x_1}^{x_2} = 0$$

$$\left[ \left( \frac{\partial}{\partial y} \left( \frac{\partial F}{\partial u_{yy}} \right) + \frac{\partial}{\partial x} \left( \frac{\partial F}{\partial u_{xy}} \right) - \frac{\partial F}{\partial u_y} \right) \delta u \right]_{y_1}^{y_2} = 0, \quad \left[ \left( \frac{\partial F}{\partial u_{yy}} \right) \delta u_y \right]_{y_1}^{y_2} = 0$$

In the more general case of  $I = \iint_R F(x, y, u, v, u_x, u_y, v_x, v_y) dx dy$ , the condition  $\delta I = 0$  gives rise to the two Euler equations  $(\partial/\partial x)(\partial F/\partial u_x) + (\partial/\partial y)(\partial F/\partial u_y) - (\partial F/\partial u) = 0$  and  $(\partial/\partial x)(\partial F/\partial v_x) + (\partial/\partial y)(\partial F/\partial v_y) - (\partial F/\partial v) = 0$ . These are two PDEs in  $u$  and  $v$  that are linear or quasi-linear in  $u$  and  $v$ . The Euler equation for  $I = \iiint_R (u_x^2 + u_y^2 + u_z^2) dx dy dz$ , from  $\delta I = 0$ , is Laplace's equation  $u_{xx} + u_{yy} + u_{zz} = 0$ .

Variational problems are easily derived from the differential equation and associated boundary conditions by multiplying by the variation and integrating the appropriate number of times. To illustrate, let  $F(x)$ ,  $\rho(x)$ ,  $p(x)$ , and  $w$  be the tension, the linear mass density, the natural load, and (constant) angular velocity of a rotating string of length  $L$ . The equation of motion is  $(d/dx)[F(dy/dx)] + \rho w^2 y + p = 0$ . To formulate a corresponding variational problem, multiply all terms by a variation  $\delta y$  and integrate over  $(0, L)$  to obtain

$$\int_0^L \frac{d}{dx} \left( F \frac{dy}{dx} \right) \delta y dx + \int_0^L \rho w^2 y \delta y dx + \int_0^L p \delta y dx = 0$$

The second and third integrals are the variations of  $1/2 \rho w^2 y^2$  and  $py$ , respectively. To treat the first integral, integrate by parts to obtain

$$\left[ F \frac{dy}{dx} \delta y \right]_0^L - \int_0^L F \frac{dy}{dx} \delta \frac{dy}{dx} dx = \left[ F \frac{dy}{dx} \delta y \right]_0^L - \int_0^L \frac{1}{2} F \delta \left( \frac{dy}{dx} \right)^2 dx = 0$$

So the variation formulation is

$$\delta \int_0^L \left[ \frac{1}{2} \rho w^2 y^2 + py - \frac{1}{2} F \left( \frac{dy}{dx} \right)^2 \right] dx + \left[ F \frac{dy}{dx} \delta y \right]_0^L = 0$$

The last term represents the *natural boundary conditions*. The term  $1/2 \rho w^2 y^2$  is the kinetic energy per unit length, the term  $-py$  is the potential energy per unit length due to the radial force  $p(x)$ , and the term  $1/2 F (dy/dx)^2$  is a first approximation to the potential energy per unit length due to the tension  $F(x)$  in the string. Thus the integral is often called the *energy integral*.

## Constraints

The variations in some cases cannot be arbitrarily assigned because of one or more auxiliary conditions that are usually called *constraints*. A typical case is the functional  $\int_{x_1}^{x_2} F(x, u, v, u_x, v_x) dx$  with a constraint  $\phi(u, v) = 0$  relating  $u$  and  $v$ . If the variations of  $u$  and  $v$  ( $\delta u$  and  $\delta v$ ) vanish at the end points, then the variation of the integral becomes

$$\int_{x_1}^{x_2} \left\{ \left[ \frac{\partial F}{\partial u} - \frac{d}{dx} \left( \frac{\partial F}{\partial u_x} \right) \right] \delta u + \left[ \frac{\partial F}{\partial v} - \frac{d}{dx} \left( \frac{\partial F}{\partial v_x} \right) \right] \delta v \right\} dx = 0$$

The variation of the constraint  $\phi(u, v) = 0$ ,  $\phi_u \delta u + \phi_v \delta v = 0$  means that the variations cannot both be assigned arbitrarily inside  $(x_1, x_2)$ , so their coefficients need not vanish separately. Multiply  $\phi_u \delta u + \phi_v \delta v = 0$  by a Lagrange multiplier  $\lambda$  (may be a function of  $x$ ) and integrate to find  $\int_{x_1}^{x_2} (\lambda \phi_u \delta u + \lambda \phi_v \delta v) dx = 0$ . Adding this to the previous result yields

$$\int_{x_1}^{x_2} \left\{ \left[ \frac{\partial F}{\partial u} - \frac{d}{dx} \left( \frac{\partial F}{\partial u_x} \right) + \lambda \phi_u \right] \delta u + \left[ \frac{\partial F}{\partial v} - \frac{d}{dx} \left( \frac{\partial F}{\partial v_x} \right) + \lambda \phi_v \right] \delta v \right\} dx = 0$$

which must hold for any  $\lambda$ . Assign  $\lambda$  so the first square bracket vanishes. Then  $\delta v$  can be assigned to vanish inside  $(x_1, x_2)$  so the two systems

$$\frac{d}{dx} \left[ \frac{\partial F}{\partial u_x} \right] - \frac{\partial F}{\partial u} - \lambda \phi_u = 0, \quad \frac{d}{dx} \left[ \frac{\partial F}{\partial v_x} \right] - \frac{\partial F}{\partial v} - \lambda \phi_v = 0$$

plus the constraint  $\phi(u, v) = 0$  are three equations for  $u$ ,  $v$  and  $\lambda$ .

## 19.10 Optimization Methods

George Cain

### Linear Programming

Let  $\mathbf{A}$  be an  $m \times n$  matrix,  $\mathbf{b}$  a column vector with  $m$  components, and  $\mathbf{c}$  a column vector with  $n$  components. Suppose  $m < n$ , and assume the rank of  $\mathbf{A}$  is  $m$ . The standard linear programming problem is to find, among all nonnegative solutions of  $\mathbf{Ax} = \mathbf{b}$ , one that minimizes

$$\mathbf{c}^T \mathbf{x} = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$$

This problem is called a *linear program*. Each solution of the system  $\mathbf{Ax} = \mathbf{b}$  is called a *feasible solution*, and the *feasible set* is the collection of all *feasible solutions*. The function  $\mathbf{c}^T \mathbf{x} = c_1 x_1 + c_2 x_2 + \cdots + c_n x_n$  is the cost function, or the objective function. A solution to the linear program is called an *optimal feasible solution*.

Let  $\mathbf{B}$  be an  $m \times n$  submatrix of  $\mathbf{A}$  made up of  $m$  linearly independent columns of  $\mathbf{A}$ , and let  $\mathbf{C}$  be the  $m \times (n - m)$  matrix made up of the remaining columns of  $\mathbf{A}$ . Let  $\mathbf{x}_B$  be the vector consisting of the components of  $\mathbf{x}$  corresponding to the columns of  $\mathbf{A}$  that make up  $\mathbf{B}$ , and let  $\mathbf{x}_C$  be the vector of the remaining components of  $\mathbf{x}$ , that is, the components of  $\mathbf{x}$  that correspond to the columns of  $\mathbf{C}$ . Then the equation  $\mathbf{Ax} = \mathbf{b}$  may be written  $\mathbf{Bx}_B + \mathbf{Cx}_C = \mathbf{b}$ . A solution of  $\mathbf{Bx}_B = \mathbf{b}$  together with  $\mathbf{x}_C = \mathbf{0}$  gives a solution  $\mathbf{x}$  of the system  $\mathbf{Ax} = \mathbf{b}$ . Such a solution is called a *basic solution*, and if it is, in addition, nonnegative, it is a *basic feasible solution*. If it is also optimal, it is an *optimal basic feasible solution*. The components of a basic solution are called *basic variables*.

The Fundamental Theorem of Linear Programming says that if there is a feasible solution, there is a basic feasible solution, and if there is an optimal feasible solution, there is an optimal basic feasible solution. The linear programming problem is thus reduced to searching among the set of basic solutions for an optimal solution. This set is, of course, finite, containing as many as  $n!/m!(n - m)!$  points. In practice, this will be a very large number, making it imperative that one use some efficient search procedure in seeking an optimal solution. The most important of such procedures is the *simplex method*, details of which may be found in the references.

The problem of finding a solution of  $\mathbf{Ax} \leq \mathbf{b}$  that minimizes  $\mathbf{c}^T \mathbf{x}$  can be reduced to the standard problem by appending to the vector  $\mathbf{x}$  an additional  $m$  nonnegative components, called *slack variables*. The vector  $\mathbf{x}$  is replaced by  $\mathbf{z}$ , where  $\mathbf{z}^T = [x_1, x_2, \dots, x_n, s_1, s_2, \dots, s_m]$ , and the matrix  $\mathbf{A}$  is replaced by  $\mathbf{B} = [\mathbf{A} \ \mathbf{I}]$ , where  $\mathbf{I}$  is the  $m \times m$  identity matrix. The equation  $\mathbf{Ax} = \mathbf{b}$  is thus replaced by  $\mathbf{Bz} = \mathbf{Ax} + \mathbf{s} = \mathbf{b}$ , where  $\mathbf{s}^T = [s_1, s_2, \dots, s_m]$ . Similarly, if inequalities are reversed so that we have  $\mathbf{Ax} \geq \mathbf{b}$ , we simply append  $-s$  to the vector  $\mathbf{x}$ . In this case, the additional variables are called *surplus variables*.

Associated with every linear programming problem is a corresponding dual problem. If the *primal* problem is to minimize  $\mathbf{c}^T \mathbf{x}$  subject to  $\mathbf{Ax} \geq \mathbf{b}$ , and  $\mathbf{x} \geq \mathbf{0}$ , the corresponding *dual* problem is to maximize  $\mathbf{y}^T \mathbf{b}$  subject to  $\mathbf{t}^T \mathbf{A} \leq \mathbf{c}^T$ . If either the primal problem or the dual problem has an optimal solution, so also does the other. Moreover, if  $\mathbf{x}_p$  is an optimal solution for the primal problem and  $\mathbf{y}_d$  is an optimal solution for the corresponding dual problem  $\mathbf{c}^T \mathbf{x}_p = \mathbf{y}_d^T \mathbf{b}$ .

### Unconstrained Nonlinear Programming

The problem of minimizing or maximizing a sufficiently smooth nonlinear function  $f(x)$  of  $n$  variables,  $\mathbf{x}^T = [x_1, x_2, \dots, x_n]$ , with no restrictions on  $\mathbf{x}$  is essentially an ordinary problem in calculus. At a minimizer or maximizer  $\mathbf{x}^*$ , it must be true that the gradient of  $f$  vanishes:

$$\nabla f(\mathbf{x}^*) = \mathbf{0}$$

Thus  $\mathbf{x}^*$  will be in the set of all solutions of this system of  $n$  generally nonlinear equations. The solution of the system can be, of course, a nontrivial undertaking. There are many recipes for solving systems of nonlinear equations. A method specifically designed for minimizing  $f$  is the *method of steepest descent*. It is an old and honorable algorithm, and the one on which most other more complicated algorithms for unconstrained optimization are based. The method is based on the fact that at any point  $\mathbf{x}$ , the direction of maximum decrease of  $f$  is in the direction of  $-\nabla f(\mathbf{x})$ . The algorithm searches in this direction for a minimum, recomputes  $\nabla f(\mathbf{x})$  at this point, and continues iteratively. Explicitly:

1. Choose an initial point  $\mathbf{x}_0$ .
2. Assume  $x_k$  has been computed; then compute  $y_k = \nabla f(x_k)$ , and let  $t_k \geq 0$  be a local minimum of  $g(t) = f(x_k - ty_k)$ . Then  $x_{k+1} = x_k - t_k y_k$ .
3. Replace  $k$  by  $k + 1$ , and repeat step 2 until  $t_k$  is small enough.

Under reasonably general conditions, the sequence  $(x_k)$  converges to a minimum of  $f$ .

### Constrained Nonlinear Programming

The problem of finding the maximum or minimum of a function  $f(x)$  of  $n$  variables, subject to the constraints

$$\mathbf{a}(\mathbf{x}) = \begin{bmatrix} a_1(x_1, x_2, \dots, x_n) \\ a_2(x_1, x_2, \dots, x_n) \\ \vdots \\ a_m(x_1, x_2, \dots, x_n) \end{bmatrix} = \begin{bmatrix} b_1 \\ b \\ \vdots \\ b_m \end{bmatrix} = \mathbf{b}$$

is made into an unconstrained problem by introducing the new function  $L(x)$ :

$$L(\mathbf{x}) = f(\mathbf{x}) + \mathbf{z}^T \mathbf{a}(\mathbf{x})$$

where  $\mathbf{z}^T = [\lambda_1, \lambda_2, \dots, \lambda_m]$  is the vector of *Lagrange multipliers*. Now the requirement that  $\nabla L(x) = 0$ , together with the constraints  $\mathbf{a}(\mathbf{x}) = \mathbf{b}$ , give a system of  $n + m$  equations

$$\begin{aligned} \nabla f(\mathbf{x}) + \mathbf{z}^T \nabla \mathbf{a}(\mathbf{x}) &= 0 \\ \mathbf{a}(\mathbf{x}) &= \mathbf{b} \end{aligned}$$

for the  $n + m$  unknowns  $x_1, x_2, \dots, x_n, \lambda_1, \lambda_2, \dots, \lambda_m$  that must be satisfied by the minimizer (or maximizer)  $\mathbf{x}$ .

The problem of inequality constraints is significantly more complicated in the nonlinear case than in the linear case. Consider the problem of minimizing  $f(x)$  subject to  $m$  equality constraints  $\mathbf{a}(\mathbf{x}) = \mathbf{b}$ , and  $p$  inequality constraints  $c(\mathbf{x}) \leq \mathbf{d}$  [thus  $\mathbf{a}(\mathbf{x})$  and  $\mathbf{b}$  are vectors of  $m$  components, and  $c(\mathbf{x})$  and  $\mathbf{d}$  are vectors of  $p$  components.] A point  $\mathbf{x}^*$  that satisfies the constraints is a *regular point* if the collection

$$\{\nabla a_1(\mathbf{x}^*), \nabla a_2(\mathbf{x}^*), \dots, \nabla a_m(\mathbf{x}^*)\} \cup \{\nabla c_j(\mathbf{x}^*) : j \in J\}$$

where

$$J = \{j : c_j(\mathbf{x}^*) = d_j\}$$

is linearly independent. If  $\mathbf{x}^*$  is a local minimum for the constrained problem and if it is a regular point, there is a vector  $\mathbf{z}$  with  $m$  components and a vector  $\mathbf{w} \geq \mathbf{0}$  with  $p$  components such that

$$\nabla f(\mathbf{x}^*) + \mathbf{z}^T \nabla \mathbf{a}(\mathbf{x}^*) + \mathbf{w}^T \nabla \mathbf{c}(\mathbf{x}^*) = \mathbf{0}$$

$$\mathbf{w}^T (\mathbf{c}(\mathbf{x}^*) - \mathbf{d}) = 0$$

These are the *Kuhn-Tucker conditions*. Note that in order to solve these equations, one needs to know for which  $j$  it is true that  $c_j(\mathbf{x}^*) = 0$ . (Such a constraint is said to be *active*.)

## 19.11 Engineering Statistics

*Y. L. Tong*

### Introduction

In most engineering experiments, the outcomes (and hence the observed data) appear in a random and on deterministic fashion. For example, the operating time of a system before failure, the tensile strength of a certain type of material, and the number of defective items in a batch of items produced are all subject to random variations from one experiment to another. In engineering statistics, we apply the theory and methods of statistics to develop procedures for summarizing the data and making statistical inferences, thus obtaining useful information with the presence of randomness and uncertainty.

### Elementary Probability

#### Random Variables and Probability Distributions

Intuitively speaking, a random variable (denoted by  $X, Y, Z$ , etc.) takes a numerical value that depends on the outcome of the experiment. Since the outcome of an experiment is subject to random variation, the resulting numerical value is also random. In order to provide a stochastic model for describing the probability distribution of a random variable  $X$ , we generally classify random variables into two groups: the discrete type and the continuous type. The discrete random variables are those which, technically speaking, take a finite number or a countably infinite number of possible numerical values. (In most engineering applications they take nonnegative integer values.) Continuous random variables involve outcome variables such as time, length or distance, area, and volume. We specify a function  $f(x)$ , called the probability density function (p.d.f.) of a random variable  $X$ , such that the random variable  $X$  takes a value in a set  $A$  (or real numbers) as given by

$$P[X \in A] = \begin{cases} \sum_{x \in A} f(x) & \text{for all sets } A \text{ if } X \text{ is discrete} \\ \int_A f(x) dx & \text{for all intervals } A \text{ if } X \text{ is continuous} \end{cases} \quad (9.11.1)$$

By letting  $A$  be the set of all values that are less than or equal to a fixed number  $t$ , i.e.,  $A = (-\infty, t]$ , the probability function  $P[X \leq t]$ , denoted by  $F(t)$ , is called the distribution function of  $X$ . We note that, by calculus, if  $X$  is a continuous random variable and if  $F(x)$  is differentiable, then  $f(x) = \frac{d}{dx} F(x)$ .

#### Expectations

In many applications the “payoff” or “reward” of an experiment with a numerical outcome  $X$  is a specific function of  $X$  ( $u(X)$ , say). Since  $X$  is a random variable,  $u(X)$  is also a random variable. We define the expected value of  $u(X)$  by

$$Eu(X) = \begin{cases} \sum_x u(x) f(x) & \text{if } X \text{ is discrete} \\ \int_{-\infty}^{\infty} u(x) f(x) dx & \text{if } X \text{ is continuous} \end{cases} \quad (9.11.12)$$

provided of course, that, the sum or the integral exists. In particular, if  $u(x) = x$ , the  $EX \equiv \mu$  is called the mean of  $X$  (of the distribution) and  $E(X - \mu)^2 \equiv \sigma^2$  is called the variance of  $X$  (of the distribution). The mean is a measurement of the central tendency, and the variance is a measurement of the dispersion of the distribution.

### Some Commonly Used Distributions

Many well-known distributions are useful in engineering statistics. Among the discrete distributions, the hypergeometric and binomial distributions have applications in acceptance sampling problems and quality control, and the Poisson distribution is useful for studying queuing theory and other related problems. Among the continuous distributions, the uniform distribution concerns random numbers and can be applied in simulation studies, the exponential and gamma distributions are closely related to the Poisson distribution, and they, together with the Weibull distribution, have important applications in life testing and reliability studies. All of these distributions involve some unknown parameter(s), hence their means and variances also depend on the parameter(s). The reader is referred to textbooks in this area for details. For example, Hahn and Shapiro (1967, pp. 163–169 and pp. 120–134) contains a comprehensive listing of these and other distributions on their p.d.f.'s and the graphs, parameter(s), means, variances, with discussions and examples of their applications.

### The Normal Distribution

Perhaps *the* most important distribution in statistics and probability is the normal distribution (also known as the Gaussian distribution). This distribution involves two parameters:  $\mu$  and  $\sigma^2$ , and its p.d.f. is given by

$$f(x) = f(x; \mu, \sigma^2) = \frac{1}{\sqrt{2\pi}\sigma} e^{-\frac{1}{2\sigma^2}(x-\mu)^2} \quad (9.11.3)$$

for  $-\infty < \mu < \infty$ ,  $\sigma^2 > 0$ , and  $-\infty < x < \infty$ . It can be shown analytically that, for a p.d.f. of this form, the values of  $\mu$  and  $\sigma^2$  are, respectively, that of the mean and the variance of the distribution. Further, the quantity,  $\sigma = \sqrt{\sigma^2}$  is called the standard deviation of the distribution. We shall use the symbol  $X \sim N(\mu, \sigma^2)$  to denote that  $X$  has a normal distribution with mean  $\mu$  and variance  $\sigma^2$ . When plotting the p.d.f.  $f(x; \mu, \sigma^2)$  given in Equation (19.11.3) we see that the resulting graph represents a bell-shaped curve symmetric about  $\mu$ , as shown in Figure 19.11.1.

**FIGURE 19.11.1** The normal curve with mean  $\mu$  and variance  $\sigma^2$ .

If a random variable  $Z$  has an  $N(0,1)$  distribution, then the p.d.f. of  $Z$  is given by (from Equation (19.11.3))

$$\phi(z) = \frac{1}{\sqrt{2\pi}} e^{-\frac{1}{2}z^2} \quad -\infty < z < \infty \quad (9.11.4)$$

The distribution function of  $Z$ ,

$$\Phi(z) = \int_{-\infty}^z \phi(u) du \quad -\infty < z < \infty \quad (9.11.5)$$

cannot be given in a closed form, hence it has been tabulated. The table of  $\Phi(z)$  can be found in most textbooks in statistics and probability, including those listed in the references at the end of this section. (We note in passing that, by the symmetry property,  $\Phi(z) + \Phi(-z) = 1$  holds for all  $z$ .)

## Random Sample and Sampling Distributions

### Random Sample and Related Statistics

As noted in Box et al., (1978), the design and analysis of engineering experiments usually involves the following steps:

1. The choice of a suitable stochastic model by assuming that the observations follow a certain distribution. The functional form of the distribution (or the p.d.f.) is assumed to be known, except the value(s) of the parameter(s).
2. Design of experiments and collection of data.
3. Summarization of data and computation of certain statistics.
4. Statistical inference (including the estimation of the parameters of the underlying distribution and the hypothesis-testing problems).

In order to make statistical inference concerning the parameter(s) of a distribution, it is essential to first study the sampling distributions. We say that  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  if they are independent random variables and each of them has the same p.d.f.,  $f(x)$ . (Due to space limitations, the notion of independence will not be carefully discussed here. Nevertheless, we say that  $X_1, X_2, \dots, X_n$  are independent if

$$P[X_1 \in A_1, X_2 \in A_2, \dots, X_n \in A_n] = \prod_{i=1}^n P[X_i \in A_i] \tag{19.11.6}$$

holds for all sets  $A_1, A_2, \dots, A_n$ .) Since the parameter(s) of the population is (are) unknown, the population mean  $\mu$  and the population variance  $\sigma^2$  are unknown. In most commonly used distributions  $\mu$  and  $\sigma^2$  can be estimated by the sample mean  $\bar{X}$  and the sample variance  $S^2$ , respectively, which are given by

$$\bar{X} = \frac{1}{n} \sum_{i=1}^n X_i, \quad S^2 = \frac{1}{n-1} \sum_{i=1}^n (X_i - \bar{X})^2 = \frac{1}{n-1} \left[ \sum_{i=1}^n X_i^2 - n\bar{X}^2 \right] \tag{19.11.7}$$

(The second equality in the formula for  $S^2$  can be verified algebraically.) Now, since  $X_1, X_2, \dots, X_n$  are random variables  $\bar{X}$  and  $S^2$  are also random variables. Each of them is called a statistic and has a probability distribution which also involves the unknown parameter(s). In probability theory there are two fundamental results concerning their distributional properties.

*Theorem 1.* (Weak Law of Large Numbers). As the sample size  $n$  becomes large,  $\bar{X}$  converges to  $\mu$  in probability and  $S^2$  converges to  $\sigma^2$  in probability. More precisely, for every fixed positive number  $\epsilon > 0$  we have

$$P[|\bar{X} - \mu| \leq \epsilon] \rightarrow 1, \quad P[|S^2 - \sigma^2| \leq \epsilon] \rightarrow 1 \tag{19.11.8}$$

as  $n \rightarrow \infty$ .

*Theorem 2.* (Central Limit Theorem). As  $n$  becomes large, the distribution of the random variable

$$Z = \frac{\bar{X} - \mu}{\sigma / \sqrt{n}} = \frac{\sqrt{n}(\bar{X} - \mu)}{\sigma} \tag{19.11.9}$$

has approximately an  $N(0,1)$  distribution. More precisely,

$$P[Z \leq z] \rightarrow \Phi(z) \text{ for every fixed } z \text{ as } n \rightarrow \infty \tag{19.11.10}$$

## Normal Distribution-Related Sampling Distributions

### One-Sample Case

Additional results exist when the observations come from a normal population. If  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  from an  $N(\mu, \sigma^2)$  population, then the following sample distributions are useful:

*Fact 3.* For every fixed  $n$  the distribution of  $Z$  given in Equation (19.11.9) has *exactly* an  $N(0,1)$  distribution.

*Fact 4.* The distribution of the statistic  $T = \sqrt{n}(\bar{X} - \mu)/S$ , where  $S = \sqrt{S^2}$  is the sample standard deviation, is called a *Student's t distribution* with  $\nu = n - 1$  degrees of freedom, in symbols,  $t(n - 1)$ .

This distribution is useful for making inference on  $\mu$  when  $\sigma^2$  is unknown; a table of the percentiles can be found in most statistics textbooks.

*Fact 5.* The distribution of the statistic  $W = (n - 1)S^2/\sigma^2$  is called a *chi-squared distribution* with  $\nu = n - 1$  degrees of freedom, in symbols  $\chi^2(\nu)$ .

Such a distribution is useful in making inference on  $\sigma^2$ ; a table of the percentiles can also be found in most statistics books.

### Two-Sample Case

In certain applications we may be interested in the comparisons of two different treatments. Suppose that independent samples from treatments  $T_1$  and  $T_2$  are to be observed as shown in [Table 19.11.1](#).

**TABLE 19.11.1 Summarization of Data for a Two-Sample Problem**

Treatment	Observations	Distribution	Sample Size	Sample Mean	Sample Variance
$T_1$	$X_{11}, X_{12}, \dots, X_{1n_1}$	$\mathcal{N}(\mu_1, \sigma_1^2)$	$n_1$	$\bar{X}_1$	$S_1^2$
$T_2$	$X_{21}, X_{22}, \dots, X_{2n_2}$	$\mathcal{N}(\mu_2, \sigma_2^2)$	$n_2$	$\bar{X}_2$	$S_2^2$

The difference of the population means  $(\mu_1 - \mu_2)$  and the ratio of the population variances can be estimated, respectively, by  $(\bar{X}_1 - \bar{X}_2)$  and  $S_1^2/S_2^2$ . The following facts summarize the distributions of these statistics:

*Fact 6.* Under the assumption of normality,  $(\bar{X}_1 - \bar{X}_2)$  has an  $N(\mu_1 - \mu_2, (\sigma_1^2/n_1) + (\sigma_2^2/n_2))$  distribution; or equivalently, for all  $n_1, n_2$  the statistic

$$Z = \left[ (\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2) \right] / \left( \sigma_1^2/n_1 + \sigma_2^2/n_2 \right)^{1/2} \tag{19.11.11}$$

has an  $N(0,1)$  distribution.

*Fact 7.* When  $\sigma_1^2 = \sigma_2^2 \equiv \sigma^2$ , the common population variance is estimated by

$$S_p^2 = (n_1 + n_2 - 2)^{-1} \left[ (n_1 - 1)S_1^2 + (n_2 - 1)S_2^2 \right] \tag{19.11.12}$$

and  $(n_1 + n_2 - 2)S_p^2/\sigma^2$  has a  $\chi^2(n_1 + n_2 - 2)$  distribution.

*Fact 8.* When  $\sigma_1^2 = \sigma_2^2$ , the statistic

$$T = \left[ (\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2) \right] / S_p (1/n_1 + 1/n_2)^{1/2} \tag{19.11.13}$$

has a  $t(n_1 + n_2 - 2)$  distribution, where  $S_p = \sqrt{S_p^2}$ .

*Fact 9.* The distribution of  $F = (S_1^2/\sigma_1^2)/(S_2^2/\sigma_2^2)$  is called an F distribution with degrees of freedom  $(n_1 - 1, n_2 - 1)$ , in symbols,  $F(n_1 - 1, n_2 - 1)$ ,

The percentiles of this distribution have also been tabulated and can be found in statistics books.

In the following two examples we illustrate numerically how to find probabilities and percentiles using the existing tables for the normal, Student's  $t$ , chi-squared, and  $F$  distributions.

*Example 10.* Suppose that in an experiment four observations are taken, and that the population is assumed to have a normal distribution with mean  $\mu$  and variance  $\sigma^2$ . Let  $\bar{X}$  and  $S^2$  be the sample mean and sample variance as given in Equation (19.11.7).

(a) If, based on certain similar experiments conducted in the past, we know that  $\sigma^2 = 1.8^2 \times 10^{-6}$  ( $\sigma = 1.8 \times 10^{-3}$ ), then from  $\Phi(-1.645) = 0.05$  and  $\Phi(1.96) = 0.975$  we have

$$P \left[ -1.645 \leq \frac{\bar{X} - \mu}{1.8 \times 10^{-3} \sqrt{4}} \leq 1.96 \right] = 0.975 - 0.05 = 0.925$$

or equivalently,

$$P \left[ -1.645 \times 0.9 \times 10^{-3} \leq \bar{X} - \mu \leq 1.96 \times 0.9 \times 10^{-3} \right] = 0.925$$

(b) The statistic  $T = 2(\bar{X} - \mu)/S$  has a Student's  $t$  distribution with 3 degrees of freedom (in symbols,  $t(3)$ ). From the  $t$  table we have

$$P \left[ -3.182 \leq 2(\bar{X} - \mu)/S \leq 3.182 \right] = 0.95$$

which yields

$$P \left[ -3.182 \times \frac{S}{2} \leq \bar{X} - \mu \leq 3.182 \times \frac{S}{2} \right] = 0.95$$

or equivalently,

$$P \left[ \bar{X} - 3.182 \times \frac{S}{2} \leq \mu \leq \bar{X} + 3.182 \times \frac{S}{2} \right] = 0.95$$

This is, in fact, the basis for obtaining the confidence interval for  $\mu$  given in Equation (19.11.17) when  $\sigma^2$  is unknown.

(c) The statistic  $3S^2/\sigma^2$  has a chi-squared distribution with 3 degrees of freedom (in symbols,  $\chi^2(3)$ ). Thus from the chi-squared table we have  $P[0.216 \leq 3S^2/\sigma^2 \leq 9.348] = 0.95$ , which yields

$$P \left[ \frac{3S^2}{9.348} \leq \sigma^2 \leq \frac{3S^2}{0.216} \right] = 0.95$$

and it forms the basis for obtaining a confidence interval for  $\sigma^2$  as given in Equation (19.11.18).

*Example 11.* Suppose that in Table 19.11.1 (with two treatments) we have  $n_1 = 4$  and  $n_2 = 5$ , and we let  $\bar{X}_1, \bar{X}_2$  and  $S_1^2, S_2^2$  denote the corresponding sample means and sample variances, respectively.

(a) Assume that  $\sigma_1^2 = \sigma_2^2$  where the common variance is unknown and is estimated by  $S_p^2$  given in Equation (19.11.12). Then the statistic

$$T = \left[ (\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2) \right] / S_p \left( \frac{1}{4} + \frac{1}{5} \right)^{1/2}$$

has a  $t(7)$  distribution. Thus from the  $t$  table we have

$$P = \left[ -2.998 \leq \left[ (\bar{X}_1 - \bar{X}_2) - (\mu_1 - \mu_2) \right] / S_p \left( \frac{1}{4} + \frac{1}{5} \right)^{1/2} \leq 2.998 \right] = 0.98$$

which is equivalent to saying that

$$P \left[ -2.998 S_p \left( \frac{1}{4} + \frac{1}{5} \right)^{1/2} \leq \mu_1 - \mu_2 \leq (\bar{X}_1 - \bar{X}_2) + 2.998 S_p \left( \frac{1}{4} + \frac{1}{5} \right)^{1/2} \right] = 0.98$$

(b) The statistic  $F = (S_1^2 / \sigma_1^2) / (S_2^2 / \sigma_2^2)$  has an  $F(3,4)$  distribution. Thus from the  $F$ -table we have

$$P \left[ \left( \frac{\sigma_2^2}{\sigma_1^2} \right) \left( \frac{S_1^2}{S_2^2} \right) \leq 6.59 \right] = 0.95$$

or equivalently,

$$P \left[ \frac{\sigma_2^2}{\sigma_1^2} \leq 6.59 \frac{S_2^2}{S_1^2} \right] = 0.95$$

The distributions listed above (normal, Student's  $t$ , chi-squared, and  $F$ ) form an integral part of the classical statistical inference theory, and they are developed under the assumption that the observations follow a normal distribution. When the distribution of the population is not normal and inference on the populations means is to be made, we conclude that (1) if the sample sizes  $n_1, n_2$  are large, then the statistic  $Z$  in Equation (19.11.11) has an approximate  $N(0,1)$  distribution and (2) in the small-sample case, the exact distribution of  $\bar{X}$  (of  $(\bar{X}_1 - \bar{X}_2)$ ) depends on the population p.d.f. There are several analytical methods for obtaining it, and those methods can be found in statistics textbooks.

## Confidence Intervals

A method for estimating the population parameters based on the sample mean(s) and sample variance(s) involves the confidence intervals for the parameters.

### One-Sample Case

*1. Confidence Interval for  $\mu$  When  $\sigma^2$  is Known.* Consider the situation in which a random sample of size  $n$  is taken from an  $N(\mu, \sigma^2)$  population and  $\sigma^2$  is known. An interval,  $I_1$ , of the form  $I_1 = (\bar{X} - d, \bar{X} + d)$  (with width  $2d$ ) is to be constructed as a "confidence interval or  $\mu$ ." If we make the assertion that  $\mu$  is in this interval (i.e.,  $\mu$  is bounded below by  $\bar{X} - d$  and bounded above by  $\bar{X} + d$ ), then sometimes this assertion is correct and sometimes it is wrong, depending on the value of  $\bar{X}$  in a given experiment. If for a fixed  $\alpha$  value we would like to have a confidence probability (called confidence coefficient) such that

$$P[\mu \in I_1] = P[\bar{X} - d < \mu < \bar{X} + d] = 1 - \alpha \tag{19.11.14}$$

then we need to choose the value of  $d$  to satisfy  $d = z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$ , i.e.,

$$I_1 = \left( \bar{X} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}}, \bar{X} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right) \tag{19.11.15}$$

where  $z_{\alpha/2}$  is the  $(1 - \alpha/2)$ th percentile of the  $N(0,1)$  distribution such that  $\Phi(z_{\alpha/2}) = 1 - \alpha/2$ . To see this, we note that from the sampling distribution of  $\bar{X}$  (Fact 3) we have

$$\begin{aligned} P\left[ \bar{X} - z_{\alpha/2} \frac{\sigma}{\sqrt{n}} < \mu < \bar{X} + z_{\alpha/2} \frac{\sigma}{\sqrt{n}} \right] &= P\left[ \frac{|\bar{X} - \mu|}{\frac{\sigma}{\sqrt{n}}} \leq z_{\alpha/2} \right] \\ &= \Phi(z_{\alpha/2}) - \Phi(-z_{\alpha/2}) = 1 - \alpha \end{aligned} \tag{19.11.16}$$

We further note that, even when the original population is not normal, by Theorem 2 the confidence probability is approximately  $(1 - \alpha)$  when the sample size is reasonably large.

**2. Confidence Interval for  $\mu$  When  $\sigma^2$  is Unknown.** Assume that the observations are from an  $N(\mu, \sigma^2)$  population. When  $\sigma^2$  is unknown, by Fact 4 and a similar argument we see that

$$I_2 = \left( \bar{X} - t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}}, \bar{X} + t_{\alpha/2}(n-1) \frac{S}{\sqrt{n}} \right) \tag{19.11.17}$$

is a confidence interval for  $\mu$  with confidence probability  $1 - \alpha$ , where  $t_{\alpha/2}(n - 1)$  is the  $(1 - \alpha/2)$ th percentile of the  $t(n - 1)$  distribution.

**3. Confidence Interval for  $\sigma^2$ .** If, under the same assumption of normality, a confidence interval for  $\sigma^2$  is needed when  $\mu$  is unknown, then

$$I_3 = \left( (n-1)S^2 / \chi^2_{1-\alpha/2}(n-1), (n-1)S^2 / \chi^2_{\alpha/2}(n-1) \right) \tag{19.11.18}$$

has a confidence probability  $1 - \alpha$ , when  $\chi^2_{1-\alpha/2}(n - 1)$  and  $\chi^2_{\alpha/2}(n - 1)$  are the  $(\alpha/2)$ th and  $(1 - \alpha/2)$ th percentiles, respectively, of the  $\chi^2(n - 1)$  distribution.

**Two-Sample Case**

**1. Confidence Intervals for  $\mu_1 - \mu_2$  When  $\sigma_1^2 = \sigma_2^2$  are Known.** Consider an experiment that involves the comparison of two treatments,  $T_1$  and  $T_2$ , as indicated in Table 19.11.1. If a confidence interval for  $\delta = \mu_1 - \mu_2$  is needed when  $\sigma_1^2$  and  $\sigma_2^2$  are unknown, then by Fact 6 and a similar argument, the confidence interval

$$I_4 = \left( (\bar{X}_1 - \bar{X}_2) - z_{\alpha/2} \sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2}, (\bar{X}_1 - \bar{X}_2) + z_{\alpha/2} \sqrt{\sigma_1^2/n_1 + \sigma_2^2/n_2} \right) \tag{19.11.19}$$

has a confidence probability  $1 - \alpha$ .

**2. Confidence Interval for  $\mu_1 - \mu_2$  when  $\sigma_1^2, \sigma_2^2$  are Unknown but Equal.** Under the additional assumption that  $\sigma_1^2 = \sigma_2^2$ , but the common variance is unknown, then by Fact 8 the confidence interval

$$I_5 = \left( (\bar{X}_1 - \bar{X}_2) - d, (\bar{X}_1 - \bar{X}_2) + d \right) \quad (19.11.20)$$

has a confidence probability  $1 - \alpha$ , where

$$d = t_{\alpha/2}(n_1 + n_2 - 2) S_p (1/n_1 + 1/n_2)^{1/2} \quad (19.11.21)$$

3. *Confidence Interval for  $\sigma_2^2/\sigma_1^2$ .* A confidence interval for the ratio of the variances  $\sigma_2^2/\sigma_1^2$  can be obtained from the  $F$  distribution (see Fact 9), and the confidence interval

$$I_6 = \left( F_{1-\alpha/2}(n_1 - 1, n_2 - 1) \frac{S_2^2}{S_1^2}, F_{\alpha/2}(n_1 - 1, n_2 - 1) \frac{S_2^2}{S_1^2} \right) \quad (19.11.22)$$

has a confidence probability  $1 - \alpha$ , where  $F_{1-\alpha/2}(n_1 - 1, n_2 - 1)$  and  $F_{\alpha/2}(n_1 - 1, n_2 - 1)$  are, respectively, the  $(\alpha/2)$ th and  $(1 - \alpha/2)$ th percentiles of the  $F(n_1 - 1, n_2 - 1)$  distribution.

## Testing Statistical Hypotheses

A statistical hypothesis concerns a statement or assertion about the true value of the parameter in a given distribution. In the two-hypothesis problems, we deal with a null hypothesis and an alternative hypothesis, denoted by  $H_0$  and  $H_1$ , respectively. A decision is to be made, based on the data of the experiment, to either accept  $H_0$  (hence reject  $H_1$ ) or reject  $H_0$  (hence accept  $H_1$ ). In such a two-action problem, we may commit two types of errors: the type I error is to reject  $H_0$  when it is true, and the type II error is to accept  $H_0$  when it is false. As a standard practice, we do not reject  $H_0$  unless there is significant evidence indicating that it may be false. (In doing so, the burden of proof that  $H_0$  is false is on the experimenter.) Thus we usually choose a small fixed number,  $\alpha$  (such as 0.05 or 0.01), such that the probability of committing a type I error is at most (or equal to)  $\alpha$ . With such a given  $\alpha$ , we can then determine the region in the data space for the rejection of  $H_0$  (called the critical region).

### One-Sample Case

Suppose that  $X_1, X_2, \dots, X_n$  represent a random sample of size  $n$  from an  $N(\mu, \sigma^2)$  population, and  $\bar{X}$  and  $S^2$  are, respectively, the sample mean and sample variance.

1. *Test for Mean.* In testing

$$H_0 : \mu = \mu_0 \text{ vs. } H_1 : \mu = \mu_1 (\mu_1 > \mu_0) \text{ or } H_1 : \mu > \mu_0$$

when  $\sigma^2$  is known, we reject  $H_0$  when  $\bar{X}$  is large. To determine the cut-off point, we note (by Fact 3) that the statistic  $Z_0 = (\bar{X} - \mu_0)/(\sigma/\sqrt{n})$  has an  $N(0,1)$  distribution under  $H_0$ . Thus, if we decide to reject  $H_0$  when  $Z_0 > z_\alpha$ , then the probability of committing a type I error is  $\alpha$ . As a consequence, we apply the decision rule

$$d_1 : \text{reject } H_0 \text{ if and only if } \bar{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}$$

Similarly, from the distribution of  $Z_0$  under  $H_0$  we can obtain the critical region for the other types of hypotheses. When  $\sigma^2$  is unknown, then by Fact 4  $T_0 = \sqrt{n}(\bar{X} - \mu_0)/S$  has a  $t(n - 1)$  distribution under  $H_0$ . Thus the corresponding tests can be obtained by substituting  $t_\alpha(n - 1)$  for  $z_\alpha$  and  $S$  for  $\sigma$ . The tests for the various one-sided and two-sided hypotheses are summarized in [Table 19.11.2](#) below. For each set of hypotheses, the critical region given on the first line is for the case when  $\sigma^2$  is known, and that

**TABLE 19.11.2 One-Sample Tests for Mean**

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\mu = \mu_0$ or $\mu \leq \mu_0$	$\mu = \mu_1 > \mu_0$ or $\mu > \mu_0$	$\bar{X} > \mu_0 + z_\alpha \frac{\sigma}{\sqrt{n}}$ $\bar{X} > \mu_0 + t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$ or $\mu \geq \mu_0$	$\mu = \mu_1 < \mu_0$ or $\mu < \mu_0$	$\bar{X} < \mu_0 - z_\alpha \frac{\sigma}{\sqrt{n}}$ $\bar{X} < \mu_0 - t_\alpha \frac{S}{\sqrt{n}}$
$\mu = \mu_0$	$\mu \neq \mu_0$	$ \bar{X} - \mu_0  > z_{\alpha/2} \frac{\sigma}{\sqrt{n}}$ $ \bar{X} - \mu_0  > t_{\alpha/2} \frac{S}{\sqrt{n}}$

given on the second line is for the case when  $\sigma^2$  is unknown. Furthermore,  $t_\alpha$  and  $t_{\alpha/2}$  stand for  $t_\alpha(n - 1)$  and  $t_{\alpha/2}(n - 1)$ , respectively.

2. *Test for Variance.* In testing hypotheses concerning the variance  $\sigma^2$  of a normal distribution, use Fact 5 to assert that, under  $H_0: \sigma^2 = \sigma_0^2$ , the distribution of  $w_0 = (n - 1) S^2 / \sigma_0^2$  is  $\chi^2(n - 1)$ . The corresponding tests and critical regions are summarized in the following table ( $\chi_\alpha^2$  and  $\chi_{\alpha/2}^2$  stand for  $\chi_\alpha^2(n - 1)$  and  $\chi_{\alpha/2}^2(n - 1)$ , respectively):

**TABLE 19.11.3 One-Sample Tests for Variance**

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \leq \sigma_0^2$	$\sigma^2 = \sigma_1^2 > \sigma_0^2$ or $\sigma^2 > \sigma_0^2$	$(S^2 / \sigma_0^2) > \frac{1}{n-1} \chi_\alpha^2$
$\sigma^2 = \sigma_0^2$ or $\sigma^2 \geq \sigma_0^2$	$\sigma^2 = \sigma_1^2 < \sigma_0^2$ or $\sigma^2 < \sigma_0^2$	$(S^2 / \sigma_0^2) < \frac{1}{n-1} \chi_{1-\alpha}^2$
$\sigma^2 = \sigma_0^2$	$\sigma^2 \neq \sigma_0^2$	$(S^2 / \sigma_0^2) > \frac{1}{n-1} \chi_{\alpha/2}^2$ or $(S^2 / \sigma_0^2) < \frac{1}{n-1} \chi_{1-\alpha/2}^2$

**Two-Sample Case**

In comparing the means and variances of two normal populations, we once again refer to [Table 19.11.1](#) for notation and assumptions.

1. *Test for Difference of Two Means.* Let  $\delta = \mu_1 - \mu_2$  be the difference of the two population means. In testing  $H_0: \delta = \delta_0$  vs. a one-sided or two-sided alternative hypothesis, we note that, for

$$\tau = \left( \sigma_1^2 / n_1 + \sigma_2^2 / n_2 \right)^{1/2} \tag{19.11.23}$$

and

$$v = S_p \left( 1/n_1 + 1/n_2 \right)^{1/2} \tag{19.11.24}$$

$Z_0 = [(\bar{X}_1 - \bar{X}_2) - \delta_0]/\tau$  has an  $N(0,1)$  distribution under  $H_0$  and  $T_0 = [(\bar{X}_1 - \bar{X}_2) - \delta_0]/\nu$  has a  $t(n_1 + n_2 - 2)$  distribution under  $H_0$  when  $\sigma_1^2 = \sigma_2^2$ . Using these results, the corresponding critical regions for one-sided and two-sided tests can be obtained, and they are listed below. Note that, as in the one-sample case, the critical region given on the first line for each set of hypotheses is for the case of known variances, and that given on the second line is for the case in which the variances are equal but unknown. Further,  $t_\alpha$  and  $t_{\alpha/2}$  stand for  $t_\alpha(n_1 + n_2 - 2)$  and  $t_{\alpha/2}(n_1 + n_2 - 2)$ , respectively.

**TABLE 19.11.4 Two-Sample Tests for Difference of Two Means**

Null Hypothesis $H_0$	Alternative Hypothesis $H_1$	Critical Region
$\delta = \delta_0$ or $\delta \leq \delta_0$	$\delta = \delta_1 > \delta_0$ or $\delta > \delta_0$	$(\bar{X}_1 - \bar{X}_2) > \delta_0 + z_\alpha \tau$ $(\bar{X}_1 - \bar{X}_2) > \delta_0 + t_\alpha \nu$
$\delta = \delta_0$ or $\delta \geq \delta_0$	$\delta = \delta_1 < \delta_0$ or $\delta < \delta_0$	$(\bar{X}_1 - \bar{X}_2) < \delta_0 - z_\alpha \tau$ $(\bar{X}_1 - \bar{X}_2) < \delta_0 - t_\alpha \nu$
$\delta = \delta_0$	$\delta \neq \delta_0$	$ (\bar{X}_1 - \bar{X}_2) - \delta_0  > z_{\alpha/2} \tau$ $ (\bar{X}_1 - \bar{X}_2) - \delta_0  > t_{\alpha/2} \nu$

### A Numerical Example

In the following we provide a numerical example for illustrating the construction of confidence intervals and hypothesis-testing procedures. The example is given along the line of applications in Wadsworth (1990, p. 4.21) with artificial data.

Suppose that two processes ( $T_1$  and  $T_2$ ) manufacturing steel pins are in operation, and that a random sample of 4 pins (or 5 pins) was taken from the process  $T_1$  (the process  $T_2$ ) with the following results (in units of inches):

$$T_1 : 0.7608, 0.7596, 0.7622, 0.7638$$

$$T_2 : 0.7546, 0.7561, 0.7526, 0.7572, 0.7565$$

Simple calculation shows that the observed values of sample means sample variances, and sample standard deviations are:

$$\bar{X}_1 = 0.7616, \quad S_1^2 = 3.280 \times 10^{-6}, \quad S_1 = 1.811 \times 10^{-3}$$

$$\bar{X}_2 = 0.7554, \quad S_2^2 = 3.355 \times 10^{-6}, \quad S_2 = 1.832 \times 10^{-3}$$

### One-Sample Case

Let us first consider confidence intervals for the parameters of the first process,  $T_1$ , only.

1. Assume that, based on previous knowledge of processes of this type, the variance is known to be  $\sigma_1^2 = 1.80^2 \times 10^{-6}$  ( $\sigma_1 = 0.0018$ ). Then from the normal table (see, e.g., Ross (1987, p. 482) we have  $z_{0.025} = 1.96$ . Thus a 95% confidence interval for  $\mu_1$  is

$$(0.7616 - 1.96 \times 0.0018/\sqrt{4}, 0.7616 + 1.96 \times 0.0018/\sqrt{4})$$

or (0.7598, 0.7634) (after rounding off to the 4th decimal place).

- If  $\sigma_1^2$  is unknown and a 95% confidence interval for  $\mu_1$  is needed then, for  $t_{0.025}(3) = 3.182$  (see, e.g., Ross, 1987, p. 484) the confidence interval is

$$\left(0.7616 - 3.182 \times 0.001811/\sqrt{4}, 0.7616 + 3.182 \times 0.001811/\sqrt{4}\right)$$

or (0.7587, 0.7645)

- From the chi-squared table with  $4 - 1 = 3$  degrees of freedom, we have (see, e.g., Ross, 1987, p. 483)  $\chi_{0.975}^2 = 0.216$ ,  $\chi_{0.025}^2 = 9.348$ . Thus a 95% confidence interval for  $\sigma_1^2$  is  $(3 \times 3.280 \times 10^{-6}/9.348, 3 \times 3.280 \times 10^{-6}/0.216)$ , or  $(1.0526 \times 10^{-6}, 45,5556 \times 10^{-6})$ .
- In testing the hypotheses

$$H_0 : \mu_1 = 0.76 \text{ vs. } H_1 : \mu_1 > 0.76$$

with  $\alpha = 0.01$  when  $\sigma_1^2$  is unknown, the critical region is  $\bar{x}_1 > 0.76 + 4.541 \times 0.001811/\sqrt{4} = 0.7641$ . Since the observed value  $\bar{x}_1$  is 0.7616,  $H_0$  is accepted. That is, we assert that there is no significant evidence to call for the rejection of  $H_0$ .

### Two-Sample Case

If we assume that the two populations have a common unknown variance, we can use the Student's  $t$  distribution (with degree of freedom  $v = 4 + 5 - 2 = 7$ ) to obtain confidence intervals and to test hypotheses for  $\mu_1 - \mu_2$ . We first note that the data given above yield

$$\begin{aligned} S_p^2 &= \frac{1}{7}(3 \times 3.280 + 4 \times 3.355) \times 10^{-6} \\ &= 3.3229 \times 10^{-6} \\ S_p &= 1.8229 \times 10^{-3} \quad v = S_p \sqrt{1/4 + 1/5} = 1.2228 \times 10^{-3} \end{aligned}$$

and  $\bar{X}_1 - \bar{X}_2 = 0.0062$ .

- A 98% confidence interval for  $\mu_1 - \mu_2$  is  $(0.0062 - 2.998v, 0.0062 + 2.998v)$  or  $(0.0025, 0.0099)$ .
- In testing the hypotheses  $H_0: \mu_1 = \mu_2$  (i.e.,  $\mu_1 - \mu_2 = 0$ ) vs.  $H_1: \mu_1 > \mu_2$  with  $\alpha = 0.05$ , the critical region is  $(\bar{X}_1 - \bar{X}_2) > 1.895v = 2.3172 \times 10^{-3}$ . Thus  $H_0$  is rejected; i.e., we conclude that there is significant evidence to indicate that  $\mu_1 > \mu_2$  may be true.
- In testing the hypotheses  $H_0: \mu_1 = \mu_2$  vs.  $\mu_1 \neq \mu_2$  with  $\alpha = 0.02$ , the critical region is  $|\bar{X}_1 - \bar{X}_2| > 2.998v = 3.6660 \times 10^{-3}$ . Thus  $H_0$  is rejected. We note that the conclusion here is consistent with the result that, with confidence probability  $1 - \alpha = 0.98$ , the confidence interval for  $(\mu_1 - \mu_2)$  does not contain the origin.

### Concluding Remarks

The history of probability and statistics goes back to the days of the celebrated mathematicians K. F. Gauss and P. S. Laplace. (The normal distribution, in fact, is also called the Gaussian distribution.) The theory and methods of classical statistical analysis began its developments in the late 1800s and early 1900s when F. Galton and R.A. Fisher applied statistics to their research in genetics, when Karl Pearson developed the chi-square goodness-of-fit method for stochastic modeling, and when E.S. Pearson and J. Neyman developed the theory of hypotheses testing. Today statistical methods have been found useful in analyzing experimental data in biological science and medicine, engineering, social sciences, and many other fields. A non-technical review on some of the applications is Hacking (1984).

Applications of statistics in engineering include many topics. In addition to those treated in this section, other important ones include sampling inspection and quality (process) control, reliability, regression analysis and prediction, design of engineering experiments, and analysis of variance. Due to space limitations, these topics are not treated here. The reader is referred to textbooks in this area for further information. There are many well-written books that cover most of these topics, the following short list consists of a small sample of them.

## 19.12 Numerical Methods

William F. Ames

### Introduction

Since many mathematical models of physical phenomena are not solvable by available mathematical methods one must often resort to approximate or numerical methods. These procedures do not yield exact results in the mathematical sense. This inexact nature of numerical results means we must pay attention to the errors. The two errors that concern us here are *round-off errors* and *truncation errors*.

Round-off errors arise as a consequence of using a number specified by  $m$  correct digits to approximate a number which requires more than  $m$  digits for its exact specification. For example, using 3.14159 to approximate the irrational number  $\pi$ . Such errors may be especially serious in matrix inversion or in any area where a very large number of numerical operations are required. Some attempts at handling these errors are called *enclosure methods*. (Adams and Kulisch, 1993).

Truncation errors arise from the substitution of a finite number of steps for an infinite sequence of steps (usually an iteration) which would yield the exact result. For example, the iteration  $y_n(x) = 1 + \int_0^x xy_{n-1}(t)dt$ ,  $y(0) = 1$  is only carried out for a *few steps*, but it converges in *infinitely* many steps.

The study of some errors in a computation is related to the theory of probability. In what follows, a relation for the error will be given in certain instances.

### Linear Algebra Equations

A problem often met is the determination of the solution vector  $u = (u_1, u_2, \dots, u_n)^T$  for the set of linear equations  $Au = v$  where  $A$  is the  $n \times n$  square matrix with coefficients,  $a_{ij}$  ( $i, j = 1, \dots, n$ ),  $v = (v_1, \dots, v_n)^T$  and  $i$  denotes the row index and  $j$  the column index.

There are many numerical methods for finding the solution,  $u$ , of  $Au = v$ . The direct inversion of  $A$  is usually too expensive and is not often carried out unless it is needed elsewhere. We shall only list a few methods. One can check the literature for the many methods and computer software available. Some of the software is listed in the References section at the end of this chapter. The methods are usually subdivided into *direct* (once through) or *iterative* (repeated) procedures.

In what follows, it will often be convenient to partition the matrix  $A$  into the form  $A = U + D + L$ , where  $U$ ,  $D$ , and  $L$  are matrices having the same elements as  $A$ , respectively, above the main diagonal, on the main diagonal, and below the main diagonal, and zeros elsewhere. Thus,

$$U = \begin{bmatrix} 0 & a_{12} & & \cdots & a_{1n} \\ 0 & 0 & a_{23} & \cdots & a_{2n} \\ \vdots & \cdots & & \cdots & \\ 0 & 0 & \cdots & \cdots & 0 \end{bmatrix}$$

We also assume the  $u_j$ s are not all zero and  $\det A \neq 0$  so the solution is unique.

### Direct Methods

*Gauss Reduction.* This classical method has spawned many variations. It consists of dividing the first equation by  $a_{11}$  (if  $a_{11} = 0$ , reorder the equations to find an  $a_{11} \neq 0$ ) and using the result to eliminate the terms in  $u_1$  from each of the succeeding equations. Next, the modified second equation is divided by  $a'_{22}$  (if  $a'_{22} = 0$ , a reordering of the modified equations may be necessary) and the resulting equation is used to eliminate all terms in  $u_2$  in the succeeding modified equations. This elimination is done  $n$  times resulting in a triangular system:

$$\begin{aligned}
 u_1 + a'_{12}u_2 + \cdots + a'_{1n}u_n &= v'_1 \\
 0 + u_2 + \cdots + a'_{2n}u_n &= v'_2 \\
 &\dots \\
 0 + \cdots + u_{n-1} + a'_{n-1,n}u_n &= v'_{n-1} \\
 u_n &= v'_n
 \end{aligned}$$

where  $a'_{ij}$  and  $v'_j$  represent the specific numerical values obtained by this process. The solution is obtained by working backward from the last equation. Various modifications, such as the Gauss-Jordan reduction, the Gauss-Doolittle reduction, and the Crout reduction, are described in the classical reference authored by Bodewig (1956). Direct methods prove very useful for sparse matrices and banded matrices that often arise in numerical calculation for differential equations. Many of these are available in computer packages such as IMSL, Maple, Matlab, and Mathematica.

*The Tridiagonal Algorithm.* When the linear equations are tridiagonal, the system

$$\begin{aligned}
 b_1u_1 + c_1u_2 &= d_1 \\
 a_iu_{i-1} + b_iu_i + c_iu_{i+1} &= d_i \\
 a_nu_{n-1} + b_nu_n &= d_n, \quad i = 2, 3, \dots, n-1
 \end{aligned}$$

can be solved explicitly for the unknown, thereby eliminating any matrix operations.

The Gaussian elimination process transforms the system into a simpler one of *upper bidiagonal* form. We designate the coefficients of this new system by  $a'_i, b'_i, c'_i$  and  $d'_i$ , and we note that

$$\begin{aligned}
 a'_i &= 0, \quad i = 2, 3, \dots, n \\
 b'_i &= 1, \quad i = 1, 2, \dots, n
 \end{aligned}$$

The coefficients  $c'_i$  and  $d'_i$  are calculated successively from the relations

$$\begin{aligned}
 c'_1 &= \frac{c_1}{b_1} & d'_1 &= \frac{d_1}{b_1} \\
 c'_{i+1} &= \frac{c_{i+1}}{b_{i+1} - a_{i+1}c'_i} \\
 d'_{i+1} &= \frac{d_{i+1} - a_{i+1}d'_i}{b_{i+1} - a_{i+1}c'_i}, \quad i = 1, 2, \dots, n-1
 \end{aligned}$$

and, of course,  $c_n = 0$ .

Having completed the elimination we examine the new system and see that the  $n$ th equation is now

$$u_n = d'_n$$

Substituting this value into the  $(n-1)$ st equation,

$$u_{n-1} + c'_{n-1}u_n = d'_{n-1}$$

we have

$$u_{n-1} = d'_{n-1} - c'_{n-1}u_n$$

Thus, starting with  $u_n$ , we have successively the solution for  $u_i$  as

$$u_i = d'_i - c'_i u_{i+1}, \quad i = n-1, n-2, \dots, 1$$

*Algorithm for Pentadiagonal Matrix.* The equations to be solved are

$$a_i u_{i-2} + b_i u_{i-1} + c_i u_i + d_i u_{i+1} + e_i u_{i+2} = f_i$$

for  $1 \leq i \leq R$  with  $a_1 = b_1 = a_2 = e_{R-1} = d_R = e_R = 0$ .

The algorithm is as follows. First, compute

$$\delta_1 = d_1/c_1$$

$$\lambda_1 = e_1/c_1$$

$$\gamma_1 = f_1/c_1$$

and

$$\mu_2 = c_2 - b_2 \delta_1$$

$$\delta_2 = (d_2 - b_2 \lambda_1)/\mu_2$$

$$\lambda_2 = e_2/\mu_2$$

$$\gamma_2 = (f_2 - b_2 \gamma_1)/\mu_2$$

Then, for  $3 \leq i \leq R-2$ , compute

$$\beta_i = b_i - a_i \delta_{i-2}$$

$$\mu_i = c_i - \beta_i \delta_{i-1} - a_i \lambda_{i-2}$$

$$\delta_i = (d_i - \beta_i \lambda_{i-1})/\mu_i$$

$$\lambda_i = e_i/\mu_i$$

$$\gamma_i = (f_i - \beta_i \gamma_{i-1} - a_i \gamma_{i-2})/\mu_i$$

Next, compute

$$\beta_{R-1} = b_{R-1} - a_{R-1} \delta_{R-3}$$

$$\mu_{R-1} = c_{R-1} - \beta_{R-1} \delta_{R-2} - a_{R-1} \lambda_{R-3}$$

$$\delta_{R-1} = (d_{R-1} - \beta_{R-1} \lambda_{R-2})/\mu_{R-1}$$

$$\gamma_{R-1} = (f_{R-1} - \beta_{R-1} \gamma_{R-2} - a_{R-1} \gamma_{R-3})/\mu_{R-1}$$

and

$$\begin{aligned}\beta_R &= b_R - a_R \delta_{R-2} \\ \mu_R &= c_R - \beta_R \delta_{R-1} - a_R \lambda_{R-2} \\ \gamma_R &= (f_R - \beta_R \gamma_{R-1} - a_R \gamma_{R-2}) / \mu_R\end{aligned}$$

The  $\beta_i$  and  $\mu_i$  are used only to compute  $\delta_i$ ,  $\lambda_i$ , and  $\gamma_i$ , and need not be stored after they are computed. The  $\delta_i$ ,  $\lambda_i$ , and  $\gamma_i$  must be stored, as they are used in the back solution. This is

$$\begin{aligned}u_R &= \gamma_R \\ u_{R-1} &= \gamma_{R-1} - \delta_{R-1} u_R\end{aligned}$$

and

$$u_i = \gamma_i - \delta_i u_{i+1} - \lambda_i u_{i+2}$$

for  $R - 2 \geq i \geq 1$ .

*General Band Algorithm.* The equations are of the form

$$\begin{aligned}A_j^{(M)} X_{j-M} + A_j^{(M-1)} X_{j-M+1} + \cdots + A_j^{(2)} X_{j-2} + A_j^{(1)} X_{j-1} + B_j X_j \\ + C_j^{(1)} X_{j+1} + C_j^{(2)} X_{j+2} + \cdots + C_j^{(M-1)} X_{j+M-1} + C_j^{(M)} X_{j+M} = D_j\end{aligned}$$

for  $1 \leq j \leq N$ ,  $N \geq M$ . The algorithm used is as follows:

$$\begin{aligned}\alpha_j^{(k)} = A_j^{(k)} = 0, \quad \text{for } k \geq j \\ C_j^{(k)} = 0, \quad \text{for } k \geq N + 1 - j\end{aligned}$$

The forward solution ( $j = 1, \dots, N$ ) is

$$\begin{aligned}\alpha_j^{(k)} &= A_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p)} W_{j-p}^{(p-k)}, \quad k = M, \dots, 1 \\ \beta_j &= B_j - \sum_{p=1}^M \alpha_j^{(p)} W_{j-p}^{(p)} \\ W_j^{(k)} &= \left( C_j^{(k)} - \sum_{p=k+1}^{p=M} \alpha_j^{(p-k)} W_{j-(p-k)}^{(p)} \right) / \beta_j, \quad k = 1, \dots, M \\ \gamma_j &= \left( D_j - \sum_{p=1}^M \alpha_j^{(p)} \gamma_{j-p} \right) / \beta_j\end{aligned}$$

The back solution ( $j = N, \dots, 1$ ) is

$$X_j = \gamma_j - \sum_{p=1}^M W_j^{(p)} X_{j+p}$$

*Cholesky Decomposition.* When the matrix  $A$  is a symmetric and positive definite, as it is for many discretizations of self-adjoint positive definite boundary value problems, one can improve considerably on the band procedures by using the Cholesky decomposition. For the system  $Au = v$ , the Matrix  $A$  can be written in the form

$$A = (I + L)D(I + U)$$

where  $L$  is lower triangular,  $U$  is upper triangular, and  $D$  is diagonal. If  $A = A'$  ( $A'$  represents the transpose of  $A$ ), then

$$A = A' = (I + U)' D(I + L)'$$

Hence, because of the uniqueness of the decomposition.

$$I + L = (I + U)' = I + U'$$

and therefore,

$$A = (I + U)' D(I + U)$$

that is,

$$A = B'B, \text{ where } B = \sqrt{D}(I + U)$$

The system  $Au = v$  is then solved by solving the two triangular system

$$B'w = v$$

followed by

$$Bu = w$$

To carry out the decomposition  $A = B'B$ , all elements of the first row of  $A$ , and of the derived system, are divided by the square root of the (positive) leading coefficient. This yields smaller rounding errors than the banded methods because the relative error of  $\sqrt{a}$  is only half as large as that of  $a$  itself. Also, taking the square root brings numbers nearer to each other (i.e., the new coefficients do not differ as widely as the original ones do). The actual computation of  $B = (b_{ij}), j > i$ , is given in the following:

$$\begin{aligned}
 b_{11} &= (a_{11})^{1/2}, & b_{1j} &= a_{ij}/b_{11}, \quad j \geq 2 \\
 b_{22} &= (a_{22} - b_{12}^2)^{1/2}, & b_{2j} &= (a_{2j} - b_{12}b_{1j})/b_{22} \\
 b_{33} &= (a_{33} - b_{13}^2 - b_{23}^2)^{1/2}, & b_{3j} &= (a_{3j} - b_{13}b_{1j} - b_{23}b_{2j})/b_{33} \\
 &\vdots & & \\
 b_{ii} &= \left( a_{ii} - \sum_{k=1}^{i-1} b_{ki}^2 \right)^{1/2}, & b_{ij} &= \left( a_{ij} - \sum_{k=1}^{i-1} b_{ki}b_{kj} \right) / b_{ii}, \quad i \geq 2, j \geq 2
 \end{aligned}$$

### Iterative Methods

Iterative methods consist of repeated application of an often simple algorithm. They yield the exact answer only as the limit of a sequence. They can be programmed to take care of zeros in  $A$  and are self-correcting. Their structure permits the use of convergence accelerators, such as overrelaxation, Aitkins acceleration, or Chebyshev acceleration.

Let  $a_{ii} > 0$  for all  $i$  and  $\det A \neq 0$ . With  $A = U + D + L$  as previously described, several iteration methods are described for  $(U + D + L)u = v$ .

*Jacobi Method (Iteration by total steps).* Since  $u = -D^{-1}[U + L]u + D^{-1}v$ , the iteration  $u^{(k)}$  is  $u^{(k)} = -D^{-1}[U + L]u^{(k-1)} + D^{-1}v$ . This procedure has a slow convergent rate designated by  $R$ ,  $0 < R \ll 1$ .

*Gauss-Seidel Method (Iteration by single steps).*  $u^{(k)} = -(L + D)^{-1}Uu^{(k-1)} + (L + D)^{-1}v$ . Convergence rate is  $2R$ , twice as fast as that of the Jacobi method.

*Gauss-Seidel with Successive Overrelaxation (SOR).* Let  $\bar{u}_i^{(k)}$  be the  $i$ th components of the Gauss-Seidel iteration. The SOR technique is defined by

$$u_i^{(k)} = (1 - \omega)u_i^{(k-1)} + \omega\bar{u}_i^{(k)}$$

where  $1 < \omega < 2$  is the overrelaxation parameter. The full iteration is  $u^{(k)} = (D + \omega L)^{-1}\{(1 - \omega)D - \omega U\}u^{(k-1)} + \omega v$ . Optimal values of  $\omega$  can be computed and depend upon the properties of  $A$  (Ames, 1993). With optimal values of  $\omega$ , the convergence rate of this method is  $2R\sqrt{2}$  which is much larger than that for Gauss-Seidel ( $R$  is usually much less than one).

For other acceleration techniques, see the literature (Ames, 1993).

## Nonlinear Equations in One Variable

### Special Methods for Polynomials

The polynomial  $P(x) = a_0x^n + a_1x^{n-1} + \cdots + a_{n-1}x + a_n = 0$ , with real coefficients  $a_j$ ,  $j = 0, \dots, n$ , has exactly  $n$  roots which may be real or complex.

If all the coefficients of  $P(x)$  are integers, then any rational roots, say  $r/s$  ( $r$  and  $s$  are integers with no common factors), of  $P(x) = 0$  must be such that  $r$  is an integral divisor of  $a_n$  and  $s$  is an integral division of  $a_0$ . Any polynomial with rational coefficients may be converted into one with integral coefficients by multiplying the polynomial by the lowest common multiple of the denominators of the coefficients.

**Example.**  $x^4 - 5x^2/3 + x/5 + 3 = 0$ . The lowest common multiple of the denominators is 15. Multiplying by 15, which does not change the roots, gives  $15x^4 - 25x^2 + 3x + 45 = 0$ . The only possible rational roots  $r/s$  are such that  $r$  may have the value  $\pm 45, \pm 15, \pm 5, \pm 3$ , and  $\pm 1$ , while  $s$  may have the values  $\pm 15$ ,

$\pm 5$ ,  $\pm 3$ , and  $\pm 1$ . All possible rational roots, with no common factors, are formed using all possible quotients.

If  $a_0 > 0$ , the first negative coefficient is preceded by  $k$  coefficients which are positive or zero, and  $G$  is the largest of the absolute values of the negative coefficients, then each real root is less than  $1 + \sqrt[k]{G/a_0}$  (upper bound on the real roots). For a lower bound to the real roots, apply the criterion to  $P(-x) = 0$ .

**Example.**  $P(x) = x^5 + 3x^4 - 2x^3 - 12x + 2 = 0$ . Here  $a_0 = 1$ ,  $G = 12$ , and  $k = 2$ . Thus, the upper bound for the real roots is  $1 + \sqrt[2]{12} \approx 4.464$ . For the lower bound,  $P(-x) = -x^5 + 3x^4 + 2x^3 + 12x + 2 = 0$ , which is equivalent to  $x^5 - 3x^4 - 2x^3 - 12x - 2 = 0$ . Here  $k = 1$ ,  $G = 12$ , and  $a_0 = 1$ . A lower bound is  $-(1 + 12) = -13$ . Hence all real roots lie in  $-13 < x < 1 + \sqrt[2]{12}$ .

A useful *Descartes rule of signs* for the number of positive or negative real roots is available by observation for polynomials with real coefficients. The number of positive real roots is either equal to the number of sign changes,  $n$ , or is less than  $n$  by a positive *even* integer. The number of negative real roots is either equal to the number of sign changes,  $n$ , of  $P(-x)$ , or is less than  $n$  by a positive even integer.

**Example.**  $P(x) = x^5 - 3x^3 - 2x^2 + x - 1 = 0$ . There are three sign changes, so  $P(x)$  has either three or one positive roots. Since  $P(-x) = -x^5 + 3x^3 - 2x^2 - 1 = 0$ , there are either two or zero negative roots.

### The Graeffe Root-Squaring Technique

This is an iterative method for finding the roots of the algebraic equation

$$f(x) = a_0x^p + a_1x^{p-1} + \dots + a_{p-1}x + a_p = 0$$

If the roots are  $r_1, r_2, r_3, \dots$ , then one can write

$$S_p = r_1^p \left( 1 + \frac{r_2^p}{r_1^p} + \frac{r_3^p}{r_1^p} + \dots \right)$$

and if one root is larger than all the others, say  $r_1$ , then for large enough  $p$  all terms (other than 1) would become negligible. Thus,

$$S_p \approx r_1^p$$

or

$$\lim_{p \rightarrow \infty} S_p^{1/p} = r_1$$

The Graeffe procedure provides an efficient way for computing  $S_p$  via a sequence of equations such that the roots of each equation are the squares of the roots of the preceding equations in the sequence. This serves the purpose of ultimately obtaining an equation whose roots are so widely separated in magnitude that they may be read approximately from the equation by inspection. The basic procedure is illustrated for a polynomial of degree 4:

$$f(x) = a_0x^4 + a_1x^3 + a_2x^2 + a_3x + a_4 = 0$$

Rewrite this as

$$a_0x^4 + a_2x^2 + a_4 = -a_1x^3 - a_3x$$

and square both sides so that upon grouping

$$a_0^2 x^8 + (2a_0 a_2 - a_1^2) x^6 + (2a_0 a_4 - 2a_1 a_3 + a_2^2) x^4 + (2a_2 a_4 - a_3^2) x^2 + a_4^2 = 0$$

Because this involves only even powers of  $x$ , we may set  $y = x^2$  and rewrite it as

$$a_0^2 y^4 + (2a_0 a_2 - a_1^2) y^3 + (2a_0 a_4 - 2a_1 a_3 + a_2^2) y^2 + (2a_2 a_4 - a_3^2) y + a_4^2 = 0$$

whose roots are the squares of the original equation. If we repeat this process again, the new equation has roots which are the fourth power, and so on. After  $p$  such operations, the roots are  $2^p$  (original roots). If at any stage we write the coefficients of the unknown in sequence

$$a_0^{(p)} \quad a_1^{(p)} \quad a_2^{(p)} \quad a_3^{(p)} \quad a_4^{(p)}$$

then, to get the new sequence  $a_i^{(p+1)}$ , write  $a_i^{(p+1)} = 2a_0^{(p)}$  (times the symmetric coefficient) with respect to  $a_i^{(p)} - 2a_1^{(p)}$  (times the symmetric coefficient)  $\dots (-1)^i a_i^{(p)2}$ . Now if the roots are  $r_1, r_2, r_3,$  and  $r_4$ , then  $a_1/a_0 = -\sum_{i=1}^4 r_i, a_1^{(1)}/a_0^{(1)} = -\sum r_i^2, \dots, a_i^{(p)}/a_0^{(p)} = -\sum r_i^{2^p}$ . If the roots are all distinct and  $r_1$  is the largest in magnitude, then eventually

$$r_1^{2^p} \approx -\frac{a_1^{(p)}}{a_0^{(p)}}$$

And if  $r_2$  is the next largest in magnitude, then

$$r_2^{2^p} \approx -\frac{a_2^{(p)}}{a_1^{(p)}}$$

And, in general  $a_n^{(p)}/a_{n-1}^{(p)} \approx -r_n^{2^p}$ . This procedure is easily generalized to polynomials of arbitrary degree and specialized to the case of multiple and complex roots.

Other methods include Bernoulli iteration, Bairstow iteration, and Lin iteration. These may be found in the cited literature. In addition, the methods given below may be used for the numerical solution of polynomials.

## General Methods for Nonlinear Equations in One Variable

### Successive Substitutions

Let  $f(x) = 0$  be the nonlinear equation to be solved. If this is rewritten as  $x = F(x)$ , then an iterative scheme can be set up in the form  $x_{k+1} = F(x_k)$ . To start the iteration, an initial guess must be obtained graphically or otherwise. The convergence or divergence of the procedure depends upon the method of writing  $x = F(x)$ , of which there will usually be several forms. A general rule to ensure convergence cannot be given. However, if  $a$  is a root of  $f(x) = 0$ , a necessary condition for convergence is that  $|F'(x)| < 1$  in that interval about  $a$  in which the iteration proceeds (this means the iteration cannot converge unless  $|F'(x)| < 1$ , but it does not ensure convergence). This process is called *first order* because the error in  $x_{k+1}$  is proportional to the first power of the error in  $x_k$ .

**Example.**  $f(x) = x^3 - x - 1 = 0$ . A rough plot shows a real root of approximately 1.3. The equation can be written in the form  $x = F(x)$  in several ways, such as  $x = x^3 - 1$ ,  $x = 1/(x^2 - 1)$ , and  $x = (1 + x)^{1/3}$ . In the first case,  $F'(x) = 3x^2 = 5.07$  at  $x = 1.3$ ; in the second,  $F'(1.3) = 5.46$ ; only in the third case

is  $F'(1.3) < 1$ . Hence, only the third iterative process has a chance to converge. This is illustrated in the iteration table below.

Step $k$	$x = \frac{1}{x^2 - 1}$	$x = x^3 - 1$	$x = (1 + x)^{1/3}$
0	1.3	1.3	1.3
1	1.4493	1.197	1.32
2	0.9087	0.7150	1.3238
3	-5.737	-0.6345	1.3247
4	...	...	1.3247

### Numerical Solution of Simultaneous Nonlinear Equations

The techniques illustrated here will be demonstrated for two simultaneous equations —  $f(x, y) = 0$  and  $g(x, y) = 0$ . They immediately generalize to more than two simultaneous equations.

#### The Method of Successive Substitutions

The two simultaneous equations can be written in various ways in equivalent forms

$$x = F(x, y)$$

$$y = G(x, y)$$

and the method of successive substitutions can be based on

$$x_{k+1} = F(x_k, y_k)$$

$$y_{k+1} = G(x_k, y_k)$$

Again, the procedure is of the first order and a necessary condition for convergence is

$$\left| \frac{\partial F}{\partial x} \right| + \left| \frac{\partial F}{\partial y} \right| < 1 \qquad \left| \frac{\partial G}{\partial x} \right| + \left| \frac{\partial G}{\partial y} \right| < 1$$

in the iteration neighborhood of the true solution.

#### The Newton-Raphson Procedure

Using the two simultaneous equation, start from an approximate, say  $(x_0, y_0)$ , obtained graphically or from a two-way table. Then, solve successively the linear equations

$$\Delta x_k \frac{\partial f}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial f}{\partial y}(x_k, y_k) = -f(x_k, y_k)$$

$$\Delta x_k \frac{\partial g}{\partial x}(x_k, y_k) + \Delta y_k \frac{\partial g}{\partial y}(x_k, y_k) = -g(x_k, y_k)$$

for  $\Delta x_k$  and  $\Delta y_k$ . Then, the  $k + 1$  approximation is given from  $x_{k+1} = x_k + \Delta x_k, y_{k+1} = y_k + \Delta y_k$ . A modification consists in solving the equations with  $(x_k, y_k)$  replaced by  $(x_0, y_0)$  (or another suitable pair later on in the iteration) in the derivatives. This means the derivatives (and therefore the coefficients of  $\Delta x_k, \Delta y_k$ ) are independent of  $k$ . Hence, the results become

$$\Delta x_k = \frac{-f(x_k, y_k)(\partial g/\partial y)(x_0, y_0) + g(x_k, y_k)(\partial f/\partial y)(x_0, y_0)}{(\partial f/\partial x)(x_0, y_0)(\partial g/\partial y)(x_0, y_0) - (\partial f/\partial y)(x_0, y_0)(\partial g/\partial x)(x_0, y_0)}$$

$$\Delta y_k = \frac{-g(x_k, y_k)(\partial f/\partial x)(x_0, y_0) + f(x_k, y_k)(\partial g/\partial x)(x_0, y_0)}{(\partial f/\partial x)(x_0, y_0)(\partial g/\partial y)(x_0, y_0) - (\partial f/\partial y)(x_0, y_0)(\partial g/\partial x)(x_0, y_0)}$$

and  $x_{k+1} = \Delta x_k + x_k$ ,  $y_{k+1} = \Delta y_k + y_k$ . Such an alteration of the basic technique reduces the rapidity of convergence.

### Example

$$f(x, y) = 4x^2 + 6x - 4xy + 2y^2 - 3$$

$$g(x, y) = 2x^2 - 4xy + y^2$$

By plotting, one of the approximate roots is found to be  $x_0 = 0.4$ ,  $y_0 = 0.3$ . At this point, there results  $\partial f/\partial x = 8$ ,  $\partial f/\partial y = -0.4$ ,  $\partial g/\partial x = 0.4$ , and  $\partial g/\partial y = -1$ . Hence,

$$x_{k+1} = x_k + \Delta x_k = x_k + \frac{-f(x_k, y_k) - 0.4g(x_k, y_k)}{8(-1) - (-0.4)(0.4)}$$

$$= x_k - 0.12755f(x_k, y_k) - 0.05102g(x_k, y_k)$$

and

$$y_{k+1} = y_k - 0.05102f(x_k, y_k) + 1.02041g(x_k, y_k)$$

The first few iteration steps are shown in the following table.

Step $k$	$x_k$	$y_k$	$f(x_k, y_k)$	$g(x_k, y_k)$
0	0.4	0.3	-0.26	0.07
1	0.43673	0.24184	0.078	0.0175
2	0.42672	0.25573	-0.0170	-0.007
3	0.42925	0.24943	0.0077	0.0010

### Methods of Perturbation

Let  $f(x) = 0$  be the equation. In general, the iterative relation is

$$x_{k+1} = x_k - \frac{f(x_k)}{\alpha_k}$$

where the iteration begins with  $x_0$  as an initial approximation and  $\alpha_k$  is some functional.

*The Newton-Raphson Procedure.* This variant chooses  $\alpha_k = f'(x_k)$  where  $f' = df/dx$  and geometrically consists of replacing the graph of  $f(x)$  by the tangent line at  $x = x_k$  in each successive step. If  $f'(x)$  and  $f''(x)$  have the same sign throughout an interval  $a \leq x \leq b$  containing the solution, with  $f(a)$  and  $f(b)$  of opposite signs, then the process converges starting from any  $x_0$  in the interval  $a \leq x \leq b$ . The process is second order.

**Example**

$$f(x) = x - 1 + \frac{(0.5)^x - 0.5}{0.3}$$

$$f'(x) = 1 - 2.3105[0.5]^x$$

An approximate root (obtained graphically) is 2.

Step $k$	$x_k$	$f(x_k)$	$f'(x_k)$
0	2	0.1667	0.4224
1	1.605	-0.002	0.2655
2	1.6125	-0.0005	...

*The Method of False Position.* This variant is commenced by finding  $x_0$  and  $x_1$  such that  $f(x_0)$  and  $f(x_1)$  are of opposite signs. Then,  $\alpha_1$  = slope of secant line joining  $[x_0, f(x_0)]$  and  $[x_1, f(x_1)]$  so that

$$x_2 = x_1 - \frac{x_1 - x_0}{f(x_1) - f(x_0)} f(x_1)$$

In each following step,  $\alpha_k$  is the slope of the line joining  $[x_k, f(x_k)]$  to the most recently determined point where  $f(x_j)$  has the opposite sign from that of  $f(x_k)$ . This method is of first order.

**The Method of Wegstein**

This is a variant of the method of successive substitutions which forces or accelerates convergence. The iterative procedure  $x_{k+1} = F(x_k)$  is revised by setting  $\hat{x}_{k+1} = F(x_k)$  and then taking  $x_{k+1} = qx_k + (1 - q)\hat{x}_{k+1}$ . Wegstein found that suitably chosen  $qs$  are related to the basic process as follows:

Behavior of Successive Substitution Process	Range of Optimum $q$
Oscillatory convergence	$0 < q < 1/2$
Oscillatory divergence	$1/2 < q < 1$
Monotonic convergence	$q < 0$
Monotonic divergence	$1 < q$

At each step,  $q$  may be calculated to give a locally optimum value by setting

$$q = \frac{x_{k+1} - x_k}{x_{k+1} - 2x_k + x_{k-1}}$$

**The Method of Continuity**

In the case of  $n$  equations in  $n$  unknowns, when  $n$  is large, determining the approximate solution may involve considerable effort. In such a case, the method of continuity is admirably suited for use on either digital or analog computers. It consists basically of the introduction of an extra variable into the  $n$  equations

$$f_i(x_1, x_2, \dots, x_n) = 0, \quad i = 1, \dots, n$$

and replacing them by

$$f_i(x_1, x_2, \dots, x_n, \lambda) = 0, \quad i = 1, \dots, n$$

where  $\lambda$  is introduced in such a way that the functions depend in a simple way upon  $\lambda$  and reduce to an easily solvable system for  $\lambda = 0$  and to the original equations for  $\lambda = 1$ . A system of ordinary differential equations, with independent variable  $\lambda$ , is then constructed by differentiating with respect to  $\lambda$ . There results

$$\sum_{j=1}^n \frac{\partial f_i}{\partial x_j} \frac{dx_j}{d\lambda} + \frac{\partial f_i}{\partial \lambda} = 0$$

where  $x_1, \dots, x_n$  are considered as functions of  $\lambda$ . The equations are integrated, with initial conditions obtained with  $\lambda = 0$ , from  $\lambda = 0$  to  $\lambda = 1$ . If the solution can be continued to  $\lambda = 1$ , the values of  $x_1, \dots, x_n$  for  $\lambda = 1$  will be a solution of the original equations. If the integration becomes infinite, the parameter  $\lambda$  must be introduced in a different fashion. Integration of the differential equations (which are usually nonlinear in  $\lambda$ ) may be accomplished on an analog computer or by digital means using techniques described in a later section entitled "Numerical Solution of Ordinary Differential Equations."

### Example

$$f(x, y) = 2 + x + y - x^2 + 8xy + y^3 = 0$$

$$g(x, y) = 1 + 2x + 3y + x^2 + xy - ye^x = 0$$

Introduce  $\lambda$  as

$$f(x, y, \lambda) = (2 + x + y) + \lambda(-x^2 + 8xy + y^3) = 0$$

$$g(x, y, \lambda) = (1 + 2x - 3y) + \lambda(x^2 + xy - ye^x) = 0$$

For  $\lambda = 1$ , these reduce to the original equations, but, for  $\lambda = 0$ , they are the linear systems

$$x + y = -2$$

$$2x - 3y = -1$$

which has the unique solution  $x = -1.4$ ,  $y = -0.6$ . The differential equations in this case become

$$\frac{\partial f}{\partial x} \frac{dx}{d\lambda} + \frac{\partial f}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial f}{\partial \lambda}$$

$$\frac{\partial g}{\partial x} \frac{dx}{d\lambda} + \frac{\partial g}{\partial y} \frac{dy}{d\lambda} = -\frac{\partial g}{\partial \lambda}$$

or

$$\frac{dx}{d\lambda} = \frac{\frac{\partial f}{\partial y} \frac{\partial g}{\partial \lambda} - \frac{\partial f}{\partial \lambda} \frac{\partial g}{\partial y}}{\frac{\partial f}{\partial x} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial x}}$$

$$\frac{dy}{d\lambda} = \frac{\frac{\partial f}{\partial \lambda} \frac{\partial g}{\partial x} - \frac{\partial f}{\partial x} \frac{\partial g}{\partial \lambda}}{\frac{\partial f}{\partial x} \frac{\partial g}{\partial y} - \frac{\partial f}{\partial y} \frac{\partial g}{\partial x}}$$

Integrating in  $\lambda$ , with initial values  $x = -1.4$  and  $y = -0.6$  at  $\lambda = 0$ , from  $\lambda = 0$  to  $\lambda = 1$  gives the solution.

### Interpolation and Finite Differences

The practicing engineer constantly finds it necessary to refer to tables as sources of information. Consequently, interpolation, or that procedure of “reading between the lines of the table,” is a necessary topic in numerical analysis.

#### Linear Interpolation

If a function  $f(x)$  is approximately linear in a certain range, then the ratio  $[f(x_1) - f(x_0)]/(x_1 - x_0) = f[x_0, x_1]$  is approximately independent of  $x_0$  and  $x_1$  in the range. The linear approximation to the function  $f(x)$ ,  $x_0 < x < x_1$ , then leads to the interpolation formula

$$f(x) \approx f(x_0) + (x - x_0)f[x_0, x_1] \approx f(x_0) + \frac{x - x_0}{x_1 - x_0} [f(x_1) - f(x_0)]$$

$$\approx \frac{1}{x_1 - x_0} [(x_1 - x)f(x_0) - (x_0 - x)f(x_1)]$$

#### Divided Differences of Higher Order and Higher-Order Interpolation

The first-order divided difference  $f[x_0, x_1]$  was defined above. Divided differences of second and higher order are defined iteratively by

$$f[x_0, x_1, x_2] = \frac{f[x_1, x_2] - f[x_0, x_1]}{x_2 - x_0}$$

$$\vdots$$

$$f[x_0, x_1, \dots, x_k] = \frac{f[x_1, \dots, x_k] - f[x_0, x_1, \dots, x_{k-1}]}{x_k - x_0}$$

and a convenient form for computational purposes is

$$f[x_0, x_1, \dots, x_k] = \sum_{j=0}^k ' \frac{f(x_j)}{(x_j - x_0)(x_j - x_1) \cdots (x_j - x_k)}$$

for any  $k \geq 0$ , where the ' means the term  $(x_j - x_j)$  is omitted in the denominator. For example,

$$f[x_0, x_1, x_2] = \frac{f(x_0)}{(x_0 - x_1)(x_0 - x_2)} + \frac{f(x_1)}{(x_1 - x_0)(x_1 - x_2)} + \frac{f(x_2)}{(x_2 - x_0)(x_2 - x_1)}$$

If the accuracy afforded by a linear approximation is inadequate, a generally more accurate result may be based upon the assumption that  $f(x)$  may be approximated by a polynomial of degree 2 or higher over certain ranges. This assumption leads to *Newton's fundamental interpolation formula* with divided differences:

$$f(x) \approx f(x_0) + (x - x_0)f[x_0, x_1] + (x - x_0)(x - x_1)f[x_0, x_1, x_2] + (x - x_0)(x - x_1) \cdots (x - x_{n-1})f[x_0, x_1, \dots, x_n] + E_n(x)$$

where  $E_n(x) = \text{error} = [1/(n + 1)!]f^{(n+1)}(\xi)\pi(x)$  where  $\min(x_0, \dots, x_n) < \xi < \max(x_0, x_1, \dots, x_n, x)$  and  $\pi(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$ . In order to use this most effectively, one may first form a divided-difference table. For example, for third-order interpolation, the difference table is

$x_0$	$f(x_0)$			
$x_1$	$f(x_1)$	$f[x_0, x_1]$		
$x_2$	$f(x_2)$	$f[x_1, x_2]$	$f[x_0, x_1, x_2]$	
$x_3$	$f(x_3)$	$f[x_2, x_3]$	$f[x_1, x_2, x_3]$	$f[x_0, x_1, x_2, x_3]$

where each entry is given by taking the difference between diagonally adjacent entries to the left, divided by the abscissas corresponding to the ordinates intercepted by the diagonals passing through the calculated entry.

**Example.** Calculate by third-order interpolation the value of  $\cosh 0.83$  given  $\cosh 0.60$ ,  $\cosh 0.80$ ,  $\cosh 0.90$ , and  $\cosh 1.10$ .

$x_0 = 0.60$	1.185 47			
$x_1 = 0.80$	1.337 43	0.7598		
$x_2 = 0.90$	1.433 09	0.9566	0.6560	
$x_3 = 1.10$	1.668 52	1.1772	0.7353	0.1586

With  $n = 3$ , we have

$$\begin{aligned} \cosh 0.83 \approx & 1.185\ 47 + (0.23)(0.7598) + (0.23)(0.03)(0.6560) \\ & + (0.23)(0.03)(-0.07)(0.1586) = 1.364\ 64 \end{aligned}$$

which varies from the true value by 0.000 04.

### Lagrange Interpolation Formulas

The Newton formulas are expressed in terms of divided differences. It is often useful to have interpolation formulas expressed explicitly in terms of the ordinates involved. This is accomplished by the Lagrange interpolation polynomial of degree  $n$ :

$$y(x) = \sum_{j=0}^n \frac{\pi(x)}{(x - x_j)\pi'(x_j)} f(x_j)$$

where

$$\pi(x) = (x - x_0)(x - x_1) \cdots (x - x_n)$$

$$\pi'(x_j) = (x_j - x_0)(x_j - x_1) \cdots (x_j - x_n)$$

where  $(x_j - x_j)$  is the omitted factor. Thus,

$$f(x) = y(x) + E_n(x)$$

$$E_n(x) = \frac{1}{(n+1)!} \pi(x) f^{(n+1)}(\xi)$$

**Example.** The interpolation polynomial of degree 3 is

$$y(x) = \frac{(x - x_1)(x - x_2)(x - x_3)}{(x_0 - x_1)(x_0 - x_2)(x_0 - x_3)} f(x_0) + \frac{(x - x_0)(x - x_2)(x - x_3)}{(x_1 - x_0)(x_1 - x_2)(x_1 - x_3)} f(x_1)$$

$$+ \frac{(x - x_0)(x - x_1)(x - x_3)}{(x_2 - x_0)(x_2 - x_1)(x_2 - x_3)} f(x_2) + \frac{(x - x_0)(x - x_1)(x - x_2)}{(x_3 - x_0)(x_3 - x_1)(x_3 - x_2)} f(x_3)$$

Thus, directly from the data

$x$	0	1	3	4
$f(x)$	1	1	-1	2

we have as an interpolation polynomial  $y(x)$  for  $(x)$ :

$$y(x) = 1 \cdot \frac{(x - 1)(x - 3)(x - 4)}{(0 - 1)(0 - 3)(0 - 4)} + 1 \cdot \frac{x(x - 3)(x - 4)}{(1 - 0)(1 - 3)(1 - 4)}$$

$$- 1 \cdot \frac{x(x - 1)(x - 4)}{(3 - 0)(3 - 1)(3 - 4)} + 2 \cdot \frac{(x - 0)(x - 1)(x - 3)}{(4 - 0)(4 - 1)(4 - 3)}$$

**Other Difference Methods (Equally Spaced Ordinates)**

*Backward Differences.* The backward differences denoted by

$$\nabla f(x) = f(x) - f(x - h)$$

$$\nabla^2 f(x) = \nabla f(x) - \nabla f(x - h)$$

...

$$\nabla^n f(x) = \nabla^{n-1} f(x) - \nabla^{n-1} f(x - h)$$

are useful for calculation near the end of tabulated data.

*Central Differences.* The central differences denoted by

$$\delta f(x) = f\left(x + \frac{h}{2}\right) - f\left(x - \frac{h}{2}\right)$$

$$\delta^n f(x) = \delta^{n-1} f\left(x + \frac{h}{2}\right) - \delta^{n-1} f\left(x - \frac{h}{2}\right)$$

are useful for calculating at the interior points of tabulated data.

Also to be found in the literature are Gaussian, Stirling, Bessel, Everett, Comrie differences, and so forth.

### Inverse Interpolation

This is the process of finding the value of the independent variable or abscissa corresponding to a given value of the function when the latter is between two tabulated values of the abscissa. One method of accomplishing this is to use Lagrange's interpolation formula in the form

$$x = \psi(y) = \sum_{j=0}^n \frac{\pi(y)}{(y - y_j)\pi'(y_j)} x_j$$

where  $x$  is expressed as a function of  $y$ . Other methods revolve about methods of iteration.

### Numerical Differentiation

Numerical differentiation should be avoided wherever possible, particularly when data are empirical and subject to appreciable observation errors. Errors in data can affect numerical derivatives quite strongly (i.e., differentiation is a roughening process). When such a calculation must be made, it is usually desirable first to *smooth* the data to a certain extent.

### The Use of Interpolation Formulas

If the data are given over equidistant values of the independent variable  $x$ , an interpolation formula, such as the Newton formula, may be used, and the resulting formula differentiated analytically. If the independent variable is not at equidistant values, then Lagrange's formulas must be used. By differentiating three- and five-point Lagrange interpolation formulas, the following differentiation formulas result for equally spaced tabular points.

*Three-point Formulas.* Let  $x_0$ ,  $x_1$ , and  $x_2$  be the three points

$$f'(x_0) = \frac{1}{2h} [-3f(x_0) + 4f(x_1) - f(x_2)] + \frac{h^2}{3} f'''(\epsilon)$$

$$f'(x_1) = \frac{1}{2h} [-f(x_0) + f(x_2)] + \frac{h^2}{6} f'''(\epsilon)$$

$$f'(x_2) = \frac{1}{2h} [f(x_0) - 4f(x_1) + 3f(x_2)] + \frac{h^2}{3} f'''(\epsilon)$$

where the last term is an error term and  $\min_j x_j < \epsilon < \max_j x_j$ .

*Five-point Formulas.* Let  $x_0$ ,  $x_1$ ,  $x_2$ ,  $x_3$ , and  $x_4$  be the five values of the equally spaced independent variable and  $f_j = f(x_j)$ .

$$f'(x_0) = \frac{1}{12h} [-25f_0 + 48f_1 - 36f_2 + 16f_3 - 3f_4] + \frac{h^4}{5} f^{(v)}(\epsilon)$$

$$f'(x_1) = \frac{1}{12h}[-3f_0 - 10f_1 + 18f_2 - 6f_3 + f_4] - \frac{h^4}{20}f^{(v)}(\epsilon)$$

$$f'(x_2) = \frac{1}{12h}[f_0 - 8f_1 + 8f_3 - f_4] + \frac{h^4}{30}f^{(v)}(\epsilon)$$

$$f'(x_3) = \frac{1}{12h}[-f_0 + 6f_1 - 18f_2 + 10f_3 + 3f_4] - \frac{h^4}{20}f^{(v)}(\epsilon)$$

$$f'(x_4) = \frac{1}{12h}[3f_0 - 16f_1 + 36f_2 - 48f_3 + 25f_4] + \frac{h^4}{5}f^{(v)}(\epsilon)$$

and the last term is again an error term.

**Smoothing Techniques**

These techniques involve the approximation of the tabular data by a least squares fit of the data using some known functional form, usually a polynomial. In place of approximating  $f(x)$  by a single least squares polynomial of degree  $n$  over the entire range of the tabulation, it is often desirable to replace each tabulated value by the value taken on by a last squares polynomial of degree  $n$  relevant to a subrange of  $2M + 1$  points centered, where possible, at the point for which the entry is to be modified. Thus, each smoothed value replaces a tabulated value. Let  $f_i = f(x_i)$  be the tabular points and  $y_j =$  smoothed values. A first-degree least squares with three points would be

$$y_0 = \frac{1}{6}[5f_0 + 2f_1 - f_2]$$

$$y_1 = \frac{1}{3}[f_0 + f_1 + f_2]$$

$$y_2 = \frac{1}{6}[-f_0 + 2f_1 + 5f_2]$$

A first-degree least squares with five points would be

$$y_0 = \frac{1}{5}[3f_0 + 2f_1 + f_2 - f_4]$$

$$y_1 = \frac{1}{10}[4f_0 + 3f_1 + 2f_2 + f_3]$$

$$y_2 = \frac{1}{5}[f_0 + f_1 + f_2 + f_3 + f_4]$$

$$y_3 = \frac{1}{10}[f_0 + 2f_1 + 3f_2 + 4f_3]$$

$$y_4 = \frac{1}{5}[-f_0 + f_2 + 2f_3 + 3f_4]$$

Thus, for example, if first-degree, five-point least squares are used, the central formula is used for all values except the first two and the last two, where the off-center formulas are used. A third-degree least squares with seven points would be

$$\begin{aligned}
 y_0 &= \frac{1}{42} [39f_0 + 8f_1 - 4f_2 - 4f_3 + f_4 + 4f_5 - 2f_6] \\
 y_1 &= \frac{1}{42} [8f_0 + 19f_1 + 16f_2 + 6f_3 - 4f_4 - 7f_5 + 4f_6] \\
 y_2 &= \frac{1}{42} [-4f_0 + 16f_1 + 19f_2 + 12f_3 + 2f_4 - 4f_5 + f_6] \\
 y_3 &= \frac{1}{21} [-2f_0 + 3f_1 + 6f_2 + 7f_3 + 6f_4 + 3f_5 - 2f_6] \\
 y_4 &= \frac{1}{42} [f_0 - 4f_1 + 2f_2 + 12f_3 + 19f_4 + 16f_5 - 4f_6] \\
 y_5 &= \frac{1}{42} [4f_0 - 7f_1 - 4f_2 + 6f_3 + 16f_4 + 19f_5 + 8f_6] \\
 y_6 &= \frac{1}{42} [-2f_0 + 4f_1 + f_2 - 4f_3 - 4f_4 + 8f_5 + 39f_6]
 \end{aligned}$$

Additional smoothing formulas may be found in the references. After the data are smoothed, any of the interpolation polynomials, or an appropriate least squares polynomial, may be fitted and the results used to obtain the derivative.

### Least Squares Method

*Parabolic.* For five evenly spaced neighboring abscissas labeled  $x_{-2}$ ,  $x_{-1}$ ,  $x_0$ ,  $x_1$ , and  $x_2$ , and their ordinates  $f_{-2}$ ,  $f_{-1}$ ,  $f_0$ ,  $f_1$ , and  $f_2$ , assume a parabola is fit by least squares. There results for all interior points, except the first and last two points of the data, the formula for the numerical derivative:

$$f'_0 = \frac{1}{10h} [-2f_{-2} - f_{-1} + f_1 + 2f_2]$$

For the first two data points designated by 0 and  $h$ :

$$\begin{aligned}
 f'(0) &= \frac{1}{20h} [-21f(0) + 13f(h) + 17f(2h) - 9f(3h)] \\
 f'(h) &= \frac{1}{20h} [-11f(0) + 3f(h) + 7f(2h) + f(3h)]
 \end{aligned}$$

and for the last two given by  $\alpha - h$  and  $\alpha$ :

$$\begin{aligned}
 f'(\alpha - h) &= \frac{1}{20h} [-11f(\alpha) + 3f(\alpha - h) + 7f(\alpha - 2h) + f(\alpha - 3h)] \\
 f'(\alpha) &= \frac{1}{20h} [-21f(\alpha) + 13f(\alpha - h) + 17f(\alpha - 2h) - 9f(\alpha - 3h)]
 \end{aligned}$$

*Quartic (Douglas-Avakian).* A fourth-degree polynomial  $y = a + bx + cx^2 + dx^3 + ex^4$  is fitted to seven adjacent equidistant points (spacing  $h$ ) after a translation of coordinates has been made so that  $x = 0$  corresponds to the central point of the seven. Thus, these may be called  $-3h$ ,  $-2h$ ,  $-h$ ,  $0$ ,  $h$ ,  $2h$ , and  $3h$ . Let  $k =$  coefficient  $h$  for the seven points. This is, in  $-3h$ ,  $k = -3$ . Then, the coefficients for the polynomial are

$$\begin{aligned}
 a &= \frac{524 \sum f(kh) - 245 \sum k^2 f(kh) + 21 \sum k^4 f(kh)}{924} \\
 b &= \frac{397 \sum kf(kh)}{1512h} - \frac{7 \sum k^3 f(kh)}{216h} \\
 c &= \frac{-840 \sum f(kh) + 679 \sum k^2 f(kh) - 67 \sum k^4 f(kh)}{3168h^2} \\
 d &= \frac{-7 \sum kf(kh) + \sum k^3 f(kh)}{216h^3} \\
 e &= \frac{72 \sum f(kh) - 67 \sum k^2 f(kh) + 7 \sum k^4 f(kh)}{3168h^4}
 \end{aligned}$$

where all summations run from  $k = -3$  to  $k = +3$  and  $f(kh) =$  tabular value at  $kh$ . The slope of the polynomial at  $x = 0$  is  $dy/dx = b$ .

### Numerical Integration

Numerical evaluation of the finite integral  $\int_a^b f(x) dx$  is carried out by a variety of methods. A few are given here.

#### Newton-Cotes Formulas (Equally Spaced Ordinates)

*Trapezoidal Rule.* This formula consists of subdividing the interval  $a \leq x \leq b$  into  $n$  subintervals  $a$  to  $a + h$ ,  $a + h$  to  $a + 2h$ , ..., and replacing the graph of  $f(x)$  by the result of joining the ends of adjacent ordinates by line segments. If  $f_j = f(x_j) = f(a + jh)$ ,  $f_0 = f(a)$ , and  $f_n = f(b)$ , the integration formula is

$$\int_a^b f(x) dx = \frac{h}{2} [f_0 + 2f_1 + 2f_2 + \dots + 2f_{n-1} + f_n] + E_n$$

where  $|E_n| = (nh^3/12)|f''(\epsilon)| = [(b - a)^3/12n^2]|f''(\epsilon)|$ ,  $a < \epsilon < b$ . This procedure is not of high accuracy. However, if  $f''(x)$  is continuous in  $a < x < b$ , the error goes to zero as  $1/n^2$ ,  $n \rightarrow \infty$ .

*Parabolic Rule (Simpson's Rule).* This procedure consists of subdividing the interval  $a < x < b$  into  $n/2$  subintervals, each of length  $2h$ , where  $n$  is an even integer. Using the notation as above the integration formula is

$$\int_a^b f(x) dx = \frac{h}{3} [f_0 + 4f_1 + 2f_2 + 4f_3 + \dots + 4f_{n-3} + 2f_{n-2} + 4f_{n-1} + f_n] + E_n$$

where

$$|E_n| = \frac{nh^5}{180} |f^{(iv)}(\epsilon)| = \frac{(b - a)^5}{180n^4} |f^{(iv)}(\epsilon)| \quad a < \epsilon < b$$

This method approximates  $f(x)$  by a parabola on each subinterval. This rule is generally more accurate than the trapezoidal rule. It is the most widely used integration formula.

**Weddle's Rule.** This procedure consists of subdividing the integral  $a < x < b$  into  $n/6$  subintervals, each of length  $6h$ , where  $n$  is a multiple of 6. Using the notation from the trapezoidal rule, there results

$$\int_a^b f(x) dx = \frac{3h}{10} [f_0 + 5f_1 + f_2 + 6f_3 + f_4 + 5f_5 + 2f_6 + 5f_7 + f_8 + \cdots + 6f_{n-3} + f_{n-2} + 5f_{n-1} + f_n] + E_n$$

Note that the coefficients of  $f_j$  follow the rule 1, 5, 1, 6, 1, 5, 2, 5, 1, 6, 1, 5, 2, 5, etc.... This procedure consists of approximating  $f(x)$  by a polynomial of degree 6 on each subinterval. Here,

$$E_n = \frac{nh^7}{1400} [10f^{(6)}(\epsilon_1) + 9h^2 f^{(8)}(\epsilon_2)]$$

### Gaussian Integration Formulas (Unequally Spaced Abscissas)

These formulas are capable of yielding comparable accuracy with fewer ordinates than the equally spaced formulas. The ordinates are obtained by optimizing the distribution of the abscissas rather than by arbitrary choice. For the details of these formulas, Hildebrand (1956) is an excellent reference.

### Two-Dimensional Formula

Formulas for two-way integration over a rectangle, circle, ellipse, and so forth, may be developed by a double application of one-dimensional integration formulas. The two-dimensional generalization of the parabolic rule is given here. Consider the iterated integral  $\int_a^b \int_c^d f(x, y) dx dy$ . Subdivide  $c < x < d$  into  $m$  (even) subintervals of length  $h = (d - c)/m$ , and  $a < y < b$  into  $n$  (even) subintervals of length  $k = (b - a)/n$ . This gives a subdivision of the rectangle  $a \leq y \leq b$  and  $c \leq x \leq d$  into subrectangles. Let  $x_j = c + jh$ ,  $y_j = a + jk$ , and  $f_{i,j} = f(x_i, y_j)$ . Then,

$$\int_a^b \int_c^d f(x, y) dx dy = \frac{hk}{9} [(f_{0,0} + 4f_{1,0} + 2f_{2,0} + \cdots + f_{m,0}) + 4(f_{0,1} + 4f_{1,1} + 2f_{2,1} + \cdots + f_{m,1}) + 2(f_{0,2} + 4f_{1,2} + 2f_{2,2} + \cdots + f_{m,2}) + \cdots + (f_{0,n} + 4f_{1,n} + 2f_{2,n} + \cdots + f_{m,n})] + E_{m,n}$$

where

$$E_{m,n} = -\frac{hk}{90} \left[ mh^4 \frac{\partial^4 f(\epsilon_1, \eta_1)}{\partial x^4} + nk^4 \frac{\partial^4 f(\epsilon_2, \eta_2)}{\partial y^4} \right]$$

where  $\epsilon_1$  and  $\epsilon_2$  lie in  $c < x < d$ , and  $\eta_1$  and  $\eta_2$  lie in  $a < y < b$ .

## Numerical Solution of Ordinary Differential Equations

A number of methods have been devised to solve ordinary differential equations numerically. The general references contain some information. A numerical solution of a differential equation means a table of values of the function  $y$  and its derivatives over only a limited part of the range of the independent variable. Every differential equation of order  $n$  can be rewritten as  $n$  first-order differential equations. Therefore, the methods given below will be for first-order equations, and the generalization to simultaneous systems will be developed later.

### The Modified Euler Method

This method is simple and yields modest accuracy. If extreme accuracy is desired, a more sophisticated method should be selected. Let the first-order differential equation be  $dy/dx = f(x, y)$  with the initial condition  $(x_0, y_0)$  (i.e.,  $y = y_0$  when  $x = x_0$ ). The procedure is as follows.

Step 1. From the given initial conditions  $(x_0, y_0)$  compute  $y'_0 = f(x_0, y_0)$  and  $y''_0 = [\partial f(x_0, y_0)/\partial x] + [\partial f(x_0, y_0)/\partial y] y'_0$ . Then, determine  $y_1 = y_0 + h y'_0 + (h^2/2) y''_0$ , where  $h =$  subdivision of the independent variable.

Step 2. Determine  $y'_1 = f(x_1, y_1)$  where  $x_1 = x_0 + h$ . These prepare us for the following.

*Predictor Steps.*

Step 3. For  $n \geq 1$ , calculate  $(y_{n+1})_1 = y_n + 2h y'_n$ .

Step 4. Calculate  $(y'_{n+1})_1 = f[x_{n+1}, (y_{n+1})_1]$ .

*Corrector Steps.*

Step 5. Calculate  $(y_{n+1})_2 = y_n + (h/2) [(y'_{n+1})_1 + y'_n]$ , where  $y_n$  and  $y'_n$  without the subscripts are the previous values obtained by this process (or by steps 1 and 2).

Step 6.  $(y'_{n+1})_2 = f[x_{n+1}, (y_{n+1})_2]$ .

Step 7. Repeat the corrector steps 5 and 6 if necessary until the desired accuracy is produced in  $y_{n+1}, y'_{n+1}$ .

**Example.** Consider the equation  $y' = 2y^2 + x$  with the initial conditions  $y_0 = 1$  when  $x_0 = 0$ . Let  $h = 0.1$ . A few steps of the computation are illustrated.

Step	
1	$y'_0 = 2y_0^2 + x_0 = 2$ $y''_0 = 1 + 4y_0 y'_0 = 1 + 8 = 9$ $y_1 = 1 + (0.1)(2) + [(0.1)^2/2]9 = 1.245$
2	$y'_1 = 2y_1^2 + x_1 = 3.100 + 0.1 = 3.200$
3	$(y_2)_1 = y_0 + 2h y'_1 = 1 + 2(0.1)3.200 = 1.640$
4	$(y'_2)_1 = 2(y_2)_1^2 + x_2 = 5.592$
5	$(y_2)_2 = y_1 + (0.1/2)[(y'_2)_1 + y'_1] = 1.685$
6	$(y'_2)_2 = 2(y_2)_2^2 + x_2 = 5.878$
5 (repeat)	$(y_2)_3 = y_1 + (0.05)[(y'_2)_2 + y'_1] = 1.699$
6 (repeat)	$(y'_2)_3 = 2(y_2)_3^2 + x_2 = 5.974$

and so forth. This procedure. may be programmed for a computer. A discussion of the truncation error of this process may be found in Milne (1953).

**Modified Adam's Method**

The procedure given here was developed retaining third differences. It can then be considered as a more exact predictor-corrector method than the Euler method. The procedure is as follows for  $dy/dx = f(x, y)$  and  $h =$  interval size.

Steps 1 and 2 are the same as in Euler method.

*Predictor Steps.*

Step 3.  $(y_{n+1})_1 = y_n + (h/24) [55y'_n - 59y'_{n-1} + 37y'_{n-2} - 9y'_{n-3}]$ , where  $y'_n, y'_{n-1},$  etc..., are calculated in step 1.

Step 4.  $(y'_{n+1})_1 = f[x_{n+1}, (y_{n+1})_1]$ .

*Corrector Steps.*

Step 5.  $(y_{n+1})_2 = y_n + (h/24) [9(y'_{n+1})_1 + 19y'_n - 5y'_{n-1} + y'_{n-2}]$ .

Step 6.  $(y'_{n+1})_2 = f[x_{n+1}, (y_{n+1})_2]$ .

Step 7. Iterate steps 5 and 6 if necessary.

### Runge-Kutta Methods

These methods are self-starting and are inherently stable. Kopal (1955) is a good reference for their derivation and discussion. Third- and fourth-order procedures are given below for  $dy/dx = f(x, y)$  and  $h$  = interval size.

For third-order (error  $\approx h^4$ ).

$$k_0 = hf(x_n, y_n)$$

$$k_1 = hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_0)$$

$$k_2 = hf(x_n + h, y_n + 2k_1 - k_0)$$

and

$$y_{n+1} = y_n + \frac{1}{6}(k_0 + 4k_1 + k_2)$$

for all  $n \geq 0$ , with initial condition  $(x_0, y_0)$ .

For fourth-order (error  $\approx h^5$ ),

$$k_0 = hf(x_n, y_n)$$

$$k_1 = hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_0)$$

$$k_2 = hf(x_n + \frac{1}{2}h, y_n + \frac{1}{2}k_1)$$

$$k_3 = hf(x_n + h, y_n + k_2)$$

and

$$y_{n+1} = y_n + \frac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3)$$

**Example.** (Third-order) Let  $dy/dx = x - 2y$ , with initial condition  $y_0 = 1$  when  $x_0 = 0$ , and let  $h = 0.1$ . Clearly,  $x_n = nh$ . To calculate  $y_1$ , proceed as follows:

$$k_0 = 0.1[x_0 - 2y_0] = -0.2$$

$$k_1 = 0.1[0.05 - 2(1 - 0.1)] = -0.175$$

$$k_2 = 0.1[0.1 - 2(1 - 0.35 + 0.2)] = -0.16$$

$$y_1 = 1 + \frac{1}{6}(-0.2 - 0.7 - 0.16) = 0.8234$$

### Equations of Higher Order and Simultaneous Differential Equations

Any differential equation of second- or higher order can be reduced to a simultaneous system of first-order equations by the introduction of auxiliary variables. Consider the following equations:

$$\frac{d^2 x}{dt^2} + xy \frac{dx}{dt} + z = e^x$$

$$\frac{d^2 y}{dt^2} + xy \frac{dy}{dt} = 7 + t^2$$

$$\frac{d^2 z}{dt^2} + xz \frac{dz}{dt} + x = e^x$$

In the new variables  $x_1 = x$ ,  $x_2 = y$ ,  $x_3 = z$ ,  $x_4 = dx_1/dt$ ,  $x_5 = dx_2/dt$ , and  $x_6 = dx_3/dt$ , the equations become

$$\frac{dx_1}{dt} = x_4$$

$$\frac{dx_2}{dt} = x_5$$

$$\frac{dx_3}{dt} = x_6$$

$$\frac{dx_4}{dt} = -x_1 x_2 x_4 - x_3 + e^{x_1}$$

$$\frac{dx_5}{dt} = -x_3 x_2 x_5 + 7 + t^2$$

$$\frac{dx_6}{dt} = -x_1 x_3 x_6 - x_1 + e^{x_1}$$

which is a system of the general form

$$\frac{dx_i}{dt} = f_i(t, x_1, x_2, x_3, \dots, x_n)$$

where  $i = 1, 2, \dots, n$ . Such systems may be solved by simultaneous application of any of the above numerical techniques. A Runge-Kutta method for

$$\frac{dx}{dt} = f(t, x, y)$$

$$\frac{dy}{dt} = g(t, x, y)$$

is given below. The fourth-order procedure is shown.

Starting at the initial conditions  $x_0$ ,  $y_0$ , and  $t_0$ , the next values  $x_1$  and  $y_1$  are computed via the equations below (where  $\Delta t = h$ ,  $t_j = h + t_{j-1}$ ):

$$\begin{aligned}
 k_0 &= hf(t_0, x_0, y_0) & l_0 &= hg(t_0, x_0, y_0) \\
 k_1 &= hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right) & l_1 &= hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_0}{2}, y_0 + \frac{l_0}{2}\right) \\
 k_2 &= hf\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right) & l_2 &= hg\left(t_0 + \frac{h}{2}, x_0 + \frac{k_1}{2}, y_0 + \frac{l_1}{2}\right) \\
 k_3 &= hf(t_0 + h, x_0 + k_2, y_0 + l_2) & l_3 &= hg(t_0 + h, x_0 + k_2, y_0 + l_2)
 \end{aligned}$$

and

$$\begin{aligned}
 x_1 &= x_0 + \frac{1}{6}(k_0 + 2k_1 + 2k_2 + k_3) \\
 y_1 &= y_0 + \frac{1}{6}(l_0 + 2l_1 + 2l_2 + l_3)
 \end{aligned}$$

To continue the computation, replace  $t_0$ ,  $x_0$ , and  $y_0$  in the above formulas by  $t_1 = t_0 + h$ ,  $x_1$ , and  $y_1$  just calculated. Extension of this method to more than two equations follows precisely this same pattern.

## Numerical Solution of Integral Equations

This section considers a method of numerically solving the Fredholm integral equation of the second kind:

$$u(x) = f(x) + \lambda \int_a^b k(x, t)u(t) dt \quad \text{for } u(x)$$

The method discussed arises because a definite integral can be closely approximated by any of several numerical integration formulas (each of which arises by approximating the function by some polynomial over an interval). Thus, the definite integral can be replaced by an integration formula which becomes

$$u(x) = f(x) + \lambda(b-a) \left[ \sum_{i=1}^n c_i k(x, t_i) u(t_i) \right]$$

where  $t_1, \dots, t_n$  are points of subdivision of the  $t$  axis,  $a \leq t \leq b$ , and the  $c_i$ s are coefficients whose values depend upon the type of numerical integration formula used. Now, this must hold for all values of  $x$ , where  $a \leq x \leq b$ ; so it must hold for  $x = t_1, x = t_2, \dots, x = t_n$ . Substituting for  $x$  successively  $t_1, t_2, \dots, t_n$ , and setting  $u(t_i) = u_i$  and  $f(t_i) = f_i$ , we get  $n$  linear algebraic equations for the  $n$  unknowns  $u_1, \dots, u_n$ . That is,

$$u_i = f_i + (b-a) [c_1 k(t_i, t_1) u_1 + c_2 k(t_i, t_2) u_2 + \dots + c_n k(t_i, t_n) u_n], \quad i = 1, 2, \dots, n$$

These  $u_j$  may be solved for by the methods under the section entitled "Numerical Solution of Linear Equations."

## Numerical Methods for Partial Differential Equations

The ultimate goal of numerical (discrete) methods for partial differential equations (PDEs) is the reduction of continuous systems (projections) to discrete systems that are suitable for high-speed computer solutions. The user must be cautioned that the seeming elementary nature of the techniques holds pitfalls that can be seriously misleading. These approximations often lead to difficult mathematical questions of adequacy, accuracy, convergence, stability, and consistency. Convergence is concerned with

the approach of the approximate numerical solution to the exact solution as the number of mesh units increase indefinitely in some sense. Unless the numerical method can be shown to converge to the exact solution, the chosen method is unsatisfactory.

Stability deals in general with error growth in the calculation. As stated before, any numerical method involves truncation and round-off errors. These errors are not serious unless they grow as the computation proceeds (i.e., the method is unstable).

**Finite Difference Methods**

In these methods, the derivatives are replaced by various finite differences. The methods will be illustrated for problems in two space dimensions  $(x, y)$  or  $(x, t)$  where  $t$  is timelike. Using subdivisions  $\Delta x = h$  and  $\Delta y = k$  with  $u(i, j, k) = u_{i,j}$ , approximate  $u_x|_{i,j} = [(u_{i+1,j} - u_{i,j})/h] + O(h)$  (forward difference), a first-order  $[O(h)]$  method, or  $u_x|_{i,j} = [(u_{i+1,j} - u_{i-1,j})/2h] + O(h^2)$  (central difference), a second-order method. The second derivative is usually approximated with the second-order method  $[u_{xx}|_{i,j} = [(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})/h^2] + O(h^2)]$ .

**Example.** Using second-order differences for  $u_{xx}$  and  $u_{yy}$ , the five-point difference equation (with  $h = k$ ) for Laplace’s equation  $u_{xx} + u_{yy} = 0$  is  $u_{i,j} = 1/4[u_{i+1,j} + u_{i-1,j} + u_{i,j+1} + u_{i,j-1}]$ . The accuracy is  $O(h^2)$ . This model is called *implicit* because one must solve for the total number of unknowns at the unknown grid points  $(i, j)$  in terms of the given boundary data. In this case, the system of equations is a linear system.

**Example.** Using a forward-difference approximation for  $u_t$  and a second-order approximation for  $u_{xx}$ , the diffusion equation  $u_t = u_{xx}$  is approximated by the *explicit* formula  $u_{i,j+1} = ru_{i-1,j} + (1 - 2r)u_{i,j} + ru_{i+1,j}$ . This classic result permits step-by-step advancement in the  $t$  direction beginning with the initial data at  $t = 0$  ( $j = 0$ ) and guided by the boundary data. Here, the term  $r = \Delta t/(\Delta x)^2 = k/h^2$  is restricted to be less than or equal to  $1/2$  for stability and the truncation error is  $O(k^2 + kh^2)$ .

The Crank-Nicolson implicit formula which approximates the diffusion equation  $u_t = u_{xx}$  is

$$-r\lambda u_{i-1,j+1} + (1 + 2r\lambda)u_{i,j+1} - r\lambda u_{i+1,j+1} = r(1 - \lambda)u_{i-1,j} + [1 - 2r(1 - \lambda)]u_{i,j} + r(1 - \lambda)u_{i+1,j}$$

The stability of this numerical method was analyzed by Crandall (Ames, 1993) where the  $\lambda, r$  stability diagram is given.

Approximation of the time derivative in  $u_t = u_{xx}$  by a central difference leads to an always unstable approximation — the useless approximation

$$u_{i,j+1} = u_{i,j-1} + 2r(u_{i+1,j} - 2u_{i,j} + u_{i-1,j})$$

which is a warning to be careful.

The foregoing method is *symmetric* with respect to the point  $(i, j)$ , where the method is centered. Asymmetric methods have some computational advantages, so the Saul’yev method is described (Ames, 1993). The algorithms ( $r = k/h^2$ )

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i-1,j+1} - u_{i,j} + u_{i+1,j}) \quad (\text{Saul'yev A})$$

$$(1 + r)u_{i,j+1} = u_{i,j} + r(u_{i+1,j+1} - u_{i,j} + u_{i-1,j}) \quad (\text{Saul'yev B})$$

are used as in any one of the following options:

1. Use Saul’yev A only and proceed line-by-line in the  $t(j)$  direction, but *always* from the left boundary on a line.
2. Use Saul’yev B only and proceed line-by-line in the  $t(j)$  direction, but *always* from the right boundary to the left on a line.

3. Alternate from line to line by first using Saul'yev A and then B, or the reverse. This is related to *alternating direction methods*.
4. Use Saul'yev A and Saul'yev B on the same line and average the results for the final answer (A first, and then B). This is equivalent to introducing the dummy variables  $P_{ij}$  and  $Q_{ij}$  such that

$$(1+r)P_{i,j+1} = U_{i,j} + r(P_{i-1,j+1} - U_{i,j} + U_{i+1,j})$$

$$(1+r)Q_{i,j+1} = U_{i,j} + r(Q_{i+1,j+1} - U_{i,j} + U_{i-1,j})$$

and

$$U_{i,j+1} = \frac{1}{2}(P_{i,j+1} + Q_{i,j+1})$$

This averaging method has some computational advantage because of the possibility of truncation error cancellation. As an alternative, one can retain the  $P_{i,j}$  and  $Q_{i,j}$  from the previous step and replace  $U_{i,j}$  and  $U_{i+1,j}$  by  $P_{i,j}$  and  $P_{i+1,j}$ , respectively, and  $U_{i,j}$  and  $U_{i-1,j}$  by  $Q_{i,j}$  and  $Q_{i-1,j}$ , respectively.

### Weighted Residual Methods (WRMs)

To set the stage for the method of finite elements, we briefly describe the WRMs, which have several variations — the interior, boundary, and mixed methods. Suppose the equation is  $Lu = f$ , where  $L$  is the partial differential operator and  $f$  is a known function, of say  $x$  and  $y$ . The first step in WRM is to select a class of known basis functions  $b_i$  (e.g., trigonometric, Bessel, Legendre) to approximate  $u(x, y)$  as  $\sim \sum a_i b_i(x, y) = U(x, y, a)$ . Often, the  $b_i$  are selected so that  $U(x, y, a)$  satisfy the boundary conditions. This is essentially the *interior method*. If the  $b_i$  in  $U(x, y, a)$  are selected to satisfy the differential equations, but not the boundary conditions, the variant is called the *boundary method*. When neither the equation nor the boundary conditions are satisfied, the method is said to be *mixed*. The least ingenuity is required here. The usual method of choice is the interior method.

The second step is to select an optimal set of constants  $a_i$ ,  $i = 1, 2, \dots, n$ , by using the residual  $R_I(U) = LU - f$ . This is done here for the interior method. In the boundary method, there are a set of boundary residual  $R_B$ , and, in the mixed method. Both  $R_I$  and  $R_B$ . Using the spatial average  $(w, v) = \int_V wv dV$ , the criterion for selecting the values of  $a_i$  is the requirement that the  $n$  spatial averages

$$(b_i, R_E(U)) = 0, \quad i = 1, 2, \dots, n$$

These represent  $n$  equations (linear if the operator  $L$  is linear and nonlinear otherwise) for the  $a_i$ .

Particular WRMs differ because of the choice of the  $b_j$ s. The most common follow.

1. *Subdomain* The domain  $V$  is divided into  $n$  smaller, not necessarily disjoint, subdomains  $V_j$  with  $w_j(x, y) = 1$  if  $(x, y)$  is in  $V_j$ , and 0 if  $(x, y)$  is not in  $V_j$ .
2. *Collocation* Select  $n$  points  $P_j = (x_j, y_j)$  in  $V$  with  $w_j(P_j) = \delta(P - P_j)$ , where  $\int_V \phi(P) \delta(P - P_j) dP = \phi(P_j)$  for all test functions  $\phi(P)$  which vanish outside the compact set  $V$ . Thus,  $(w_j, R_E) = \int_V \delta(P - P_j) R_E dV = R_E[U(P_j)] \equiv 0$  (i.e., the residual is set equal to zero at the  $n$  points  $P_j$ ).
3. *Least squares* Here, the functional  $I(a) = \int_V R_E^2 dV$ , where  $a = (a_1, \dots, a_n)$ , is to be made stationary with respect to the  $a_j$ . Thus,  $0 = \partial I / \partial a_j = 2 \int_V R_E (\partial R_E / \partial a_j) dV$ , with  $j = 1, 2, \dots, n$ . The  $w_j$  in this case are  $\partial R_E / \partial a_j$ .
4. *Bubnov-Galerkin* Choose  $w_j(P) = b_j(P)$ . This is perhaps the best-known method.
5. *Stationary Functional (Variational) Method* With  $\phi$  a variational integral (or other functional), set  $\partial \phi[U] / \partial a_j = 0$ , where  $j = 1, \dots, n$ , to generate the  $n$  algebraic equations.

**Example.**  $u_{xx} + u_{yy} = -2$ , with  $u = 0$  on the boundaries of the square  $x = \pm 1, y = \pm 1$ . Select an interior method with  $U = a_1(1 - x^2)(1 - y^2) + a_2x^2y^2(1 - x^2)(1 - y^2)$ , whereupon the residual  $R_E(U) = 2a_1(2 - x^2 - y^2) + 2a_2[(1 - 6x^2)y^2(1 - y^2) + (1 - 6y^2)x^2(1 - x^2)] + 2$ . Collocating at  $(1/3, 1/3)$  and  $(2/3, 2/3)$  gives the two linear equations  $-32a_1/9 + 32a_2/243x^2 + 2 = 0$  and  $-20a_1/9 - 400a_2/243 + 2 = 0$  for  $a_1$  and  $a_2$ .

WRM methods can obviously be used as approximate methods. We have now set the stage for *finite elements*.

**Finite Elements**

The WRM methods are more general than the *finite elements* (FE) methods. FE methods require, in addition, that the basis functions be finite elements (i.e., functions that are zero except on a small part of the domain under consideration). A typical example of an often used basis is that of triangular elements. For a triangular element with Cartesian coordinates  $(x_1, y_1), (x_2, y_2)$ , and  $(x_3, y_3)$ , define natural coordinates  $L_1, L_2$ , and  $L_3$  ( $L_i \leftrightarrow (x_i, y_i)$ ) so that  $L_i = A_i/A$  where

$$A = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

is the area of the triangle and

$$A_1 = \frac{1}{2} \det \begin{bmatrix} 1 & x & y \\ 1 & x_2 & y_2 \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_2 = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x & y \\ 1 & x_3 & y_3 \end{bmatrix}$$

$$A_3 = \frac{1}{2} \det \begin{bmatrix} 1 & x_1 & y_1 \\ 1 & x_2 & y_2 \\ 1 & x & y \end{bmatrix}$$

Clearly  $L_1 + L_2 + L_3 = 1$ , and the  $L_i$  are one at node  $i$  and zero at the other nodes. In terms of the Cartesian coordinates,

$$\begin{bmatrix} L_1 \\ L_2 \\ L_3 \end{bmatrix} = \frac{1}{2A} \begin{bmatrix} x_2y_3 - x_3y_2, & y_2 - y_3, & x_3 - x_2 \\ x_3y_1 - x_1y_3, & y_3 - y_1, & x_1 - x_3 \\ x_1y_2 - x_2y_1, & y_1 - y_2, & x_2 - x_1 \end{bmatrix} \begin{bmatrix} 1 \\ x \\ y \end{bmatrix}$$

is the linear triangular element relation.

Tables of linear, quadratic, and cubic basis functions are given in the literature. Notice that while the linear basis needs three nodes, the quadratic requires six and the cubic basis ten. Various modifications, such as the Hermite basis, are described in the literature. Triangular elements are useful in approximating irregular domains.

For rectangular elements, the *chapeau* functions are often used. Let us illustrate with an example. Let  $u_{xx} + u_{yy} = Q, 0 < x < 2, 0 < y < 2, u(x, 2) = 1, u(0, y) = 1, u_y(x, 0) = 0, u_x(2, y) = 0$ , and  $Q(x, y) = Qw\delta(x - 1)\delta(y - 1)$ ,

$$\delta(x) = \begin{cases} 0 & x \neq 0 \\ 1 & x = 0 \end{cases}$$

Using four equal rectangular elements, map the element  $I$  with vertices at  $(0, 0)$ ,  $(0, 1)$ ,  $(1, 1)$ , and  $(1, 0)$  into the local (canonical) coordinates  $(\xi, \eta)$ ,  $-1 \leq \xi \leq 1$ ,  $-1 \leq \eta \leq 1$ , by means of  $x = 1/2(\xi + 1)$ ,  $y = 1/2(\eta + 1)$ . This mapping permits one to develop software that standardizes the treatment of all elements. Converting to  $(\xi, \eta)$  coordinates, our problem becomes  $u_{\xi\xi} + u_{\eta\eta} = 1/4Q$ ,  $-1 \leq \xi \leq 1$ ,  $-1 \leq \eta \leq 1$ ,  $Q = Qw\delta(\xi - 1)\delta(\eta - 1)$ .

First, a trial function  $\bar{u}(\xi, \eta)$  is defined as  $u(\xi, \eta) \approx \bar{\mu}(\xi, \eta) = \sum_{j=1}^4 A_j \phi_j(\xi, \eta)$  (in element  $I$ ) where the  $\phi_j$  are the two-dimensional chapeau functions

$$\begin{aligned} \phi_1 &= \left[\frac{1}{2}(1 - \xi)\frac{1}{2}(1 - \eta)\right] & \phi_2 &= \left[\frac{1}{2}(1 + \xi)\frac{1}{2}(1 - \eta)\right] \\ \phi_3 &= \left[\frac{1}{2}(1 + \xi)\frac{1}{2}(1 + \eta)\right] & \phi_4 &= \left[\frac{1}{2}(1 - \xi)\frac{1}{2}(1 + \eta)\right] \end{aligned}$$

Clearly  $\phi_i$  take the value one at node  $i$ , provide a bilinear approximation, and are nonzero only over elements adjacent to node  $i$ .

Second, the equation residual  $R_E = \nabla^2 \bar{u} - 1/4Q$  is formed and a WRM procedure is selected to formulate the algebraic equations for the  $A_i$ . This is indicated using the Galerkin method. Thus, for element  $I$ , we have

$$\iint_{D_I} (\bar{u}_{\xi\xi} + \bar{u}_{\eta\eta} - Q) \phi_i(\xi, \eta) d\xi d\eta = 0, \quad i = 1, \dots, 4$$

Applying Green's theorem, this result becomes

$$\iint_{D_I} \left[ \bar{u}_{\xi}(\phi_i)_{\xi} + \bar{u}_{\eta}(\phi_i)_{\eta} + \frac{1}{4}Q\phi_i \right] d\xi d\eta - \int_{\partial D_I} (\bar{u}_{\xi}c_{\xi} + \bar{u}_{\eta}c_{\eta}) \phi_i ds = 0, \quad i = 1, 2, \dots, 4$$

Using the same procedure in all four elements and recalling the property that the  $\phi_i$  in each element are nonzero only over elements adjacent to node  $i$  gives the following nine equations:

$$\begin{aligned} \sum_{e=1}^4 \left\{ \iint_{D_e} \sum_{j=1}^9 A_j \left[ (\phi_j)_{\xi}(\phi_i)_{\xi} + (\phi_j)_{\eta}(\phi_i)_{\eta} \right] + \frac{1}{4}Q\phi_i \right\} d\xi d\eta \\ - \sum_{e=1}^4 \int_{\partial D_e} (\bar{u}_{\xi}c_{\xi} + \bar{u}_{\eta}c_{\eta}) \phi ds = 0, \quad n = 1, 2, \dots, 9 \end{aligned}$$

where the  $c_{\xi}$  and  $c_{\eta}$  are the direction cosines of the appropriate element ( $e$ ) boundary.

### Method of Lines

The *method of lines*, when used on PDEs in two dimensions, reduces the PDE to a system of ordinary differential equations (ODEs), usually by finite difference or finite element techniques. If the original problem is an initial value (boundary value) problem, then the resulting ODEs form an initial value (boundary value) problem. These ODEs are solved by ODE numerical methods.

**Example.**  $u_t = u_{xx} + u^2$ ,  $0 < x < 1$ ,  $0 < t$ , with the initial value  $u(x, 0) = x$ , and boundary data  $u(0, t) = 0$ ,  $u(1, t) = \sin t$ . A discretization of the space variable ( $x$ ) is introduced and the time variable is left continuous. The approximation is  $\dot{u}_i = (u_{i+1} - 2u_i + u_{i-1})/h^2 + u_i^2$ . With  $h = 1/5$ , the equations become

$$\begin{aligned} u_0(t) &= 0 \\ \dot{u}_1 &= \frac{1}{25}[u_2 - 2u_1] + u_1^2 \\ \dot{u}_2 &= \frac{1}{25}[u_3 - 2u_2 + u_1] + u_2^2 \\ \dot{u}_3 &= \frac{1}{25}[u_4 - 2u_3 + u_2] + u_3^2 \\ \dot{u}_4 &= \frac{1}{25}[\sin t - 2u_4 + u_3] + u_4^2 \\ u_5 &= \sin t \end{aligned}$$

and  $u_1(0) = 0.2$ ,  $u_2(0) = 0.4$ ,  $u_3(0) = 0.6$ , and  $u_4(0) = 0.8$ .

### Discrete and Fast Fourier Transforms

Let  $x(n)$  be a sequence that is nonzero only for a finite number of samples in the interval  $0 \leq n \leq N - 1$ . The quantity

$$X(k) = \sum_{n=0}^{N-1} x(n)e^{-i(2\pi/N)nk}, \quad k = 0, 1, \dots, N - 1$$

is called the *discrete Fourier transform* (DFT) of the sequence  $x(n)$ . Its inverse (IDFT) is given by

$$x(n) = \frac{1}{N} \sum_{k=0}^{N-1} X(k)e^{i(2\pi/N)nk}, \quad n = 0, 1, \dots, N - 1 \quad (i^2 = -1)$$

Clearly, DFT and IDFT are finite sums and there are  $N$  frequency values. Also,  $X(k)$  is periodic in  $k$  with period  $N$ .

**Example.**  $x(0) = 1$ ,  $x(1) = 2$ ,  $x(2) = 3$ ,  $x(3) = 4$

$$X(k) = \sum_{n=0}^3 x(n)e^{-i(2\pi/4)nk}, \quad k = 0, 1, 2, 3, 4$$

Thus,

$$X(0) = \sum_{n=0}^3 x(n) = 10$$

and  $X(1) = x(0) + x(1)e^{-i\pi/2} + x(2)e^{-i\pi} + x(3)e^{-i3\pi/2} = 1 - 2i - 3 + 4i = -2 + 2i$ ;  $X(2) = -2$ ;  $X(3) = -2 - 2i$ .

### DFT Properties

1. Linearity: If  $x_3(n) = ax_1(n) + bx_2(n)$ , then  $X_3(k) = aX_1(k) + bX_2(k)$ .
2. Symmetry: For  $x(n)$  real,  $\text{Re}[X(k)] = \text{Re}[X(N - k)]$ ,  $\text{Im}[X(k)] = -\text{Im}[X(N - k)]$ .

3. Circular shift: By a circular shift of a sequence defined in the interval  $0 \leq n \leq N - 1$ , we mean that, as values *fall off* from one end of the sequence, they are appended to the other end. Denoting this by  $x(n \oplus m)$ , we see that positive  $m$  means shift left and negative  $m$  means shift right. Thus,  $x_2(n) = x_1(n \oplus m) \Leftrightarrow X_2(k) = X_1(k)e^{i(2\pi/N)km}$ .
4. Duality:  $x(n) \Leftrightarrow X(k)$  implies  $(1/N)X(n) \Leftrightarrow x(-k)$ .
5. Z-transform relation:  $X(k) = X(z)|_{z=e^{i(2\pi k/N)}}$ ,  $k = 0, 1, \dots, N - 1$ .
6. Circular convolution:  $x_3(n) = \sum_{m=0}^{N-1} x_1(m)x_2(n \ominus m) = \sum_{\ell=0}^{N-1} x_1(n \ominus \ell)x_2(\ell)$  where  $x_2(n \ominus m)$  corresponds to a circular shift to the right for positive  $m$ .

One fast algorithm for calculating DFTs is the radix-2 *fast Fourier transform* developed by J. W. Cooley and J. W. Tucker. Consider the two-point DFT  $X(k) = \sum_{n=0}^1 x(n)e^{-i(2\pi/2)nk}$ ,  $k = 0, 1$ . Clearly,  $X(k) = x(0) + x(1)e^{-i\pi k}$ . So,  $X(0) = x(0) + x(1)$  and  $X(1) = x(0) - x(1)$ . This process can be extended to DFTs of length  $N = 2^r$ , where  $r$  is a positive integer. For  $N = 2^r$ , decompose the  $N$ -point DFT into *two*  $N/2$ -point DFTs. Then, decompose each  $N/2$ -point DFT into *two*  $N/4$ -point DFTs, and so on until eventually we have  $N/2$  two-point DFTs. Computing these as indicated above, we combine them into  $N/4$  four-point DFTs and then  $N/8$  eight-point DFTs, and so on, until the DFT is computed. The total number of DFT operations (for large  $N$ ) is  $O(N^2)$ , and that of the FFT is  $O(N \log_2 N)$ , quite a saving for large  $N$ .

Figure 19.12.1

Figure 19.12.2

Figure 19.12.3

**FIGURES 19.12.1 to 19.12.3** The “Oregonator” is a periodic chemical reaction describable by three nonlinear first-order differential equations. The results (Figure 19.12.1) illustrate the periodic nature of the major chemical versus time. Figure 19.12.2 shows the phase diagram of two of the reactants, and Figure 19.12.3 is the three-dimensional phase diagram of all reactants. The numerical computation was done using a fourth-order Runge-Kuta method on Mathematica by Waltraud Rufeger at the Georgia Institute of Technology.

## Software

Some available software is listed here.

### General Packages

General software packages include Maple, Mathematica, and Matlab. All contain algorithms for handling a large variety of both numerical and symbolic computations.

### Special Packages for Linear Systems

In the IMSL Library, there are three complementary linear system packages of note.

LINPACK is a collection of programs concerned with *direct* methods for general (or full) symmetric, symmetric positive definite, triangular, and tridiagonal matrices. There are also programs for least squares problems, along with the QR algorithm for eigensystems and the singular value decompositions of rectangular matrices. The programs are intended to be completely machine independent, fully portable, and run with good efficiency in most computing environments. The LINPACK User's Guide by Dongarra *et al.* is the basic reference.

ITPACK is a modular set of programs for iterative methods. The package is oriented toward the sparse matrices that arise in the solution of PDEs and other applications. While the programs apply to full matrices, that is rarely profitable. Four basic iteration methods and two convergence acceleration methods are in the package. There is a Jacobi, SOR (with optimum relaxation parameter estimated), symmetric SOR, and reduced system (red-black ordering) iteration, each with semi-iteration and conjugate gradient acceleration. All parameters for these iterations are automatically estimated. The practical and theoretical background for ITPACK is found in Hagemen and Young (1981).

YALEPACK is a substantial collection of programs for sparse matrix computations.

### Ordinary Differential Equations Packages

Also in IMSL, one finds such sophisticated software as DVERK, DGEAR, or DREBS for initial value problems. For two-point boundary value problems, one finds DTPTB (use of DVERK and multiple shooting) or DVCPR.

### Partial Differential Equations Packages

DISPL was developed and written at Argonne National Laboratory. DISPL is designed for nonlinear second-order PDEs (parabolic, elliptic, hyperbolic (some cases), and parabolic-elliptic). Boundary conditions of a general nature and material interfaces are allowed. The spatial dimension can be either one or two and in Cartesian, cylindrical, or spherical (one dimension only) geometry. The PDEs are reduced to ordinary DEs by Galerkin discretization of the spatial variables. The resulting ordinary DEs in the timelike variable are then solved by an ODE software package (such as GEAR). Software features include graphics capabilities, printed output, dump/restart/facilities, and free format input. DISPL is intended to be an engineering and scientific tool and is not a finely tuned production code for a small set of problems. DISPL makes no effort to control the spatial discretization errors. It has been used to successfully solve a variety of problems in chemical transport, heat and mass transfer, pipe flow, etc.

PDELIB was developed and written at Los Alamos Scientific Laboratory. PDELIB is a library of subroutines to support the numerical solution of evolution equations with a timelike variable and one or two space variables. The routines are grouped into a dozen independent modules according to their function (i.e., accepting initial data, approximating spatial derivatives, advancing the solution in time). Each task is isolated in a distinct module. Within a module, the basic task is further refined into general-purpose flexible lower-level routines. PDELIB can be understood and used at different levels. Within a small period of time, a large class of problems can be solved by a novice. Moreover, it can provide a wide variety of outputs.

DSS/2 is a differential systems simulator developed at Lehigh University as a transportable numerical method of lines (NMOL) code. See also LEANS.

FORSIM is designed for the automated solution of sets of implicitly coupled PDEs of the form

$$\frac{\partial u_i}{\partial t} = \phi_i \left( x, t, u_i, u_j, \dots, (u_i)_x, \dots, (u_i)_{xx}, (u_j)_{xx}, \dots \right), \quad \text{for } i = 1, \dots, N$$

The user specifies the  $\phi_i$  in a simple FORTRAN subroutine. Finite difference formulas of any order may be selected for the spatial discretization and the spatial grid need not be equidistant. The resulting system of time-dependent ODEs is solved by the method of lines.

SLDGL is a program package for the self-adaptive solution of nonlinear systems of elliptic and parabolic PDEs in up to three space dimensions. Variable step size and variable order are permitted. The discretization error is estimated and used for the determination of the optimum grid and optimum orders. This is the most general of the codes described here (not for hyperbolic systems, of course). This package has seen extensive use in Europe.

FIDISOL (finite difference solver) is a program package for nonlinear systems of two- or three-dimensional elliptic and parabolic systems in rectangular domains or in domains that can be transformed analytically to rectangular domains. This package is actually a redesign of parts of SLDGL, primarily for the solution of large problems on vector computers. It has been tested on the CYBER 205, CRAY-IM, CRAY X-MP/22, and VP 200. The program vectorizes very well and uses the vector arithmetic efficiently. In addition to the numerical solution, a reliable error estimate is computed.

CAVE is a program package for conduction analysis via eigenvalues for three-dimensional geometries using the method of lines. In many problems, much time is saved because only a few terms suffice.

Many industrial and university computing services subscribe to the IMSL Software Library. Announcements of new software appear in *Directions*, a publication of IMSL. A brief description of some IMSL packages applicable to PDEs and associated problems is now given. In addition to those packages just described, two additional software packages bear mention. The first of these, the ELLPACK system, solves elliptic problems in two dimensions with general domains and in three dimensions with box-shaped domains. The system contains over 30 numerical methods modules, thereby providing a means of evaluating and comparing different methods for solving elliptic problems. ELLPACK has a special high-level language making it easy to use. New algorithms can be added or deleted from the system with ease.

Second, TWODEPEP is IMSL's general finite element system for two-dimensional elliptic, parabolic, and eigenvalue problems. The Galerkin finite elements available are triangles with quadratic, cubic, or quartic basic functions, with one edge curved when adjacent to a curved boundary, according to the isoparametric method. Nonlinear equations are solved by Newton's method, with the resulting linear system solved directly by Gauss elimination. PDE/PROTRAN is also available. It uses triangular elements with piecewise polynomials of degree 2, 3, or 4 to solve quite general steady state, time-dependent, and eigenvalue problems in general two-dimensional regions. There is a simple user input. Additional information may be obtained from IMSL. NASTRAN and STRUDL are two advanced finite element computer systems available from a variety of sources. Another, UNAFEM, has been extensively used.

## 19.13 Experimental Uncertainty Analysis

*W.G. Steele and H.W. Coleman*

### Introduction

The goal of an experiment is to answer a question by measuring a specific variable,  $X_r$ , or by determining a result,  $r$ , from a functional relationship among measured variables

$$r = r(X_1, X_2, \dots, X_i, \dots, X_j) \quad (19.13.1)$$

In all experiments there is some error that prevents the measurement of the true value of each variable, and therefore, prevents the determination of  $r_{\text{true}}$ .

Uncertainty analysis is a technique that is used to estimate the interval about a measured variable or a determined result within which the true value is thought to lie with a certain degree of confidence. As discussed by Coleman and Steele (1989), uncertainty analysis is an extremely useful tool for all phases of an experimental program from initial planning (general uncertainty analysis) to detailed design, debugging, test operation, and data analysis (detailed uncertainty analysis).

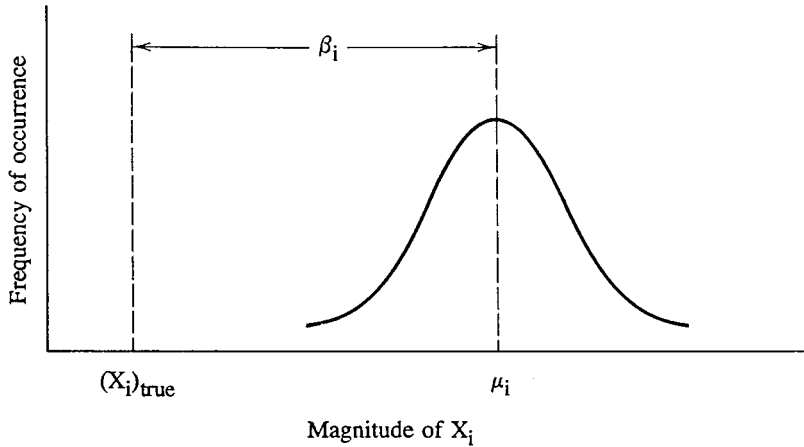

The application of uncertainty analysis in engineering has evolved considerably since the classic paper of Kline and McClintock (1953). Developments in the field have been especially rapid and significant over the past decade, with the methods formulated by Abernethy and co-workers (1985) that were incorporated into ANSI/ASME Standards in (1984) and (1986) being superseded by the more rigorous approach presented in the International Organization for Standardization (ISO) *Guide to the Expression of Uncertainty in Measurement* (1993). This guide, published in the name of ISO and six other international organizations, has in everything but name established a new international experimental uncertainty standard.

The approach in the ISO *Guide* deals with “Type A” and “Type B” categories of uncertainties, not the more traditional engineering categories of systematic (bias) and precision (random) uncertainties, and is of sufficient complexity that its application in normal engineering practice is unlikely. This issue has been addressed by AGARD Working Group 15 on Quality Assessment for Wind Tunnel Testing, by the Standards Subcommittee of the AIAA Ground Test Technical Committee, and by the ASME Committee PTC 19.1 that is revising the ANSI/ASME Standard (1986). The documents issued by two of these groups (AGARD-AR-304, 1994) and (AIAA Standard S-071-1995, 1995) and in preparation by the ASME Committee present and discuss the additional assumptions necessary to achieve a less complex “large sample” methodology that is consistent with the ISO *Guide*, that is applicable to the vast majority of engineering testing, including most single-sample tests, and that retains the use of the traditional engineering concepts of systematic and precision uncertainties. The range of validity of this “large sample” approximation has been presented by Steele et al. (1994) and by Coleman and Steele (1995). The authors of this section are also preparing a second edition of Coleman and Steele (1989), which will incorporate the ISO *Guide* methodology and will illustrate its use in all aspects of engineering experimentation.

In the following, the uncertainties of individual measured variables and of determined results are discussed. This section concludes with an overview of the use of uncertainty analysis in all phases of an experimental program.

### Uncertainty of a Measured Variable

For a measured variable,  $X_r$ , the total error is caused by both precision (random) and systematic (bias) errors. This relationship is shown in [Figure 19.13.1](#). The possible measurement values of the variable are scattered in a distribution (here assumed Gaussian) around the parent population mean,  $\mu_r$ . The parent population mean differs from  $(X_r)_{\text{true}}$  by an amount called the systematic (or bias) error,  $\beta_r$ . The quantity

**FIGURE 19.13.1** Errors in the measurement of variable  $X_i$ .

$\beta_i$  is the total fixed error that remains in the measurement process after all calibration corrections have been made. In general, there will be several sources of bias error such as calibration standard errors, data acquisition errors, data reduction errors, and test technique errors. There is usually no direct way to measure these errors, so they must be estimated.

For each bias error source,  $(\beta_i)_k$ , the experimenter must estimate a systematic uncertainty (or bias limit),  $(B_i)_k$ , such that there is about a 95% confidence that  $(B_i)_k \geq |(\beta_i)_k|$ . Systematic uncertainties are usually estimated from previous experience, calibration data, analytical models, and the application of sound engineering judgment. For each variable, there will be a set,  $K_i$ , of elemental systematic uncertainties,  $(B_i)_k$ , for the significant fixed error sources. The overall systematic uncertainty for variable  $X_i$  is determined from these estimates as

$$B_i^2 = \sum_{k=1}^{K_i} (B_i)_k^2 \tag{19.13.2}$$

For a discussion on estimating systematic uncertainties (bias limits), see Coleman and Steele (1989).

The estimate of the precision error for a variable is the sample standard deviation, or the estimate of the error associated with the repeatability of a particular measurement. Unlike the systematic error, the precision error varies from reading to reading. As the number of readings,  $N_i$ , of a particular variable tends to infinity, the distribution of these readings becomes Gaussian.

The readings used to calculate the sample standard deviation for each variable must be taken over the time frame and conditions which cover the variation in the variable. For example, taking multiple samples of data as a function of time while holding all other conditions constant will identify the random variation associated with the measurement system and the unsteadiness of the test condition. If the sample standard deviation of the variable being measured is also expected to be representative of other possible variations in the measurement, e.g., repeatability of test conditions, variation in test configuration, then these additional error sources will have to be varied while the multiple data samples are taken to determine the standard deviation.

When the value of a variable is determined as the mean,  $\bar{X}_i$ , of  $N_i$  readings, then the sample standard deviation of the mean is

$$S_{\bar{X}_i} = \left\{ \left[ \frac{1}{N_i(N_i - 1)} \right] \sum_{k=1}^{N_i} [(X_i)_k - \bar{X}_i]^2 \right\}^{1/2} \tag{19.13.3}$$

where

$$\bar{X}_i = \frac{\sum_{k=1}^{N_i} (X_i)_k}{N_i} \quad (19.13.4)$$

It must be stressed that these  $N_i$  readings have to be taken over the appropriate range of variations for  $X_i$  as described above.

When only a single reading of a variable is available so that the value used for the variable is  $X_i$ , then  $N_{P_i}$  previous readings,  $(X_{P_i})_k$ , must be used to find the standard deviation for the variable as

$$S_{X_i} = \left\{ \frac{1}{N_{P_i} - 1} \sum_{k=1}^{N_{P_i}} \left[ (X_{P_i})_k - \bar{X}_{P_i} \right]^2 \right\}^{1/2} \quad (19.13.5)$$

where

$$\bar{X}_{P_i} = \frac{1}{N_{P_i}} \sum_{k=1}^{N_{P_i}} (X_{P_i})_k \quad (19.13.6)$$

Another situation where previous readings of a variable are useful is when a small current sample size,  $N_i$ , is used to calculate the mean value,  $\bar{X}_i$ , of a variable. If a much larger set of previous readings for the same test conditions is available, then it can be used to calculate a more appropriate standard deviation for the variable (Steele et al., 1993) as

$$S_{\bar{X}_i} = \frac{S_{X_i}}{\sqrt{N_i}} \quad (19.13.7)$$

where  $N_i$  is the number of current readings averaged to determine  $\bar{X}_i$ , and  $S_{X_i}$  is computed from  $N_{P_i}$  previous readings using Equation (19.13.5). Typically, these larger data sets are taken in the early “shake-down” or “debugging” phases of an experimental program.

For many engineering applications, the “large sample” approximation applies, and the uncertainty for variable  $i$  ( $X_i$  or  $\bar{X}_i$ ) is

$$U_i = \sqrt{B_i^2 + (2S_i)^2} \quad (19.13.8)$$

where  $S_i$  is found from the applicable Equation (19.13.3), (19.13.5) or (19.13.7). The interval  $X_i \pm U_i$  or  $\bar{X}_i \pm U_i$ , as appropriate, should contain  $(X_i)_{\text{true}}$  95 times out of 100. If a small number of samples ( $N_i$  or  $N_{P_i} < 10$ ) is used to determine  $S_{\bar{X}_i}$  or  $S_{X_i}$ , then the “large sample” approximation may not apply and the methods in ISO (1993) or Coleman and Steele (1995) should be used to find  $U_i$ .

## Uncertainty of a Result

Consider an experimental result that is determined for  $J$  measured variables as

$$r = r(X_1, X_2, \dots, X_i, \dots, X_J)$$

where some variables may be single readings and others may be mean values. A typical mechanical engineering experiment would be the determination of the heat transfer in a heat exchanger as

$$q = \dot{m}c_p(T_o - T_i) \tag{19.13.9}$$

where  $q$  is the heat rate,  $\dot{m}$  is the flow rate,  $c_p$  is the fluid specific heat, and  $T_o$  and  $T_i$  are the heated fluid outlet and inlet temperatures, respectively. For the “large sample” approximation,  $U_r$  is found as

$$U_r = \sqrt{B_r^2 + (2S_r)^2} \tag{19.13.10}$$

where  $B_r$  is the systematic uncertainty of the result

$$B_r^2 = \sum_{i=1}^J (\theta_i B_i)^2 + 2 \sum_{i=1}^{J-1} \sum_{k=i+1}^J \theta_i \theta_k B_{ik} \tag{19.13.11}$$

with

$$\theta_i = \frac{\partial r}{\partial X_i} \tag{19.13.12}$$

and  $S_r$  is the standard deviation of the result

$$S_r^2 = \sum_{i=1}^J (\theta_i S_i)^2 \tag{19.13.13}$$

The term  $B_{ik}$  in Equation (19.13.11) is the covariance of the systematic uncertainties. When the elemental systematic uncertainties for two separately measured variables are related, for instance when the transducers used to measure different variables are each calibrated against the same standard, the systematic uncertainties are said to be correlated and the covariance of the systematic errors is nonzero. The significance of correlated systematic uncertainties is that they can have the effect of either decreasing or increasing the uncertainty in the result.  $B_{ik}$  is determined by summing the products of the elemental systematic uncertainties for variables  $i$  and  $k$  that arise from the same source and are therefore perfectly correlated (Brown et al., 1996) as

$$B_{ik} = \sum_{\alpha=1}^L (B_i)_\alpha (B_k)_\alpha \tag{19.13.14}$$

where  $L$  is the number of elemental systematic error sources that are common for measurements  $X_i$  and  $X_k$ .

If, for example,

$$r = r(X_1, X_2) \tag{19.13.15}$$

and it is possible for portions of the systematic uncertainties  $B_1$  and  $B_2$  to arise from the same source(s), Equation (19.13.11) gives

$$B_r^2 = \theta_1^2 B_1^2 + \theta_2^2 B_2^2 + 2\theta_1 \theta_2 B_{12} \tag{19.13.16}$$

For a case in which the measurements of  $X_1$  and  $X_2$  are each influenced by four elemental systematic error sources and sources two and three are the same for both  $X_1$  and  $X_2$ , Equation (19.13.2) gives

$$B_1^2 = (B_1)_1^2 + (B_1)_2^2 + (B_1)_3^2 + (B_1)_4^2 \quad (19.13.17)$$

and

$$B_2^2 = (B_2)_1^2 + (B_2)_2^2 + (B_2)_3^2 + (B_2)_4^2 \quad (19.13.18)$$

while Equation (19.13.14) gives

$$B_{12} = (B_1)_2 (B_2)_2 + (B_1)_3 (B_2)_3 \quad (19.13.19)$$

In the general case, there would be additional terms in the expression for the standard deviation of the result,  $S_r$ , (Equation 19.13.13) to take into account the possibility of precision errors in different variables being correlated. These terms have traditionally been neglected, although precision errors in different variables caused by the same uncontrolled factor(s) are certainly possible and can have a substantial impact on the value of  $S_r$  (Hudson et al., 1996). In such cases, one would need to acquire sufficient data to allow a valid estimate of the precision covariance terms using standard statistical techniques (ISO, 1993). Note, however, that if multiple test results over an appropriate time period are available, these can be used to directly determine  $S_r$ . This value of the standard deviation of the result implicitly includes the correlated error effect.

If a test is performed so that  $M$  multiple sets of measurements ( $X_1, X_2, \dots, X_J$ ) $_k$  at the same test condition are obtained, then  $M$  results can be determined using Equation (19.13.1) and a mean result,  $\bar{r}$ , can be determined using

$$\bar{r} = \frac{1}{M} \sum_{k=1}^M r_k \quad (19.13.20)$$

The standard deviation of the sample of  $M$  results,  $S_r$ , is calculated as

$$S_r = \left[ \frac{1}{M-1} \sum_{k=1}^M (r_k - \bar{r})^2 \right]^{1/2} \quad (19.13.21)$$

The uncertainty associated with the mean result,  $\bar{r}$ , for the “large sample” approximation is then

$$U_{\bar{r}} = \sqrt{B_r^2 + (2S_{\bar{r}})^2} \quad (19.13.22)$$

where

$$S_{\bar{r}} = \frac{S_r}{\sqrt{M}} \quad (19.13.23)$$

and where  $B_r$  is given by Equation (19.13.11).

The “large sample” approximation for the uncertainty of a determined result (Equations (19.13.10) or (19.13.22)) applies for most engineering applications even when some of the variables have fewer

than 10 samples. A detailed discussion of the applicability of this approximation is given in Steele et al. (1994) and Coleman and Steele (1995).

The determination of  $U_r$  from  $S_r$  (or  $S_{\bar{r}}$ ) and  $B_r$  using the “large sample” approximation is called detailed uncertainty analysis (Coleman and Steele, 1989). The interval  $r$  (or  $\bar{r}$ )  $\pm U_r$  (or  $U_{\bar{r}}$ ) should contain  $r_{\text{true}}$  95 times out of 100. As discussed in the next section, detailed uncertainty analysis is an extremely useful tool in an experimental program. However, in the early stages of the program, it is also useful to estimate the overall uncertainty for each variable,  $U_i$ . The overall uncertainty of the result is then determined as

$$U_r^2 = \sum_{k=1}^J (\theta_k U_i)^2 \quad (19.13.24)$$

This determination of  $U_r$  is called general uncertainty analysis.

## Using Uncertainty Analysis in Experimentation

The first item that should be considered in any experimental program is “What question are we trying to answer?” Another key item is how accurately do we need to know the answer, or what “degree of goodness” is required? With these two items specified, general uncertainty analysis can be used in the planning phase of an experiment to evaluate the possible uncertainties from the various approaches that might be used to answer the question being addressed. Critical measurements that will contribute most to the uncertainty of the result can also be identified.

Once past the planning, or preliminary design phase of the experiment, the effects of systematic errors and precision errors are considered separately using the techniques of detailed uncertainty analysis. In the design phase of the experiment, estimates are made of the systematic and precision uncertainties,  $B_r$  and  $2S_r$ , expected in the experimental result. These detailed design considerations guide the decisions made during the construction phase of the experiment.

After the test is constructed, a debugging phase is required before production tests are begun. In the debugging phase, multiple tests are run and the precision uncertainty determined from them is compared with the  $2S_r$  value estimated in the design phase. Also, a check is made to see if the test results plus and minus  $U_r$  compare favorably with known results for certain ranges of operation. If these checks are not successful, then further test design, construction, and debugging is required.

Once the test operation is fully understood, the execution phase can begin. In this phase, balance checks can be used to monitor the operation of the test apparatus. In a balance check, a quantity, such as flow rate, is determined by different means and the difference in the two determinations,  $z$ , is compared to the ideal value of zero. For the balance check to be satisfied, the quantity  $z$  must be less than or equal to  $U_z$ .

Uncertainty analysis will of course play a key role in the data analysis and reporting phases of an experiment. When the experimental results are reported, the uncertainties should be given along with the systematic uncertainty,  $B_r$ , the precision uncertainty,  $2S_r$ , and the associated confidence level, usually 95%.

## 19.14 Chaos

*R. L. Kautz*

### Introduction

Since the time of Newton, the science of dynamics has provided quantitative descriptions of regular motion, from a pendulum's swing to a planet's orbit, expressed in terms of differential equations. However, the role of Newtonian mechanics has recently expanded with the realization that it can also describe chaotic motion. In elementary terms, **chaos** can be defined as **pseudorandom** behavior observed in the steady-state dynamics of a deterministic **nonlinear system**. How can motion be pseudorandom, or random according to statistical tests and yet be entirely predictable? This is just one of the paradoxes of chaotic motion, which is globally stable but locally unstable, predictable in principle but not in practice, and geometrically complex but derived from simple equations.

The strange nature of chaotic motion was first understood by Henri Poincaré, who established the mathematical foundations of chaos in a treatise published in 1890 (Holmes, 1990). However, the practical importance of chaos began to be widely appreciated only in the 1960s, beginning with the work of Edward Lorenz (1963), a meteorologist who discovered chaos in a simple model for fluid convection. Today, chaos is understood to explain a wide variety of apparently random natural phenomena, ranging from dripping faucets (Martien et al., 1985), to the flutter of a falling leaf (Tanabe and Kaneko, 1994), to the irregular rotation of a moon of Saturn (Wisdom et al., 1984).

Although chaos is used purposely to provide an element of unpredictability in some toys and carnival rides (Kautz and Huggard, 1994), it is important from an engineering point of view primarily as a phenomenon to be avoided. Perhaps the simplest scenario arises when a nonlinear mechanism is used to achieve a desired effect, such as the synchronization of two oscillators. In many such cases, the degree of nonlinearity must be chosen carefully: strong enough to ensure the desired effect but not so strong that chaos results. In another scenario, an engineer might be required to deal with an intrinsically chaotic system. In this case, if the system can be modeled mathematically, then a small feedback signal can often be applied to eliminate the chaos (Ott et al., 1990). For example, low-energy feedback has been used to suppress chaotic behavior in a thermal convection loop (Singer et al., 1991). As such considerations suggest, chaos is rapidly becoming an important topic for engineers.

### Flows, Attractors, and Liapunov Exponents

Dynamic systems can generally be described mathematically in terms of a set of differential equations of the form.

$$d\mathbf{x}(t)/dt = \mathbf{F}[\mathbf{x}(t)] \quad (19.14.1)$$

where  $\mathbf{x} = (x_1, \dots, x_N)$  is an  $N$ -dimensional vector called the **state vector** and the vector function  $\mathbf{F} = F_1(\mathbf{x}), \dots, F_N(\mathbf{x})$  defines how the state vector changes with time. In mechanics, the state variables  $x_i$  are typically the positions and velocities associated with the potential and kinetic energies of the system. Because the state vector at times  $t > 0$  depends only on the initial state vector  $\mathbf{x}(0)$ , the system defined by Equation (19.14.1) is deterministic, and its motion is in principle exactly predictable.

The properties of a dynamic system are often visualized most readily in terms of trajectories  $\mathbf{x}(t)$  plotted in **state space**, where points are defined by the coordinates  $(x_1, \dots, x_N)$ . As an example, consider the motion of a damped pendulum defined by the normalized equation

$$d^2\theta/dt^2 = -\sin\theta - \rho d\theta/dt \quad (19.14.2)$$

which expresses the angular acceleration  $d^2\theta/dt^2$  in terms of the gravitational torque  $-\sin \theta$  and a damping torque  $-\rho d\theta/dt$  proportional to the angular velocity  $v = d\theta/dt$ . If we define the state vector as  $\mathbf{x} = (x_1, x_2) = (\theta, v)$ , then Equation (19.14.2) can be written in the form of Equation (19.14.1) with  $\mathbf{F} = (x_2, -\sin x_1 - \rho x_2)$ . In this case, the state space is two dimensional, and a typical trajectory is a spiral, as shown in Figure 19.14.1 for the initial condition  $\mathbf{x}(0) = (0, 1)$ . If additional trajectories, corresponding to other initial conditions, were plotted in Figure 19.14.1, we would obtain a set of interleaved spirals, all converging on the point  $\mathbf{x} = (0, 0)$ . Because the direction of a trajectory passing through a given point is uniquely defined by Equation (19.14.1), state-space trajectories can never cross, and, by analogy with the motion of a fluid, the set of all of trajectories is called a flow.

**FIGURE 19.14.1** The state-space trajectory  $\mathbf{x}(t)$  for a pendulum with a damping coefficient  $\rho = 0.2$  for the initial condition  $\mathbf{x}(0) = (0, 1)$ . The evolution of trajectories initialized in a small circle surrounding  $\mathbf{x} = (0, 1)$  is indicated by the ellipses plotted at time intervals of  $\Delta t = 1.5$ .

The tendency of a flow to converge toward a single point or other restricted subset of state space is characteristic of dissipative systems like the damped pendulum. Such an asymptotic set, called an attracting set or **attractor**, can be a fixed point (for which  $\mathbf{F}(\mathbf{x}) = 0$ ) as in Figure 19.14.1, but might also be a periodic or chaotic trajectory. The convergence of neighboring trajectories is suggested in Figure 19.14.1 by a series of ellipses spaced at time intervals  $\Delta t = 1.5$  that track the flow of all trajectories originating within the circle specified at  $t = 0$ . In general, the contraction of an infinitesimal state-space volume  $V$  as it moves with the flow is given by

$$V^{-1} \partial V / \partial t = \nabla \cdot \mathbf{F} \tag{19.14.3}$$

where  $\nabla \cdot \mathbf{F} = \sum_{i=1}^N \partial F_i / x_i$  is the divergence of  $\mathbf{F}$ . For the damped pendulum,  $\nabla \cdot \mathbf{F} = \rho$ , so the area of the ellipse shown in Figure 19.14.1 shrinks exponentially as  $V(t) = V(0) \exp(-\rho t)$ . The contraction of state-space volumes explains the existence of attractors in dissipative systems, but in conservative systems such as the pendulum with  $\rho = 0$ , state-space volumes are preserved, and trajectories are instead confined to constant-energy surfaces.

While the existence of chaotic behavior is generally difficult to predict, two essential conditions are easily stated. First, the complex topology of a chaotic trajectory can exist only in a state-space of dimension  $N \geq 3$ . Thus, the pendulum defined by Equation (19.14.2) cannot be chaotic because  $N = 2$  for this system. Second, a system must be nonlinear to exhibit chaotic behavior. Linear systems, for which any linear combination  $c_1 x_a(t) + c_2 x_b(t)$  of two solutions  $x_a(t)$  and  $x_b(t)$  is also a solution, are mathematically simple and amenable to analysis. In contrast, nonlinear systems are noted for their

**FIGURE 19.14.2** A trajectory  $\mathbf{x}(t)$  and a neighboring trajectory  $\tilde{\mathbf{x}}(t)$  plotted in state space from time  $t_0$  to  $t_1$ . The vectors  $\mathbf{e}(t_0)$  and  $\mathbf{e}(t_1)$  indicate the deviation of  $\tilde{\mathbf{x}}(t)$  from  $\mathbf{x}(t)$  at times  $t_0$  and  $t_1$ .

intractability. Thus, chaotic behavior is of necessity explored more frequently by numerical simulation than mathematical analysis, a fact that helps explain why the prevalence of chaos was discovered only after the advent of efficient computation.

A useful criterion for the existence of chaos can be developed from an analysis of a trajectory’s local stability. As sketched in [Figure 19.14.2](#), the local stability of a trajectory  $\mathbf{x}(t)$  is determined by considering a neighboring trajectory  $\tilde{\mathbf{x}}(t)$  initiated by an infinitesimal deviation  $\mathbf{e}(t_0)$  from  $\mathbf{x}(t)$  at time  $t_0$ . The deviation vector  $\mathbf{e}(t) = \tilde{\mathbf{x}}(t) - \mathbf{x}(t)$  at times  $t_1 > t_0$  can be expressed in terms of the Jacobian matrix

$$J_{ij}(t_1, t_0) = \partial x_i(t_1) / \partial x_j(t_0) \tag{19.14.4}$$

which measures the change in state variable  $x_i$  at time  $t_1$  due to a change in  $x_j$  at time  $t_0$ . From the Jacobian’s definition, we have  $\mathbf{e}(t_1) = \mathbf{J}(t_1, t_0)\mathbf{e}(t_0)$ . Although the local stability of  $\mathbf{x}(t)$  is determined simply by whether deviations grow or decay in time, the analysis is complicated by the fact that deviation vectors can also rotate, as suggested in [Figure 19.14.2](#). Fortunately, an arbitrary deviation can be written in terms of the eigenvectors  $\mathbf{e}^{(i)}$  of the Jacobian, defined by

$$\mathbf{J}(t_1, t_0)\mathbf{e}^{(i)} = \mu_i(t_1, t_0)\mathbf{e}^{(i)} \tag{19.14.5}$$

which are simply scaled by the eigenvalues  $\mu_i(t_1, t_0)$  without rotation. Thus, the  $N$  eigenvalues of the Jacobian matrix provide complete information about the growth of deviations. Anticipating that the asymptotic growth will be exponential in time, we define the **Liapunov exponents**,

$$\lambda_i = \lim_{t_1 \rightarrow \infty} \frac{\ln|\mu_i(t_1, t_0)|}{t_1 - t_0} \tag{19.14.6}$$

Because any deviation can be broken into components that grow or decay asymptotically as  $\exp(\lambda_i t)$ , the  $N$  exponents associated with a trajectory determine its local stability.

In dissipative systems, chaos can be defined as motion on an attractor for which one or more Liapunov exponents are positive. Chaotic motion thus combines global stability with local instability in that motion is confined to the attractor, generally a bounded region of state space, but small deviations grow exponentially in time. This mixture of stability and instability in chaotic motion is evident in the behavior of an infinitesimal deviation ellipsoid similar to the finite ellipse shown in [Figure 19.14.1](#). Because some  $\lambda_i$  are positive, an ellipsoid centered on a chaotic trajectory will expand exponentially in some directions. On the other hand, because state-space volumes always contract in dissipative systems and the asymptotic volume of the ellipsoid scales as  $\exp(\Lambda t)$ , where  $\Lambda = \sum_{i=1}^N \lambda_i$ , the sum of the negative exponents must be greater in magnitude than the sum of the positive exponents. Thus, a deviation ellipsoid tracking a

chaotic trajectory expands in some directions while contracting in others. However, because an arbitrary deviation almost always includes a component in a direction of expansion, nearly all trajectories neighboring a chaotic trajectory diverge exponentially.

According to our definition of chaos, neighboring trajectories must diverge exponentially and yet remain on the attractor. How is this possible? Given that the attractor is confined to a bounded region of state space, perpetual divergence can occur only for trajectories that differ infinitesimally. Finite deviations grow exponentially at first but are limited by the bounds of the chaotic attractor and eventually shrink again. The full picture can be understood by following the evolution of a small state-space volume selected in the neighborhood of the chaotic attractor. Initially, the volume expands in some directions and contracts in others. When the expansion becomes too great, however, the volume begins to fold back on itself so that trajectories initially separated by the expansion are brought close together again. As time passes, this stretching and folding is repeated over and over in a process that is often likened to kneading bread or pulling taffy.

Because all neighboring volumes approach the attractor, the stretching and folding process leads to an attracting set that is an infinitely complex filigree of interleaved surfaces. Thus, while the differential equation that defines chaotic motion can be very simple, the resulting attractor is highly complex. Chaotic attractors fall into a class of geometric objects called **fractals**, which are characterized by the presence of structure at arbitrarily small scales and by a dimension that is generally fractional. While the existence of objects with dimensions falling between those of a point and a line, a line and a surface, or a surface and a volume may seem mysterious, fractional dimensions result when dimension is defined by how much of an object is apparent at various scales of resolution. For the dynamical systems encompassed by Equation (19.14.1), the fractal dimension  $D$  of a chaotic attractor falls in the range of  $2 < D < N$  where  $N$  is the dimension of the state space. Thus, the dimension of a chaotic attractor is large enough that trajectories can continually explore new territory within a bounded region of state space but small enough that the attractor occupies no volume of the space.

## Synchronous Motor

As an example of a system that exhibits chaos, we consider a simple model for a synchronous motor that might be used in a clock. As shown in Figure 19.14.3, the motor consists of a permanent-magnet rotor subjected to a uniform oscillatory magnetic field  $B \sin t$  provided by the stator. In dimensionless notation, its equation of motion is

$$d^2\theta/dt^2 = -f \sin t \sin \theta - \rho d\theta/dt \quad (19.14.7)$$

where  $d^2\theta/dt^2$  is the angular acceleration of the rotor,  $-f \sin t \sin \theta$  is the torque due to the interaction of the rotor's magnetic moment with the stator field, and  $-\rho d\theta/dt$  is a viscous damping torque. Although Equation (19.14.7) is explicitly time dependent, it can be cast in the form of Equation (19.14.1) by

**FIGURE 19.14.3** A synchronous motor, consisting of a permanent magnet free to rotate in a uniform magnetic field  $B \sin t$  with an amplitude that varies sinusoidally in time.

defining the state vector as  $\mathbf{x} = (x_1, x_2, x_3) = (\theta, v, t)$ , where  $v = d\theta/dt$  is the angular velocity, and by defining the flow as  $\mathbf{F} = (x_2, -f \sin x_3 \sin x_1 - \rho x_2, 1)$ . The state space is thus three dimensional and large enough to allow chaotic motion. Equation (19.14.7) is also nonlinear due to the term  $-f \sin t \sin \theta$ , since  $\sin(\theta_a + \theta_b)$  is not generally equal to  $\sin \theta_a + \sin \theta_b$ . Chaos in this system has been investigated by several authors (Ballico et al., 1990).

By intent, the motor uses nonlinearity to synchronize the motion of the rotor with the oscillatory stator field, so it evolves exactly once during each field oscillation. Although synchronization can occur over a range of system parameters, proper operation requires that the drive amplitude  $f$ , which measures the strength of the nonlinearity, be chosen large enough to produce the desired rotation but not so large that chaos results. Calculating the motor's dynamics for  $\rho = 0.2$ , we find that the rotor oscillates without rotating for  $f$  less than 0.40 and that the intended rotation is obtained for  $0.40 < \rho < 1.87$ . The periodic attractor corresponding to synchronized rotation is shown for  $f = 1$  in Figure 19.14.4(a). Here the three-dimensional state-space trajectory is projected onto the  $(x_1, x_2)$  or  $(\theta, v)$  plane, and a dot marks the point in the rotation cycle at which  $t = 0$  modulo  $2\pi$ . As Figure 19.14.4(a) indicates, the rotor advances by exactly  $2\pi$  during each drive cycle.

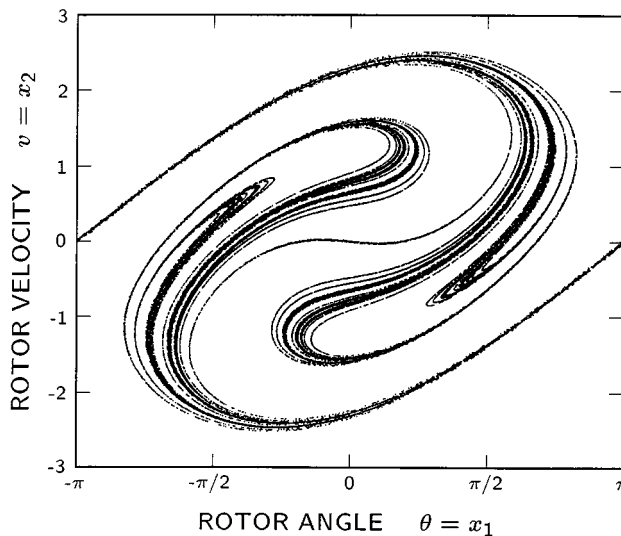

**FIGURE 19.14.4** State-space trajectories projected onto the  $(x_1, x_2)$  or  $(\theta, v)$  plane, showing attractors of the synchronous motor for  $\rho = 0.2$  and two drive amplitudes,  $f = 1$  and 3. Dots mark the state of the system at the beginning of each drive cycle ( $t = 0$  modulo  $2\pi$ ). The angles  $\theta = \pi$  and  $-\pi$  are equivalent.

The utility of the motor hinges on the stability of the synchronous rotation pattern shown in Figure 19.14.4(a). This periodic pattern is the steady-state motion that develops after initial transients decay and represents the final asymptotic trajectory resulting for initial conditions chosen from a wide area of state space. Because the flow approaches this attracting set from all neighboring points, the effect of a perturbation that displaces the system from the attractor is short lived. This stability is reflected in the Liapunov exponents of the attractor:  $\lambda_1 = 0$  and  $\lambda_2 = \lambda_3 = -0.100$ . The zero exponent is associated with deviations coincident with the direction of the trajectory and is a feature common to all bounded attractors

other than fixed points. The zero exponent results because the system is neutrally stable with respect to offsets in the time coordinate. The exponents of  $-0.100$  are associated with deviations transverse to the trajectory and indicate that these deviations decay exponentially with a characteristic time of 1.6 drive cycles. The negative exponents imply that the synchrony between the rotor and the field is maintained in spite of noise or small variations in system parameters, as required of a clock motor.

For drive amplitudes greater than  $f = 1.87$ , the rotor generally does not advance by precisely  $2\pi$  during every drive cycle, and its motion is commonly chaotic. An example of chaotic behavior is illustrated for  $f = 3$  by the trajectory plotted in Figure 19.14.4(b) over an interval of 10 drive cycles. In this figure, sequentially numbered dots mark the beginning of each drive cycle. When considered cycle by cycle, the trajectory proves to be a haphazard sequence of oscillations, forward rotations, and reverse rotations. Although we might suppose that this motion is just an initial transient, it is instead characteristic of the steady-state behavior of the motor. If extended, the trajectory continued with an apparently random mixture of oscillation and rotation, without approaching a repetitive cycle. The motion is aptly described as chaotic.

The geometry of the chaotic attractor sampled in Figure 19.14.4(b) is revealed more fully in Figure 19.14.5. Here we plot points  $(\theta, v)$  recording the instantaneous angle and velocity of the rotor at the beginning of each drive cycle for 100,000 successive cycles, Figure 19.14.5 displays the three-dimensional attractor called a **Poincaré section**, at its intersection with the planes  $t = x_3 = 0$  modulo  $2\pi$ , corresponding to equivalent times in the drive cycle. For the periodic attractor of Figure 19.14.4(a), the rotor returns to the same position and velocity at the beginning of each drive cycle, so its Poincaré section is a single point, the dot in this figure. For chaotic motion, in contrast, we obtain the complex swirl of points shown in Figure 19.14.5. If the system is initialized at a point far from the swirl, the motion quickly converges to this attracting set. On succeeding drive cycles, the state of the system jumps from one part of the swirl to another in an apparently random fashion that continues indefinitely. As the number of plotted points approaches infinity, the swirl becomes a cross section of the chaotic attractor. Thus, Figure 19.14.5 approximates a slice through the infinite filigree of interleaved surfaces that compose the attracting set. In this case, the fractal dimension of the attractor is 2.52 and that of its Poincaré section is 1.52.

**FIGURE 19.14.5** Poincaré section of a chaotic attractor of the synchronous motor with  $p = 0.2$  and  $f = 3$ , obtained by plotting points  $(x_1, x_2) = (\theta, v)$  corresponding to the position and velocity of the rotor at the beginning of 100,000 successive drive cycles.

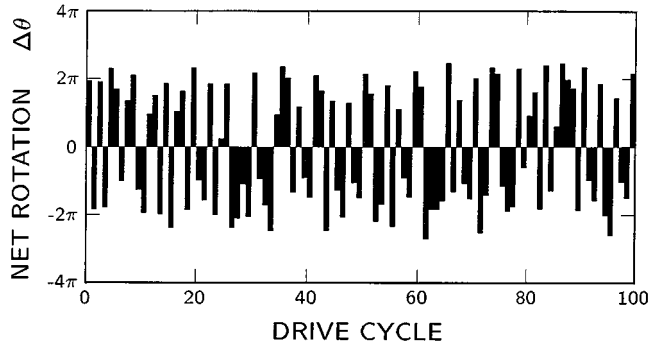

The computed Liapunov exponents of the chaotic solution at  $p = 0.2$  and  $f = 3$  are  $\lambda_1 = 0$ ,  $\lambda_2 = 0.213$ , and  $\lambda_3 = -0.413$ . As for the periodic solution, the zero exponent implies neutral stability associated with deviations directed along a given trajectory. The positive exponent, which signifies the presence of chaos, is associated with deviations transverse to the given trajectory but tangent to the surface of the attracting set in which it is embedded. The positive exponent implies that such deviations grow exponentially in time and that neighboring trajectories on the chaotic attractor diverge exponentially, a property characteristic of chaotic motion. The negative exponent is associated with deviations transverse to the surface of the attractor and assures the exponential decay of displacements from the attracting set. Thus, the Liapunov exponents reflect both the stability of the chaotic attractor and the instability of a given chaotic trajectory with respect to neighboring trajectories.

One sequence of a positive Liapunov exponent is a practical limitation on our ability to predict the future state of a chaotic system. This limitation is illustrated in Figure 19.14.6, where we plot a given chaotic trajectory (solid line) and three perturbed trajectories (dashed lines) that result by offsetting the initial phase of the given solution by various deviations  $e_1(0)$ . When the initial angular offset is  $e_1(0) = 10^{-3}$  radian, the perturbed trajectory (short dash) closely tracks the given trajectory for about seven drive cycles before the deviation become significant. After seven drive cycles, the perturbed trajectory is virtually independent of the given trajectory, even though it is confined to the same attractor. Similarly, initial offsets of  $10^{-6}$  and  $10^{-9}$  radian lead to perturbed trajectories (medium and long dash) that track the given trajectory for about 12 and 17 drive cycles, respectively, before deviations become significant. These results reflect the fact that small deviations grow exponentially and, in the present case, increase on average by a factor of 10 every 1.7 drive cycles. If the position of the rotor is to be predicted with an accuracy of  $10^{-1}$  radian after 20 drive cycles, its initial angle must be known to better than  $10^{-13}$  radian, and the calculation must be carried out with at least 14 significant digits. If a similar prediction is to be made over 40 drive cycles, then 25 significant digits are required. Thus, even though chaotic motion is predictable in principle, the state of a chaotic system can be accurately predicted in practice for only a short time into the future. According to Lorenz (1993), this effect explains why weather forecasts are of limited significance beyond a few days.

**FIGURE 19.14.6** Rotor angle as a function of time for chaotic trajectories of the synchronous motor with  $p = 0.2$  and  $f = 3$ . Solid line shows a given trajectory and dashed lines show perturbed trajectories resulting from initial angular deviations of  $e_1(0) = 10^{-3}$  (short dash),  $10^{-6}$  (medium dash), and  $10^{-9}$  (long dash).

This pseudorandom nature of chaotic motion is illustrated in Figure 19.14.7 for the synchronous motor by a plot of the net rotation during each of 100 successive drive cycles. Although this sequence of rotations results from solving a deterministic equation, it is apparently random, jumping erratically between forward and reverse rotations of various magnitudes up to about 1.3 revolutions. The situation

**FIGURE 19.14.7** Net rotation of a synchronous motor during each of 100 successive drive cycles, illustrating chaotic motion for  $\rho = 0.2$  and  $f = 3$ . By definition,  $\Delta\theta = \theta(2\pi n) - \theta(2\pi(n-1))$  on the  $n$ th drive cycle.

is similar to that of a digital random number generator, in which a deterministic algorithm is used to produce a sequence of pseudorandom numbers. In fact, the similarity is not coincidental since chaotic processes often underlie such algorithms (Li, 1978). For the synchronous motor, statistical analysis reveals almost no correlation between rotations separated by more than a few drive cycles. This statistical independence is a result of the motor's positive Liapunov exponent. Because neighboring trajectories diverge exponentially, a small region of the attractor can quickly expand to cover the entire attractor, and a small range of rotations on one drive cycle can lead to almost any possible rotation a few cycles later. Thus, there is little correlation between rotations separated by a few drive cycles, and on this time scale the motor appears to select randomly between the possible rotations.

From an engineering point of view, the problem of chaotic behavior in the synchronous motor can be solved simply by selecting a drive amplitude in the range of  $0.40 < f < 1.87$ . Within this range, the strength of the nonlinearity is large enough to produce synchronization but not so large as to produce chaos. As this example suggests, it is important to recognize that erratic, apparently random motion can be an intrinsic property of a dynamic system and is not necessarily a product of external noise. Searching a real motor for a source of noise to explain the behavior shown in Figure 19.14.7 would be wasted effort since the cause is hidden in a noise-free differential equation. Clearly, chaotic motion is a possibility that every engineer should understand.

## Defining Terms

**Attractor:** A set of points in state space to which neighboring trajectories converge in the limit of large time.

**Chaos:** Pseudorandom behavior observed in the steady-state dynamics of a deterministic nonlinear system.

**Fractal:** A geometric object characterized by the presence of structure at arbitrarily small scales and by a dimension that is generally fractional.

**Liapunov exponent:** One of  $N$  constants  $\lambda_i$  that characterize the asymptotic exponential growth of infinitesimal deviations from a trajectory in an  $N$ -dimensional state space. Various components of a deviation grow or decay on average in proportion to  $\exp(\lambda_i t)$ .

**Nonlinear system:** A system of equations for which a linear combination of two solutions is not generally a solution.

**Poincaré section:** A cross section of a state-space trajectory formed by the intersection of the trajectory with a plane defined by a specified value of one state variable.

**Pseudorandom:** Random according to statistical tests but derived from a deterministic process.

**State space:** The space spanned by state vectors.

State vector: A vector  $\mathbf{x}$  whose components are the variables, generally positions and velocities, that define the time evolution of a dynamical system through an equation of the form  $\dot{x}/dt = \mathbf{F}(\mathbf{x})$ , where  $\mathbf{F}$  is a vector function.

## For Further Information

- A good introduction to deterministic chaos for undergraduates is provided by *Chaotic and Fractal Dynamics: An Introduction for Applied Scientists and Engineers* by Francis C. Moon. This book presents numerous examples drawn from mechanical and electrical engineering.
- Chaos in Dynamical Systems* by Edward Ott provides a more rigorous introduction to chaotic dynamics at the graduate level.
- Practical methods for experimental analysis and control of chaotic systems are presented in *Coping with Chaos: Analysis of Chaotic Data and the Exploitation of Chaotic Systems*, a reprint volume edited by Edward Ott, Tim Sauer, and James A. York.

## 19.15 Fuzzy Sets and Fuzzy Logic

*Dan M. Frangopol*

### Introduction

In the sixties, Zaheh (1965) introduced the concept of fuzzy sets. Since its inception more than 30 years ago, the theory and methods of fuzzy sets have developed considerably. The demands for treating situations in engineering, social sciences, and medicine, among other applications that are complex and not crisp have been strong driving forces behind these developments.

The concept of the fuzzy set is a generalization of the concept of the ordinary (or crisp) set. It introduces vagueness by eliminating the clear boundary, defined by the ordinary set theory, between full nonmembers (i.e., grade of membership equals zero) and full members (i.e., grade of membership equals one). According to Zaheh (1965) a fuzzy set  $A$ , defined as a collection of elements (also called objects)  $x \in X$ , where  $X$  denotes the universal set (also called universe of discourse) and the symbol  $\in$  denotes that the element  $x$  is a member of  $X$ , is characterized by a membership (also called characteristic) function  $\mu_A(x)$  which associates each point in  $X$  a real member in the unit interval  $[0,1]$ . The value of  $\mu_A(x)$  at  $x$  represents the grade of membership of  $x$  in  $A$ . Larger values of  $\mu_A(x)$  denote higher grades of membership of  $x$  in  $A$ . For example, a fuzzy set representing the concept of control might assign a degree of membership of 0.0 for no control, 0.1 for weak control, 0.5 for moderate control, 0.9 for strong control, and 1.0 for full control. From this example, it is clear that the two-valued crisp set [i.e., no control (grade of membership 0.0) and full control (grade of membership 1.0)] is a particular case of the general multivalued fuzzy set  $A$  in which  $\mu_A(x)$  takes its values in the interval  $[0,1]$ .

Problems in engineering could be very complex and involve various concepts of uncertainty. The use of fuzzy sets in engineering has been quite extensive during this decade. The area of fuzzy control is one of the most developed applications of fuzzy set theory in engineering (Klir and Folger, 1988). Fuzzy controllers have been created for the control of robots, aircraft autopilots, and industrial processes, among others. In Japan, for example, so-called “fuzzy electric appliances,” have gained great success from both technological and commercial points of view (Furuta, 1995). Efforts are underway to develop and introduce fuzzy sets as a technical basis for solving various real-world engineering problems in which the underlying information is complex and imprecise. In order to achieve this, a mathematical background in the theory of fuzzy sets is necessary. A brief summary of the fundamental mathematical aspects of the theory of fuzzy sets is presented herein.

### Fundamental Notions

A fuzzy set  $A$  is represented by all its elements  $x_i$  and associated grades of membership  $\mu_A(x_i)$  (Klir and Folger, 1988).

$$A = \left\{ \mu_A(x_1)|_{x_1}, \mu_A(x_2)|_{x_2}, \dots, \mu_A(x_n)|_{x_n} \right\} \quad (19.15.1)$$

where  $x_i$  is an element of the fuzzy set,  $\mu_A(x_i)$  is its grade of membership in  $A$ , and the vertical bar is employed to link the element with their grades of membership in  $A$ . Equation (19.15.1) shows a discrete form of a fuzzy set. For a continuous fuzzy set, the membership function  $\mu_A(x)$  is a continuous function of  $x$ .

Figure 19.15.1 illustrates a discrete and a continuous fuzzy set. The larger membership grade  $\max(\mu_A(x_i))$  represents the height of a fuzzy set.

If at least one element of the fuzzy set has a membership grade of 1.0, the fuzzy set is called normalized. Figure 19.15.2 illustrates both a nonnormalized and a normalized fuzzy set.

The following properties of fuzzy sets, which are obvious extensions of the corresponding definitions for ordinary (crisp) sets, are defined herein according to Zaheh (1965) and Klir and Folger (1988).

FIGURE 19.15.1 (a) Discrete and (b) continuous fuzzy set.

FIGURE 19.15.2 (a) Nonnormalized and (b) normalized fuzzy set.

Two fuzzy sets  $A$  and  $B$  are equal,  $A = B$ , if and only if  $\mu_A(x) = \mu_B(x)$  for every element  $x$  in  $X$  (see [Figure 19.15.3](#)).

The complement of a fuzzy set  $A$  is a fuzzy set  $\bar{A}$  defined as

$$\mu_{\bar{A}}(x) = 1 - \mu_A(x) \tag{19.15.2}$$

[Figure 19.15.4](#) shows both discrete and continuous fuzzy sets and their complements.

FIGURE 19.15.3 Two equal fuzzy sets,  $A = B$ .

FIGURE 19.15.4 (a) Discrete fuzzy set A, (b) complement  $\bar{A}$  of fuzzy set A, (c) continuous fuzzy set B, and (d) complement  $\bar{B}$  of fuzzy set B.

If the membership grade of each element of the universal set X in fuzzy set B is less than or equal to its membership grade in fuzzy set A, then B is called a subset of A. This is denoted  $B \subseteq A$ . Figure 19.15.5 illustrates this situation.

The union of two fuzzy sets A and B with membership functions  $\mu_A(x)$  and  $\mu_B(x)$  is a fuzzy set  $C = A \cup B$  such that

$$\mu_C(x) = \max[\mu_A(x), \mu_B(x)] \tag{19.15.3}$$

**FIGURE 19.15.5** Fuzzy set A and its subset B.

for all  $x$  in  $X$ .

Conversely, the intersection of two fuzzy sets A and B with membership functions  $\mu_A(x)$  and  $\mu_B(x)$ , respectively, is a fuzzy set  $C = A \cap B$  such that

$$\mu_C(x) = \min[\mu_A(x), \mu_B(x)] \tag{19.15.4}$$

for all  $x$  in  $X$ .

Figure 19.15.6 illustrates two fuzzy sets A and B, the union set  $A \cup B$  and the intersection set  $A \cap B$ .

**FIGURE 19.15.6** (a) Two fuzzy sets, (b) union of fuzzy sets  $A \cup B$ , and (c) intersection of fuzzy sets  $A \cap B$ .

An empty fuzzy set  $A$  is a fuzzy set with a membership function  $\mu_A(x) = 0$  for all elements  $x$  in  $X$  (see Figure 19.15.7).

FIGURE 19.15.7 Empty fuzzy set.

Two fuzzy sets  $A$  and  $B$  with respective membership function  $\mu_A(x)$  and  $\mu_B(x)$  are disjoint if their intersection is empty (see Figure 19.15.8).

FIGURE 19.15.8 Disjoint fuzzy sets.

An  $\alpha$ -cut of a fuzzy set  $A$  is an ordinary (crisp) set  $A_\alpha$  containing all elements that have a membership grade in  $A$  greater or equal to  $\alpha$ . Therefore,

$$A_\alpha = \{x | \mu_A(x) \geq \alpha\} \tag{19.15.5}$$

From Figure 19.15.9, it is clear that  $\alpha = 0.5$ , the  $\alpha$ -cut of the fuzzy set  $A$  is the crisp set  $A_{0.5} = \{x_5, x_6, x_7, x_8\}$  and for  $\alpha = 0.8$ , the  $\alpha$ -cut of the fuzzy set  $A$  is the crisp set  $A_{0.8} = \{x_7, x_8\}$ .

A fuzzy set is convex if and only if all of its  $\alpha$ -cuts are convex for all  $\alpha$  in the interval  $[0,1]$ . Figure 19.15.10 shows both a convex and a nonconvex fuzzy set.

A fuzzy number  $\tilde{N}$  is a normalized and convex fuzzy set of the real line whose membership function is piecewise continuous and for which it exists exactly one element with  $\mu_{\tilde{N}}(x_0) = 1$ . As an example, the real numbers close to 50 are shown by four membership functions in Figure 19.15.11.

The scalar cardinality of a fuzzy set  $A$  is the summation of membership grades of all elements of  $X$  in  $A$ . Therefore,

$$|A| = \sum_x \mu_A(x) \tag{19.15.6}$$

FIGURE 19.15.9  $\alpha$ -cut of a fuzzy set.

FIGURE 19.15.10 Convex and non-convex fuzzy set.

FIGURE 19.15.11 Membership functions of fuzzy sets of real numbers close to 50.

For example, the scalar cardinality of the fuzzy set A in Figure 19.15.4(a) is 2.5. Obviously, an empty fuzzy set has a scalar cardinality equal to zero. Also, the scalar cardinality of the fuzzy complement set is equal to scalar cardinality of the original set. Therefore,

$$|A| = |\bar{A}| \tag{19.15.7}$$

One of the basic concepts of fuzzy set theory is the extension principle. According to this principle (Dubois and Prade, 1980), given (a) a function  $f$  mapping points in the ordinary set  $X$  to points in the ordinary set  $Y$ , and (b) any fuzzy set  $A$  defined on  $X$ ,

$$A = \{\mu_A(x_1)|x_1, \mu_A(x_2)|x_2, \dots, \mu_A(x_n)|x_n\}$$

then the fuzzy set  $B = f(A)$  is given as

$$B = f(A) = \{\mu_A(x_1)|f(x_1), \mu_A(x_2)|f(x_2), \dots, \mu_A(x_n)|f(x_n)\} \tag{19.15.8}$$

If more than one element of the ordinary set  $X$  is mapped by  $f$  to the same element  $y$  in  $Y$ , then the maximum of the membership grades in the fuzzy set  $A$  is considered as the membership grade of  $y$  in  $f(A)$ .

As an example, consider the fuzzy set in Figure 19.15.4(a), where  $x_1 = -2$ ,  $x_2 = 2$ ,  $x_3 = 3$ ,  $x_4 = 4$ , and  $x_5 = 5$ . Therefore,  $A = \{0.8|-2, 0.6|2, 0.2|3, 0.4|4, 0.5|5\}$  and  $f(x) = x^4$ . By using the extension principle, we obtain

$$\begin{aligned} f(A) &= \{\max(0.8, 0.6)|2^4, 0.2|3^4, 0.4|4^4, 0.5|5^4\} \\ &= \{0.8|16, 0.2|81, 0.4|256, 0.5|625\} \end{aligned}$$

As shown by Klir and Folger (1988), degrees of association can be represented by membership grades in a fuzzy relation. Such a relation can be considered a general case for a crisp relation.

Let  $P$  be a binary fuzzy relation between the two crisp sets  $X = \{4, 8, 11\}$  and  $Y = \{4, 7\}$  that represents the relational concept “very close.” This relation can be expressed as:

$$P(X, Y) = \{1|(4, 4), 0.7|(4, 7), 0.6|(8, 4), 0.9|(8, 7), 0.3|(11, 4), 0.6|(11, 7)\}$$

or it can be represented by the two dimensional membership matrix

	$y_1$	$y_2$
$x_1$	1.0	0.7
$x_2$	0.6	0.9
$x_3$	0.3	0.6

Fuzzy relations, especially binary relations, are important for many engineering applications.

The concepts of domain, range, and the inverse of a binary fuzzy relation are clearly defined in Zadeh (1971), and Klir and Folger (1988).

The max-min composition operation for fuzzy relations is as follows (Zadeh, 1991; Klir and Folger, 1988):

$$\mu_{P \circ Q}(x, z) = \max_{y \in Y} \min[\mu_P(x, y), \mu_Q(y, z)] \tag{19.15.9}$$

for all  $x$  in  $X$ ,  $y$  in  $Y$ , and  $z$  in  $Z$ , where the composition of the two binary relations  $P(X, Y)$  and  $Q(Y, Z)$  is defined as follows:

$$R(X, Z) = P(X, Y) \circ Q(Y, Z) \tag{19.15.10}$$

As an example, consider the two binary relations

$$P(X, Y) = \{1.0|(4, 4), 0.7|(4, 7), 0.6|(8, 4), 0.9|(8, 7), 0.3|(11, 4), 0.6|(11, 7)\}$$

$$Q(Y,Z) = \{0.8|(4,6), 0.5|(4,9), 0.2|(4,12), 0.0|(4,15), 0.9|(7,6), 0.8|(7,9), 0.5|(7,12), 0.2|(7,15)\}$$

The following matrix equations illustrate the max-min composition for these binary relations

$$\begin{bmatrix} 1.0 & 0.7 \\ 0.6 & 0.9 \\ 0.3 & 0.6 \end{bmatrix} \circ \begin{bmatrix} 0.8 & 0.5 & 0.2 & 0.0 \\ 0.9 & 0.8 & 0.5 & 0.2 \end{bmatrix} = \begin{bmatrix} 0.8 & 0.7 & 0.5 & 0.2 \\ 0.9 & 0.8 & 0.5 & 0.2 \\ 0.6 & 0.6 & 0.5 & 0.2 \end{bmatrix}$$

Zadeh (1971) and Klir and Folger (1988), define also an alternative form of operation on fuzzy relations, called max-product composition. It is denoted as  $P(X,Y) \otimes Q(Y,Z)$  and is defined by

$$\mu_{P \otimes Q}(x,z) = \max_{y \in Y} [\mu_P(x,y), \mu_Q(y,z)] \tag{19.15.11}$$

for all  $x$  in  $X$ ,  $y$  in  $Y$ , and  $z$  in  $Z$ . The matrix equation

$$\begin{bmatrix} 1.0 & 0.7 \\ 0.6 & 0.9 \\ 0.3 & 0.6 \end{bmatrix} \times \begin{bmatrix} 0.8 & 0.5 & 0.2 & 0.0 \\ 0.9 & 0.8 & 0.5 & 0.2 \end{bmatrix} = \begin{bmatrix} 0.8 & 0.7 & 0.5 & 0.2 \\ 0.9 & 0.8 & 0.5 & 0.2 \\ 0.6 & 0.6 & 0.5 & 0.2 \end{bmatrix}$$

illustrates the max product composition for the pair of binary relations  $P(X,Y)$  and  $Q(Y,Z)$  previously considered.

A crisp binary relation among the elements of a single set can be denoted by  $R(X,X)$ . If this relation is reflexive, symmetric, and transitive, it is called an equivalence relation (Klir and Folger, 1988).

A fuzzy binary relation  $S$  that is reflexive

$$\mu_S(x,x) = 1 \tag{19.15.12}$$

symmetric

$$\mu_S(x,y) = \mu_S(y,x) \tag{19.15.13}$$

and transitive

$$\mu_S(x,z) = \max_y \min [\mu_S(x,y), \mu_S(y,z)] \tag{19.15.14}$$

is called a similarity relation (Zadeh, 1971). Equations (19.15.12), (19.15.13), and (19.15.14) are valid for all  $x,y,z$  in the domain of  $S$ . A similarity relation is a generalization of the notion of equivalence relation.

Fuzzy orderings play a very important role in decision-making in a fuzzy environment. Zadeh (1971) defines fuzzy ordering as a fuzzy relation which is transitive. Fuzzy partial ordering, fuzzy linear ordering, fuzzy preordering, and fuzzy weak ordering are also mathematically defined by Zadeh (1971) and Zimmermann (1991).

The notion of fuzzy relation equation, proposed by Sanchez (1976), is an important notion with various applications. In the context of the max-min composition of two binary relations  $P(X,Y)$  and  $Q(Y,Z)$ , the fuzzy relation equation is as follows

$$P \circ Q = R \tag{19.15.15}$$

where **P** and **Q** are matrices of membership functions  $\mu_p(x,y)$  and  $\mu_q(y,z)$ , respectively, and **R** is a matrix whose elements are determined from Equation (19.15.9). The solution in this case is unique. However, when **R** and one of the matrices **P**, **Q** are given, the solution is neither guaranteed to exist nor to be unique (Klir and Folger, 1988).

Another important notion is the notion of fuzzy measure. It was introduced by Sugeno (1977). A fuzzy measure is defined by a function which assigns to each crisp subset of *X* a number in the unit interval [0,1]. This number represents the ambiguity associated with our belief that the crisp subset of *X* belongs to the subset *A*. For instance, suppose we are trying to diagnose a mechanical system with a failed component. In other terms, we are trying to assess whether this system belongs to the set of systems with, say, safety problems with regard to failure, serviceability problems with respect to deflections, and serviceability problems with respect to vibrations. Therefore, we might assign a low value, say 0.2 to failure problems, 0.3 to deflection problems, and 0.8 to vibration problems. The collection of these values constitutes a fuzzy measure of the state of the system.

Other measures including plausibility, belief, probability, and possibility measures are also used for defining the ambiguity associated with several crisp defined alternatives. For an excellent treatment of these measures and of the relationship among classes of fuzzy measures see Klir and Folger (1988).

Measures of fuzziness are used to indicate the degree of fuzziness of a fuzzy set (Zimmermann, 1991). One of the most used measures of fuzziness is the entropy. This measure is defined (Zimmermann, 1991) as

$$d(A) = h \sum_{i=1}^n S(\mu_A(x_i)) \tag{19.15.16}$$

where *h* is a positive constant and *S*( $\alpha$ ) is the Shannon function defined as

$S(\alpha) = -\alpha \ln \alpha - (1 - \alpha) \ln(1 - \alpha)$  for rational  $\alpha$ . For the fuzzy set in Figure 19.15.4(a), defined as

$$A = \{0.8| - 2, 0.6|2, 0.2|3, 0.4|4, 0.5|5\}$$

the entropy is

$$\begin{aligned} d(A) &= h(0.5004 + 0.6730 + 0.5004 + 0.6730 + 0.6931) \\ &= 3.0399 h \end{aligned}$$

Therefore, for *h* = 1, the entropy of the fuzzy set *A* is 3.0399.

The notion of linguistic variable, introduced by Zadeh (1973), is a fundamental notion in the development of fuzzy logic and approximate reasoning. According to Zadeh (1973), linguistic variables are “variables whose values are not members but words or sentences in a natural or artificial language. The motivation for the use of words or sentences rather than numbers is that linguistic characterizations are, in general, less specific than numerical ones.” The main differences between fuzzy logic and classical two-valued (e.g., true or false) or multivalued (e.g., true, false, and indeterminate) logic are that (a) fuzzy logic can deal with fuzzy quantities (e.g., most, few, quite a few, many, almost all) which are in general represented by fuzzy numbers (see Figure 19.15.11), fuzzy predicates (e.g., expensive, rare), and fuzzy modifiers (e.g., extremely, unlikely), and (b) the notions of truth and false are both allowed to be fuzzy using fuzzy true/false values (e.g., very true, mostly false). As Klir and Folger (1988) stated, the ultimate goal of fuzzy logic is to provide foundations for approximate reasoning. For a general background on fuzzy logic and approximate reasoning and their applications to expert systems, the reader is referred to Zadeh (1973, 1987), Kaufmann (1975), Negoita (1985), and Zimmermann (1991), among others.

Decision making in a fuzzy environment is an area of continuous growth in engineering and other fields such as economics and medicine. Bellman and Zadeh (1970) define this process as a “decision

process in which the goals and/or the constraints, but not necessarily the system under control, are fuzzy in nature.”

According to Bellman and Zadeh (1970), a fuzzy goal  $G$  associated with a given set of alternatives  $X = \{x\}$  is identified with a given fuzzy set  $G$  in  $X$ . For example, the goal associated with the statement “ $x$  should be in the vicinity of 50” might be represented by a fuzzy set whose membership function is equal to one of the four membership functions shown in [Figure 19.15.11](#). Similarly, a fuzzy constraint  $C$  in  $X$  is also a fuzzy set in  $X$ , such as “ $x$  should be substantially larger than 20.”

Bellman and Zadeh (1970) define a fuzzy decision  $D$  as the confluence of goals and constraints, assuming, of course, that the goals and constraints conflict with one another. Situations in which the goals and constraints are fuzzy sets in different spaces, multistage decision processes, stochastic systems with implicitly defined termination time, and their associated optimal policies are also studied in Bellman and Zadeh (1970).

## Further Information

The more than 5000 publications that exist in the field of fuzzy sets are widely scattered in many books, journals, and conference proceedings. For newcomers, good introductions to the theory and applications of fuzzy sets are presented in (a) *Introduction to the Theory of Fuzzy Sets*, Volume I, Academic Press, New York, 1975, by Arnold Kaufmann; (b) *Fuzzy Sets and Systems: Theory and Applications*, Academic Press, New York, 1980, by Didier Dubois and Henri Prade; (c) *Fuzzy Sets, Uncertainty and Information*, Prentice Hall, Englewood Cliffs, NJ, 1988, by George Klir and Tina Folger, and (d) *Fuzzy Set Theory and Its Applications*, 2nd ed., Kluwer Academic Publishers, Boston, 1991, by H.-J. Zimmerman, among others.

The eighteen selected papers by Lotfi A. Zadeh grouped in *Fuzzy Sets and Applications*, John Wiley & Sons, New York, 1987, edited by R. Yager, S. Ovchinnikov, R.M. Tong, and H.T. Nguyen are particularly helpful for understanding the developments of issues in fuzzy set and possibility theory. Also, the interview with Professor Zadeh published in this book illustrates the basic philosophy of the founder of fuzzy set theory.

## 20.1 Patents and Other Intellectual Property

*Thomas H. Young\**

The purpose of this chapter is to provide some very general information about intellectual property protection (especially patents) to nonlawyers.\*\* It is also intended to provide some suggestions for “self-help” to engineers that will enable them to improve the possibility of obtaining and securing appropriate protection for their ideas and developments even before they consult a lawyer. One of the questions an intellectual property attorney frequently hears is: “I have a great idea. How do I protect it?” This section should provide at least a starting point for answering that question.

In the case of patents, this section is designed to assist engineers and/or inventors in understanding what is expected of them and how to assist their patent lawyers or agents in the process of protecting their inventions. Be forewarned, however; the process of obtaining patent, trade secret, and/or copyright protection on such a development is not necessarily a linear one and is often neither short nor easy.

### Patents\*\*\*

*What is a patent?* The authorization for a patent system stems from the United States Constitution, which provides:

The Congress shall have power... to promote the progress of science and useful arts, by securing for limited times to authors and inventors the exclusive right to their respective writings and discoveries.  
U.S. Const. Art. I, § 8.

Although the concept of a patent system did not originate in the United States, the drafters of the Constitution thought patents and copyrights significant enough to provide for them in the fundamental predicates on which our government is founded. Indeed, Thomas Jefferson, as Secretary of State, was one of the first patent “examiners.”

The premise of the Constitutional provision is to encourage the disclosure of inventions in the interest of promoting future innovation. Specifically, if inventors were not provided with patent protection for their innovations, they would seek to exploit them in secret. Thus, no one else would be able to benefit from and expand on their inventions, so technology would not move as rapidly as it would with full disclosure. Following enactment of the Constitution, Congress promptly adopted and has continuously maintained and updated laws implementing a patent system.

---

\* Mr. Young has practiced intellectual property law for more than 20 years, is a partner in the Denver office of the international law firm of Dorsey & Whitney, and has been an adjunct professor of patent and trademark law at the University of Colorado law school. The author acknowledges with great appreciation the assistance of Mr. Gregory D. Leibold, an attorney focusing on intellectual property law at Dorsey & Whitney in the preparation of this article.

\*\* This section is in no way intended to provide the reader with all of the information he or she may need to evaluate or obtain intellectual property protection in particular situations on their own. Additional information is available from the Patent and Trademark Office and the Copyright Office in Washington, D.C. and other published references on these subjects. For information on patents and trademarks, the reader may contact the Commissioner of Patents and Trademarks, Washington, D.C. 20231, (703)308-3457. For information regarding copyrights, contact the Register of Copyrights, Library of Congress, Washington, D.C. 20559, (202)707-3000. When applying the legal requirements to a specific issue, the reader is encouraged to consult with a knowledgeable lawyer.

\*\*\* The patent laws are codified in 35 United States Code (i.e., “U.S.C.”) § 100 *et seq.* Regulations implementing these patent laws, particularly as they relate to the operation of the Patent Office, are found in volume 37 of the Code of Federal Regulations (i.e., “C.F.R.”). The internal rules of the Patent Office relating to the examination of patents are contained in the Patent Office “Manual of Patent Examining Procedure” or “M.P.E.P.” For more information on patents, the following treatises may be helpful: *Patents*, Donald S. Chisum, Matthew Bender & Co., New York, 1995; *Patent Law Fundamentals*, Peter D. Rosenberg, 2nd ed., Clark Boardman Callaghan, Rochester, NY, 1995.

Strictly speaking, patents are not contracts; however, because of the premise behind the Constitutional provision, patents have sometimes been analogized to contracts between inventors and the U.S. Government. The Government agrees to allow the inventor exclusive rights to his or her invention for a period of time. In exchange, the inventor agrees to disclose his or her invention, thereby allowing other inventors the benefit of the patentee's work and enabling others to practice the invention after the patent has expired.

*What rights does a patent confer?* After a patent issues, the patentee has the right to exclude others from making, using, or selling the subject matter claimed in the patent. Currently, the term of a U.S. patent is 20 years from the date the patent was filed. The patentee is not required to license others to use the invention.

Nevertheless, a patent does not confer the right to do anything. In fact, it is frequently the case that an inventor will receive a patent but will be unable to use the patented invention because it infringes on another's patent. For example, if A obtained the first patent on a laser and B later obtains a patent on the use of a laser in surgery, B cannot make or use the laser in surgery, because it would infringe A's patent. By the same token, however, A cannot use this laser in surgery, because it would infringe B's patent. In addition, patent rights are territorially limited, and the use of the same invention in different countries may have different ramifications. Finally, regardless of patent rights, the use of certain technologies (e.g., pharmaceuticals) may be limited by other government regulations and practical considerations.

A significant advantage of a patent over other forms of intellectual property protection, such as copyright or trade secret, is that a patent can be enforced against anyone who utilizes the claimed technology regardless of whether that person copied or misappropriated the technology. Independent development of an infringing device is not a defense.

*Who can obtain a patent?* Anyone who is the first to invent something that falls into a category of subject matter that is deemed to be patentable may obtain a U.S. patent. A single patent can have several inventors if the subject matter of one or more claims in the patent was jointly conceived or reduced to practice. In that case, each inventor, in essence, obtains his or her own rights to the patent, subject to an obligation to account to the other inventor(s) for their respective share of the remuneration. The patent must be obtained by the true inventors or it may be invalid. Thus, persons who did not contribute to an invention should not be named as inventors regardless of the desirability of recognizing their moral or economic support to the process of inventing.

*What subject matter is patentable?* U.S. patent law provides that:

Whoever invents or discovers any new and useful *process, machine, manufacture, or composition of matter*, or any new and useful *improvement* thereof, may obtain a patent therefor, subject to the conditions of patentability and requirements of this title. [emphasis added.] 35 U.S.C. § 101.

Although the categories of patentable items seem archaic, Congress acknowledged that it intended this language to "include anything under the sun that is made by man."

The development of significant new technologies, such as computers and biotechnology, have challenged the limits of proper patentable subject matter. Nevertheless, with some diversions along the way, courts have continued to expand those boundaries so that they now include computer software and engineered life forms when embodied in properly drafted patent claims. In general, however, laws of nature, scientific truths, and mathematical algorithms are not patentable subject matter in and of themselves. New and useful applications of those concepts, however, may be patented.

*What are the standards for patentability?* In order to merit a patent, an invention must be new, useful, and nonobvious. The "new" and "useful" standards are defined precisely as one might expect. One may not obtain a patent on an invention that has been invented before and, therefore, is not novel or on one that has no practical utility.

The "nonobvious" standard is a more difficult one. Even if an invention has not been created before, in order to be patentable, it must not have been obvious to one of ordinary skill in the technical field of the invention at the time the invention was made. In other words, a valid patent cannot be obtained on

an invention that merely embodies a routine design or the application of principles within the ordinary skill of the art. Whether an invention meets the standard for nonobviousness involves a factual inquiry into the state of the art, the level of ordinary skill in the art, and the differences between what was known in the art and the invention at the time it was made. In addition, both the Patent Office and courts will look at objective evidence of nonobviousness, including the context in which the invention was made (e.g., whether or not there was a long-standing problem that had not been solved by others), recognition of the invention, and its success in the marketplace. Nevertheless, the determination of nonobviousness is not precise. Indeed, the “beauty” of many of the most significant inventions is embodied in their simplicity. As such, they are temptingly “obvious” after the fact, even though courts are theoretically constrained from utilizing hindsight in determining nonobviousness.

*How is a U.S. patent obtained?* The process of obtaining a patent starts with the invention. Invention, under U.S. patent law, has two parts. First, there is the “conception” of the invention, which literally refers to the date when the inventor first thought of the novel aspect of his or her invention. Second, there is the “reduction to practice” of the invention, which can refer to a variety of activities. In the case of a mechanical invention, for example, reduction to practice occurs when a working version of the machine is built embodying the invention. However, there is also a legal concept called “constructive” reduction to practice, which occurs when the inventor files a patent application with the Patent Office.

The date of invention is very important in the United States. Unlike every other country in the world, the United States awards patents to the first person to invent it, rather than the first person to file a patent application. Importantly, the date of conception serves as the date of invention in the United States so long as the inventor was “diligent” in reducing the invention to practice. If the inventor is not continuously “diligent” (and there is some question as to what that word means, exactly), then the date of invention is considered the date on which the inventor was continuously diligent until the invention was reduced to practice.

The date of invention can be critical to obtaining a patent in the United States. In foreign countries, however, the only date that matters is the date on which the inventor first filed the patent application. Filing a patent application in the United States will normally preserve the inventor’s rights abroad if the appropriate foreign patent applications are filed within 1 year of the U.S. filing date and the other requirements of the Patent Cooperation Treaty are met. Ideally, an inventor should file a patent application directly after the conception of the invention in order to achieve the earliest effective date in both the United States and abroad.

Before filing a patent application, an inventor should have a “prior art search” performed. *Prior art* is a term used to refer, in part, to any printed materials published before the inventor files the application that are relevant to the issues of novelty and nonobviousness. Having a search done for prior art is a good way to ensure that the invention for which the application is written is patentable and may also provide some insight into whether or not practice of the invention would infringe the rights of others. The prior art search enables a preliminary determination of the patentability of the invention and, if it appears patentable, the identification of the patentable features to be focused upon in drafting the application. Nevertheless, there is always some prior art that will not be accessible using economically viable means at the time of application, so an inventor can never be completely sure about the novelty of his/her invention at the time of filing.

An inventor can apply for a patent from the Patent Office either *pro se* (i.e., on his own) or through a registered patent agent or attorney. The process of obtaining a patent is a complex one, and the inventor’s chances of obtaining a valid patent of the broadest possible scope are greatly increased by the use of a qualified agent or attorney. Lists of registered patent attorneys and agents are available from the Patent Office. Patent attorneys may also be located through the *Martindale-Hubbell Law Directory*, state and local bar associations, and other publications, directories, and professional organizations.

This is not to say that inventors, themselves, have not successfully obtained patents from the Patent Office. Nevertheless, busy patent examiners are easily frustrated by *pro se* applicants’ lack of familiarity with patent application requirements and Patent Office rules, and those frustrations are evidenced, consciously or unconsciously, in Patent Office “rejections.” Familiarity with the stated requirements of

the Patent Office and knowledge of its informal workings greatly increase the chances of successfully obtaining a valid patent with the broadest possible scope.

A patent application contains a number of parts, all of which generally fall into two main categories. The first group, known as the “specification,” contains a detailed written description of the invention including relevant drawings or graphs and any examples. The purpose of the specification is to “enable” one of ordinary skill in the art to make and use the invention. In addition, the applicant must disclose the “best mode” of practicing the invention. The “enablement” and “best mode” requirements are intended to fulfill the constitutional purpose of full disclosure of the invention. Thus, a patent that was otherwise properly granted by the Patent Office may nevertheless be invalidated if it is later determined that the inventor failed to teach others how to utilize the invention or tried to maintain the best mode of practicing the invention as a secret.

The second major part of the patent application is the “claims,” which are the separately numbered paragraphs appearing at the end of a patent. The claims define the scope of protection that the patent will confer, and they must be clear, definite, and unambiguous. The goal of the applicant in prosecuting a patent is to obtain claims that cover the invention as broadly as possible without including subject matter that is obvious or not novel. For example, if A invented the two-wheeled bicycle, he might claim a vehicle utilizing two round rotating objects for conveyance. Such a claim might prove to be invalid, for example, if carts were previously known. In such a situation, it would be better to claim the bicycle more narrowly as a vehicle with two wheels in tandem.

Once the application is drafted and submitted to the Patent Office, the Patent Office classifies the invention and sends it to an appropriate “art unit.” The Patent Office is divided into separate art units that employ examiners who are knowledgeable about, or at least familiar with, particular fields of technology. Eventually, an examiner will read the application, focusing mainly on the claims since they define the legal parameters of the invention. After performing his own patentability search and reviewing the application for other technical defects, the examiner may either “allow” the application to become a patent or reject the application on the grounds that it lacks substantive merit and/or fails to comply with the formalities of a proper patent application. If the examiner rejects some of the claims, he will explain why the claims are not patentable in light of the specific prior art references. This will start a series of communications (in writing, by telephone, or in person) between the examiner and the applicant (or the registered attorney of record). During that process, the claims of the patent will be amended as becomes necessary in an attempt to define patentable subject matter.

If the application is eventually allowed, then the patent will be valid from the date of issuance until 20 years after the date the application was originally filed. If the application is not allowed by the examiner and is finally rejected, the inventor can (1) abandon the application and the effort to obtain a patent, (2) file a “continuation” application and start the process over, or (3) appeal the rejection to the Board of Patent Appeals and Interferences and eventually to other courts. It is not uncommon for the process from filing of the application until allowance to take several years.

After the application is submitted, it is appropriate to advise the public that a patent is “pending.” This remains true until the application has been abandoned or has issued as a patent. Generally, neither the contents of the application nor even the fact that an application has been filed are publicly available from the Patent Office absent the consent of the applicant. After the patent issues, the patent number should be marked on products embodying the patent. This notice serves to start the period running for the collection of damages for patent infringement. Absent such notice, damages do not begin to run until the infringer receives actual notice of the patent.

Several aspects of this process bear particular note. First, once an application has been filed, the Patent Office does not permit the introduction of “new matter” into the application. Although typographical and other simple errors in the application may be corrected, an applicant may not insert additional written material or drawings (e.g., an additional embodiment or further improvement). The reason for this is simple — because the date of invention and the date of filing are both important for U.S. and foreign priority purposes, the Patent Office could not operate efficiently if the subject matter of the application were constantly amended. There would be numerous continuing disputes as to the effective date to be

afforded the subject matter of an amended application. Instead, if it is necessary to amend the application substantively, a new “continuation-in-part” application must be filed. If it is filed while the original or “parent” application is still pending, the subject matter common to both applications will retain the original filing date, while the new material will only be afforded the filing date of the later continuation-in-part application. The prohibition on adding “new matter,” therefore, places a premium on filing an original application that completely and accurately describes the invention.

Second, the patent application process frequently is not linear. Seldom does an invention constitute a static concept or a single finished embodiment. The concept may change as its full ramifications are slowly revealed through practical experience, and its embodiment in physical articles, compositions, or processes may change after the patent application is filed. Thus, as the invention evolves, it may be necessary to file further continuation-in-part applications to cover the developments which appear during this evolutionary process. To achieve the ultimate objective of obtaining patent protection on commercially viable aspects of the invention, it may be necessary for the inventor and legal counsel to reevaluate the merits of the original application and to take appropriate corrective action in the patent prosecution process.

*How can the inventor help?* There are a variety of ways in which the inventor can and, in fact, should aid in the process of obtaining a patent.

First, and perhaps foremost, an inventor should keep detailed notes on his research and development throughout the inventive process. All research and/or discoveries should be documented, dated, and witnessed by a noninventor because they may become important later for purposes of determining who was the first to invent. The date of invention may also be useful in convincing the Patent Office or a court that certain prior art dated before the filing of the patent application should, nevertheless, not be applied. In preparing this documentation, it is important to realize that the testimony of the inventor himself or documents authenticated only by the inventor are generally not sufficient to prove priority. There are many reasons for this. Suffice it to say that there is a premium on having the records witnessed contemporaneously by at least one noninventor. Getting a noninventor to witness pages of a lab notebook is one way to accomplish this. Alternatively, the Patent Office will, for a nominal fee, accept and provide validation of “disclosure” documents evidencing the date of conception. This is probably the most unquestionable evidence of a date of conception.

An inventor can also assist by performing an informal prior art search of his own before contacting a patent attorney. Filing a patent application is expensive. An inventor should be as confident as possible that he has created something novel before spending the money to draft an application. Typically, a patent attorney will urge that a formal search be performed to ensure that the prior art that the Patent Office examiner is likely to access has been considered. Due to the proliferation of electronic databases for scientific and industry literature, however, there may be additional prior art which is more readily accessible to the inventor. A search of this material can be very helpful to the patent attorney in isolating the patentable features of the invention and improving the chances of obtaining a valid patent.

All prior art located by or known to the inventor should be disclosed to the patent attorney so that it can be evaluated and disclosed to the Patent Office, if necessary. In that regard, both an applicant and his attorney are under an affirmative duty to disclose relevant prior art to the Patent Office, and failure to do so can lead to invalidation of the patent.

Once a prior art search has been performed, an inventor should file an application as early as practically possible. As noted previously, this will protect the inventor’s rights in foreign countries as well as provide constructive reduction to practice of the invention if it has not already been embodied in a working prototype. Nevertheless, some delay in filing may be desirable in order to permit further testing and corroboration. This is permissible, and in many instances desirable, bearing in mind that under U.S. patent law an application *must* be filed within 1 year of the first public use, disclosure, sale, or offer of sale of the invention. This deadline cannot be extended and, if violated, will automatically result in the invalidation of the patent. Many other countries do not have a 1 year “grace” period; a patent application is immediately barred once there has been a public disclosure in that country or elsewhere. Although there is an “experimental use” exception in the United States, it is limited to technical experiments (as

opposed to test marketing) that are appropriately documented. To be safe, the inventor should contact a patent attorney before publicly disclosing or using an invention or offering it for sale. If any of those events have already occurred, they should be immediately called to the patent attorney's attention.

The inventor is also instrumental in drafting the patent application. The inventor must make sure that the specification is accurate, enables one skilled in the art to practice the invention, and discloses the best way to make and use the invention. Although the art of claim drafting is somewhat of an acquired skill, the inventor should also be very involved in that process to make sure that the claims cover the invention and are not easily designed around. Sometimes a patent attorney will draft claims that do not expressly state a physical element or process step, but utilize "means-plus-function" language. In that case, it is highly desirable to describe as many means as possible for fulfilling that element in the application itself, and the inventor is the best source of that type of information. In other words, the inventor should continuously be asking questions of his attorney about whether or not certain variations of his invention will be adequately protected by the claims as drafted. Finally, the inventor can and should be instrumental in helping the attorney identify the technical/practical differences between the invention and prior art. In short, the prosecution of a patent application should be a team effort between inventor and attorney at each step in the process.

## Trade Secrets\*

In some instances it may be desirable to protect new technology as a trade secret rather than by patent. For example, an invention may not be patentable; it may be one of numerous small items or "know how" that improve one's business. Such items are typically protected as trade secrets. While there is no formal method of acquiring trade secret protection as there is for patents and copyrights, attention must still be paid to their identification and protection. Also, unlike patents and copyrights, trade secrets are protected under state, rather than federal laws. Therefore, the nuances of trade secret protection may vary depending on which state's laws apply. There are, however, some general principles of trade secrets that are common to most jurisdictions.

*What is a trade secret?* A "trade secret" may include anything that gives a person an advantage over his competitors and is not generally known to them. It includes compilations of information such as customer lists, compositions, process techniques and parameters, and software. In determining whether or not something is a protectable trade secret, courts look at the following factors: (1) the extent to which the information is known outside of the trade secret owner's business; (2) the extent to which it is known by employees or others involved in the trade secret owner's business; (3) the extent of measures taken by the trade secret owner to guard the secrecy of the information; (4) the value of the information to the trade secret owner and to his competitors; (5) the amount of effort or money expended by the trade secret owner in developing the information; and (6) the ease or difficulty with which the information could be properly acquired or duplicated by others.

*What protection does a trade secret provide?* A trade secret protects the owner from improper appropriation of the secret through use or disclosure by a person having an obligation not to do so. The major advantage of a trade secret is that it may last indefinitely; the major defect is that if it is lost, it generally cannot be reclaimed. Unlike patent infringement, a person accused of stealing a trade secret can successfully defend such an accusation by showing that he independently developed the subject matter of the secret. Trade secret protection, therefore, is only as good as the inability of competitors to "reverse engineer" or independently develop it.

*How can one obtain a trade secret?* Whether or not one has a trade secret is ultimately determined judicially in an action for enforcement. The court will look at all of the factors previously noted. At that time it is usually too late to take the actions necessary to establish trade secret protection. Thus, there is a premium for the periodic review and implementation of a program for trade secret protection. Among

---

\* See, generally, the Uniform Trade Secrets Act § 1(4), 14 U.L.A. 537 (1980) and *Milgrim on Trade Secrets*, Roger M. Milgrim, Matthew Bender & Co., New York, 1995.

the steps that can be taken to protect trade secrets are (1) identifying the types of materials that are deemed to be trade secrets by an organization and notifying employees of the organization's policy to treat this information as trade secrets; (2) restricting access to the trade secrets to only those individuals who have a need to know and who are obligated by contract or otherwise not to use or disclose them; (3) taking physical precautions to limit access to trade secrets such as using locked file cabinets, vaults, etc. These are the most fundamental steps that can be taken.

Although legal counsel is frequently consulted in establishing a plan for protecting trade secrets, including the drafting of appropriate confidentiality agreements, the physical steps required should be put in place by the trade secret owner prior to legal consultation.

## Copyrights\*

Copyright protection is usually associated with writings, songs, paintings, sculpture, and other artistic endeavors. However, it also extends to certain technology, particularly software, databases, and certain architectural plans.

*What protection does a copyright provide?* Copyright protection is a matter of federal law. Under the federal Copyright Act, protection is available for "original" works of appropriate subject matter, such as those mentioned in the previous paragraph. A copyright provides the exclusive right to reproduce, publicly distribute, publicly perform, publicly display, and make derivative works from an original work of authorship. However, it protects only against "copying" of the protected work and does not provide protection where a work has been independently developed by another. Copying can be presumed where the third party had access to the copyrighted work and there is "substantial similarity" between the third party's work and the original. Further, in certain limited instances, a small portion of a work may be reproduced without liability as a "fair use." The parameters of the "fair use" doctrine are complicated, however, and they are beyond the subject of this section.

Only a modicum of creativity is needed to satisfy the requirement of "originality." On the other hand, protection is limited. It has frequently been stated that a copyright only protects the manner in which something is expressed, rather than the idea or content, which can be an extremely difficult distinction to make. For example, there is significant debate as to the appropriate scope of copyright protection, for both software and databases. Nevertheless, an advantage of a copyright is that it may last for a relatively long period of time. At a minimum, copyright in works created at this time last for the life of the author plus 50 years.

*How is a copyright obtained?* Theoretically, in order to obtain a copyright an author need only show that a work is original to him (i.e., that he is in fact the author). Federal protection for copyright attaches as soon as a writing is fixed in a tangible medium (i.e., as soon as it is put on paper, or in memory on a computer, or anywhere else that it can be "perceived"). Nevertheless, there are two important steps that should be taken to realize the full scope of that protection.

First, it is highly advisable to affix a copyright notice to the work. "Notice" is provided by affixing to the work: (1) the word "Copyright" or the "©" symbol, (2) the date of first publication, and (3) the name of the copyright owner. Notice should be affixed to the work in an obvious position (such as one of the first pages of a book, an entry screen of a computer program, etc.). A copyright notice should be placed on all drafts of material that may be subject to protection under copyright law. If an author fails to put the notice on his work, copyright protection is not lost; however, an infringer may then use the defense that he innocently thought that the work was within the public domain. Adequate notice precludes the "innocent" infringer defense, and, because it does not cost anything, notice is always a good idea.

In addition, registration of the copyright with the Register of Copyrights at the Library of Congress is also highly recommended. This procedure is relatively simple and inexpensive. It consists of filling

---

\* The federal laws on copyright are codified in the Lanham Act, § 1 *et seq.* For further information on copyrights, the following treatise may be helpful: *Nimmer on Copyright*, Melville B. & David Nimmer, Matthew Bender & Co., New York, 1995.

out a government form and submitting it with the appropriate filing fee and a sample of the work sought to be copyrighted. If the application is acceptable, the Copyright Office returns a copy of the application stamped with the copyright registration number.

In the case of software and databases, there has been concern that an unscrupulous competitor might attempt to purloin valuable information from the sample submitted with the application. In recognition of this problem, the Copyright Office has promulgated rules allowing the submission of only a limited portion of the software or database adequate to identify the copyrighted work.

Although federal registration is not necessary to perfect a copyright, it does have some significant advantages. First, it is necessary to obtain a registration in order to bring suit against an infringer. While it is possible to register the work on an expedited basis immediately prior to commencing the lawsuit, it is not advisable. Early registration (i.e., within 3 months of the first publication of the work) allows an author to elect to sue for “statutory” damages, which can be considerably easier to prove and, possibly, more munificent than “actual” damages. In addition, an author may be able to recover attorneys’ fees from a defendant in some cases, but only if the work in question was registered before or soon after publication. In sum, if an author believes that a work is important and might be copied, he should promptly register the work.

## Trademarks\*

Although trademark protection does not encompass technology per se, any summary of intellectual property protection would be incomplete without a few comments on the scope and availability of trademark rights.

*What is a trademark?* A trademark is anything that serves to identify the source of a product or service. Trademark protection can be obtained on a wide variety of items such as words, symbols, logos, slogans, shapes (if they are not functional), tones (such as NBC’s three-note tone), and even colors. A trademark owner may assert his rights against a third party that is engaged in conduct that is likely to cause consumers to believe that his goods or services emanate from, are associated or affiliated with, or are sponsored by the trademark owner.

The purpose of trademark protection is twofold: (1) to ensure the public that goods or services offered under a trademark have the quality associated with the trademark owner and (2) to preserve the valuable goodwill that the trademark owner has established by promoting the mark. Trademark rights may last indefinitely.

*How are trademark rights established?* Trademarks are protected under both federal and state law. There are two ways to obtain rights in a trademark: use or federal registration. Rights in a mark can be acquired simply by using the mark in connection with the goods and services. If the mark is a distinctive one (i.e., coined or “made-up” like “POLAROID”) rights are established immediately. On the other hand, if the mark is descriptive, the use must be so prominent and lengthy that the mark has acquired a “secondary meaning,” (i.e., the public has come to recognize the term as identifying the source of the goods and services rather than as a reference to the product or service itself). In either case, to establish rights through use, it is desirable to use the designation “™” in connection with the mark, thereby indicating that the owner of the mark asserts that it is a trademark under common law.

In contrast, the process of obtaining a federal trademark registration involves the filing of an application with the U.S. Patent and Trademark Office. The application identifies the mark, the goods and services with which it is used, and, if it is already in use, the date of first use and the date of first use in interstate commerce. A filing fee is also required but is relatively minimal. A trademark examiner will check the application substantively, including the review of previously issued trademarks, to see if there is any conflict. If the examiner allows the application, the mark is published in the *Official Gazette*, which is

---

\* The federal trademark laws are codified at 17 U.S.C. § 1 *et seq.* For further information on trademarks, the following treatise may be helpful: *McCarthy on Trademarks and Unfair Competition*, J. Thomas McCarthy, Clark Boardman Callaghan, Rochester, NY, 3rd ed., 1995.

a weekly publication of the Patent Office. If no one opposes the registration within 30 days after publication, then a registration will be issued. If there is an objection, then an opposition proceeding is initiated, and the applicant and the opposer essentially litigate to determine who should obtain the trademark registration. Provided that certain documents are subsequently filed with the Patent Office to affirm and renew the registration, the registration may last indefinitely. The existence of a federally registered trademark is designated by the symbol “®”, which is frequently seen on the shoulder of the mark.

A federal trademark registration is a powerful tool in protecting a trademark. By law it serves as “constructive” (i.e., assumed) notice of the registrant’s claim of rights throughout the United States. In essence, the registration acts like a recorded deed to real estate, and anyone who subsequently purchases that property without checking the recorded information does so subject to the interests of record. In contrast, the rights of one who attempts to acquire a trademark only through use are generally limited to the geographic area in which the mark is actually used. Others who subsequently use the mark in other areas of the country may also establish rights. Thus, the first step in selecting a trademark is to search the records of the Patent Office to determine whether or not a confusingly similar mark has previously been registered. Typically, a trademark search performed by a professional search organization will also reveal state registrations and other common law uses that might cause conflicts with the mark under consideration.

One other advantage to federal registration is that the registrant may begin to acquire protection on a mark prior to actual use. This is accomplished by filing an “intent-to-use” application on a mark that the applicant has made a *bona fide* decision to use. The application is examined as described previously. Although the mark must actually be placed in use before the registration is issued, the registration will be effective from the date of its filing. Thus, the public is on notice of the applicant’s potential rights as soon as the application is filed. The examination process will also give the applicant significant comfort that the mark is available for use before investing a great deal of money in its promotion.

## Final Observations

Selecting an appropriate method of acquiring intellectual property protection for a new development may involve several forms of protection. Software, for example, may be protected by patent, trade secret, and copyright protection and may be sold using a registered trademark. In addition, other legal means may be used to protect the software, including appropriate contractual provisions limiting and restricting the rights of a user acquired by license. Those contractual commitments may survive, even if the intellectual property protection is lost.

It is hoped that this section has provided at least a general overview by which the nonlawyer can begin to understand how to protect intellectual property. There are almost never any easy answers to the question of how to protect products, ideas, and services, and it is always advisable to consult a qualified attorney with specific questions. A knowledgeable client, however, can make a significant difference in achieving the strongest protection available.

## 20.2 Product Liability and Safety

---

George A. Peters

### Introduction

Almost all engineers, at some time in their career, can expect some direct contact or indirect involvement with the legal system. The contact may be in the form of having to answer written interrogatories on technical issues for a company defendant or plaintiff, being personally deposed and having to respond to oral questions under oath, appearing for a company during trial, assisting lawyers in a lawsuit, or personally being a defendant in a lawsuit. Most important is having the ability to translate legal requirements into engineering specifications to assure compliance with the law.

The old maxim “ignorance of the law is no excuse” should be supplemented by an understanding that ignorance of the law may result in unnecessary mistakes (illegal acts) and personal fear when first confronted by an unknown aspect of the legal process. It is essential that the engineer have sufficient understanding to avoid gross errors and omissions, to react appropriately to legal proceedings, and to want to build a basic foundation of knowledge that can be quickly enhanced when needed. This section is only a brief overview that might be illustrative and helpful in both understanding potential legal liability and how to avoid, prevent, or proactively minimize any such legal exposure. If product liability is legal fault for an unsafe design, the question then becomes how to achieve an appropriate level of safety.

### Legal Concepts

Fundamental to determining who might be legally “at fault” is the concept of *negligence* which is utilized worldwide in the apportionment of damages (legal redress). Negligence is the failure to exercise ordinary or reasonable care, which persons of ordinary prudence would use to avoid injury to themselves or others. The exact definition is given to jurors, usually in the form of approved jury instructions (the actual operative law), who then apply the law given to them to the facts and circumstances of the case before them. The defenses to allegations of negligence (absence of due care) are, usually, *contributory negligence* (fault) on the part of the plaintiff or *assumption of the risk* on the part of the plaintiff (that risk that is specific and voluntarily assumed, not general or coerced). If there is a violation of a statute or regulation there may be a rebuttable presumption of negligence. Compliance with a technical standard may be some evidence of the exercise of due care. Concepts of *strict liability* involve the presence of a defect that legally caused personal injury or property damage. There are many definitions of a *defect*, such as a failure to perform as safely as an ordinary consumer would expect when used in an intended or reasonably foreseeable manner or “excessive preventable risks.”

*Foreseeability* means that the personal injury, property damage, or environmental harm must have been predictable or knowable at the time of design, manufacture, or sale of the product. Generally, the law requires only *reasonable efforts* to prevent defects, deficiencies, or unsafe conditions. In other words, there should be efforts to predict possible harm and reasonably practical risk reduction efforts to minimize the harm.

The term *engineering malpractice* includes conduct that has personal legal consequences (professional liability) for the individual engineer, conduct that has adverse legal consequences for his or her employer (such as product liability or toxic torts), and conduct having moral or ethical consequences even though it may be legally protected (Peters, 1996a).

There are many other supplemental legal concepts and each state or jurisdiction has summaries of the law (Witkin, 1987–1990), approved jury instructions (Breckinridge, 1994), statutes enacted by the legislature, compendiums of case law decisions by the courts, and regulations issued by executive agencies (all of which are constantly being revised and expanded). Thus, the engineer should always consult with an attorney-at-law before making an interpretation or taking any action that might be within the province of a licensed professional.

There are thousands of technical standards issued by professional associations, trade groups, standards formulation organizations, and government agencies. Compliance with such standards is the first line of liability prevention, but such standards should be exceeded by a comfortable margin to accommodate design, material, fabrication, and in-use process variance (Council, 1989). However, there are other important liability prevention measures that should be undertaken during the design process and described in a product liability prevention plan.

## Risk Assessment

A central theme in liability prevention is “risk assessment”. The first step in such an assessment is to identify all probable *hazards* (those faults, failures, or conditions that could cause harm), then determine the quantitative *risk* for each (the frequency and severity of harm), and, finally, render a subjective judgment as to *danger* (the presence of excessive preventable danger). It is important to determine what kind of risk assessment is being made and to identify its objective as follows:

1. *Compliance*. The exact method of conducting a risk assessment may be specified by procurement specifications, industry standards, or government regulations. The design objective may be only compliance with the assessment requirement. However, in the process of performing a written risk assessment and classifying the risk into some severity level, it may result in a beneficial safety audit of the product. Where there is “residual risk,” the design of specific warnings and instructions may be required.
2. *Major Compliance Tasks*. Where safe performance is very important, a detailed engineering analysis may be required by contract or regulation. This might involve listing all probable hazards for each component, part, and subsystem, then attempting to quantify the risk estimate for each hazard at the  $10^{-6}$  level of attempted precision. Since this requires a major effort, the primary design and management objective should be product improvements and informed product assurance.
3. *Comparative Analysis*. Some risk assessments involve only an overall risk estimate which is then compared with other similar products or a wide range of products. The objective or use may be for marketing purposes or liability defense. Since the results are gross or macroscopic, such risk assessments generally do not result in product improvement.
4. *Risk Ratings*. Some trade associations may provide generic risk ratings for materials or products. The objective may be for an “informed choice” of procedures and field equipment in order to satisfy a legal “duty of care” or to help determine the “best practical means” of job performance.
5. *System Effectiveness*. Some risk assessments are performed early in the design process, perhaps as part of a reliability analysis, for the purpose of predicting final system effectiveness. The objective may be to check design efforts, reallocate available funds, or refocus management audits to achieve a desired level of system effectiveness. The process may be used to assure that desired system-of-systems performance is achievable.

From the societal viewpoint, some level of risk can be tolerable, acceptable, required, and specified. What is desired at a given locality or time period can be made known by the local common law, government regulations, trade standards, practices, customs, and expectations. From the engineering viewpoint, *risk levels are controllable, adjustable, manageable, and a consequence of the application of appropriate engineering techniques, skills, and information resources.*

## Engineering Analysis

Rather than rely only upon an engineer’s subjective and often biased judgment as to what constitutes a safe design, it is advisable to perform specific objective engineering analyses for design safety. This usually includes some systematic approach to identifying failure modes and field hazards, their risk consequences, and alternative design options that might improve the safety performance. This should

be supplemented by formal design review sessions that consider information from or about customers and learned intermediaries in the fabrication, packaging, shipping, distribution, and marketing system. Written hazard analyses should include consideration of legal duties (Peters, 1991a,b), liability prevention techniques (Peters, 1996b), and cultural attributes and technical information resources in the worldwide marketplace (Murakami, 1987, 1992). There should be a systems perspective, a cradle-to-ultimate-disposal philosophy, a true understanding of customer needs and characteristics, and appropriate application of specific design safety techniques.

Testing is required to *verify* the engineering analyses, to *prove* the inherent safety of the product or process system, and to *discover* all potential problems before they become manifest postsale. As part of a *product liability mitigation plan*, procedures and costs should be determined for possible accident investigations, product recalls, retrofits, and injury reparations. A continuing (postsale) *product surveillance plan* should cover all foreseeable users, servicing, maintenance, repair, modification, transport, disposal, and recycling of the product and its components. This permits early discovery and resolution of safety problems. It should also include a means for updating a knowledge bank of scientific, engineering, legal, insurance, patent, and foreign standards information useful for future design efforts as well as postsale obligations.

## Human Error

Human error is a major source of undesirable variance in human-machine interfaces. Unfortunately, many engineers neglect or virtually ignore the human factors aspects of product and system design. There should be some effort to control human performance and prevent human failure by designing for a wide range of human dimensions, characteristics, and predictable responses (Peters, 1996a). If possible, the physical attributes, kinetics, and creative perceptual abilities of human operators, maintenance and repair personnel, and bystanders should be utilized in design. Human factors should be part of any early engineering analysis, with appropriate testing and safeguarding for human error that cannot otherwise be eliminated. This includes mechanical guards, tamper-resistant features, safe-stop and limited movement switches, proximity sensors with directional control, built-in time for protective behavioral reactions, and the prevention of inadvertent activation and operation. One of the most important sources of helpful information on human error comes from incident and accident reconstruction, but the scope and bias of the inquiry may severely limit the design usefulness of the data obtained; for example,

1. The *fatalistic approach* where human error is considered as being inevitable in an imperfect world. If there is “no fault” other than by the person committing an error or omission, there is little incentive to investigate in detail to determine other factors for purposes of corrective action. This fosters the continuance of tolerable human error, persistent undesirable human error, and a lack of true recognition of causation and preventive actions.
2. The *behavioral approach* which has a focus on individual behavior in an attempt to develop “safer people,” safer attitudes, and to develop motivation to “act responsibly.” This may result in closer supervision and additional training, with some short-term benefits, but it does not permanently alter the error-inducing situation.
3. The *situational approach* to human error is to blame the situation, the work environment, group interactions, sociotechnical factors, and the overall circumstances of the situation. There is some benefit from a broader perspective to human error since it provides a better understanding of causation.
4. The *product design approach* has an emphasis on the interaction between the user and the engineered product to provide information useful to the design engineer.
5. The *multifactorial approach* is based on the assumption that there is multiple causation for each injury, damage, loss, harm, or error. If special attention is given to each substantial factor or cause, valuable design-oriented information can result. This multifaceted perspective of accident reconstruction has the greatest benefit and is compatible with concepts of pure comparative negligence and the allocation of damages in proportion to the degree of fault.

During any accident investigation or accident reconstruction, care should be exercised to prevent any “spoliation” or distraction of evidence. This requires trained specialists, since even slight changes to the product may obliterate information that becomes critical in later product evaluations.

## Warnings and Instructions

As a last resort, for residual risk, appropriate use of warnings and instructions is essential for product liability prevention and the safe use of products (Peters, 1993). Such communications require a specific design engineering effort, plus relevant testing, if they are to be effective. They include warning devices, warnings on labels and packaging, material safety data sheets, instructions for training, insertions in owner's or operator's manuals, and postsale advertisements and letters to all owners. Some regulations require that they be in two languages and in nonlanguage pictorials. Such hazard communications and procedural directions should not be the result of a cursory afterthought, but an ongoing integral part of the design process. There may be neuropsychological considerations in the presentation of information by visual or auditory displays, machine condition and status indicators, and computer-generated information that requires specialized knowledge and testing. The basic premise is to design a referent about a specific hazard so the target individual is adequately informed as to risk and has a reasonable choice as to avoidance behavior. Warnings that fail to communicate their intended message are functionally useless. There is considerable scientific and engineering information regarding the design of warnings and instructions, and the failure to heed such information may result in legal allegations about a failure to warn, instruct, test, or appropriately market a product. The issue becomes what proof exists about whether or not warnings, instructions, or representations would have significantly influenced user behavior, purchaser choices (as, for example, in available options), and use of protective equipment. Warnings are an important liability prevention and design safety objective.

## 20.3 Bioengineering

---

*Jeff R. Crandall, Gregory W. Hall, and Walter D. Pilkey*

The interdisciplinary field of **bioengineering** combines personnel and principles from the physical and life sciences. Although a relatively young field, it is developing rapidly by incorporating experimental and computational techniques from traditional disciplines of engineering and applying them to biological problems. In particular, finite-element techniques and computer modeling are revolutionizing the manner in which bioengineering is conducted and interpreted.

Although based on the principles of traditional disciplines, bioengineering differs from classical engineering because the human body is a living system capable of responding to a changing environment. This results in several challenges for the bioengineer:

- Material properties can vary due to intrinsic and extrinsic factors, e.g., physical properties change with specimen age, gender, and health;
- The human body is capable of self-repair and adaptation, e.g., muscle size increases in response to physical training;
- Many structures within the body cannot be isolated for laboratory testing, e.g., the heart cannot be removed to study circulatory system mechanics.

The discipline of bioengineering includes, but is not limited to, the topics of

- Biomechanics
- Biomaterials
- Biomedical instrumentation and sensors
- Biotechnology
- Genetic engineering
- Medical imaging
- Clinical engineering.

Due to the vast breadth of the field, the authors of this section have not attempted to provide an exhaustive overview of the field of bioengineering but rather have tried to select those areas believed to be of most interest to mechanical engineers. Therefore, this summary of bioengineering is intended to acquaint the reader with the concepts and terminology within the fields of **biomechanics** and **biomaterials** and to provide basic material properties for both tissues and implanted devices.

### Biomechanics

The field of biomechanics applies the theories and methods of classical mechanics to biological systems. More precisely, it is concerned with the forces that act on and within a biological structure and with the effects that these forces produce. An overview of topics within the field of biomechanics is provided in [Figure 20.3.1](#). It is evident that the study of stress and strain distributions in biological materials for the development of constitutive equations is a major research emphasis. A review of the constitutive equations and the associated material properties are provided in this section for the most commonly tested tissues.

### Hard Tissue Mechanics

The term *bone* refers to two types of hard tissue structure: cortical and cancellous bone. Cortical bone is the dense, structured compact bone that composes the shaft of long bones such as the femur and tibia. Cancellous or trabecular bone is found within the ends of tubular bones and the body of irregularly shaped bones. The mechanical and structural properties of the two types of bone can vary substantially. In addition, bone is capable of **remodeling** in response to its environment. [Table 20.3.1](#) summarizes the general physical and material properties for the two bone types.

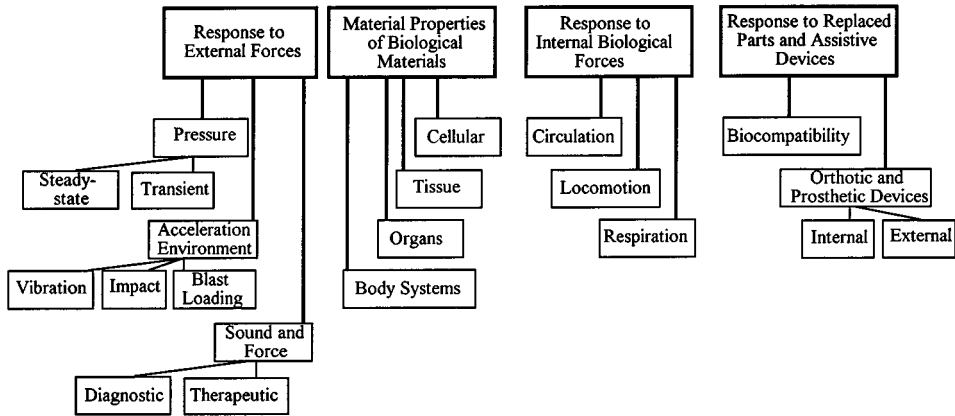

FIGURE 20.3.1 Topics of biomechanics.

TABLE 20.3.1 Physical and Material Properties of Cancellous and Cortical Bone

Bone	Density (kg/m <sup>3</sup> )	Poisson's Ratio	Elastic Modulus (GPa)	Tensile Strength (MPa)	Compressive Strength (MPa)	Ref. <sup>a</sup>
Cortical	1700–2000	0.28–0.45	5–28	80–150	106–224	1
Cancellous	100–1000	—	0.1–10	—	1–100	2

<sup>a</sup> 1, Nigg and Herzog (1994); 2, Mow and Hayes (1991).

Like most biological materials, bone behaves as an anisotropic, nonhomogeneous, viscoelastic material. Therefore, the values in Table 20.3.1 exhibit a wide range of scatter and variability due to the simplified model of bone as a linearly elastic isotropic material. It is generally adequate, however, to model bone as a linearly elastic anisotropic material at the strain rates found in most experiments. To address the anisotropy of bone, bone is generally considered to exhibit either transverse isotropic or orthotropic behavior. The constitutive equation for a linearly elastic material can be written using a single-index notation for stress and strain as

$$\sigma_i = c_{ij} \epsilon_j \tag{20.3.1}$$

where the standard summation convention is used with the indexes possessing a range of 6. The stress-strain relationship can be similarly expressed in terms of the compliance matrix  $s_{ij}$  such that

$$\epsilon_i = S_{ij} \sigma_j \tag{20.3.2}$$

Equation (20.3.3) represents the compliance matrix of an orthotropic material in terms of the Young's moduli ( $E_i$ ), the Poisson's ratio ( $\nu_{ij}$ ), and the shear moduli ( $G_{ij}$ ).

$$S_{ij} = \begin{bmatrix} 1/E_1 & -\nu_{21}/E_2 & -\nu_{31}/E_3 & 0 & 0 & 0 \\ -\nu_{12}/E_1 & 1/E_2 & -\nu_{32}/E_3 & 0 & 0 & 0 \\ -\nu_{13}/E_1 & -\nu_{23}/E_2 & 1/E_3 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1/G_{23} & 0 & 0 \\ 0 & 0 & 0 & 0 & 1/G_{31} & 0 \\ 0 & 0 & 0 & 0 & 0 & 1/G_{12} \end{bmatrix} \tag{20.3.3}$$

For an orthotropic material the compliance matrix can be expressed in terms of 12 components, 9 of which are independent. The additional symmetry of the transverse isotropic model results in a further simplification with

$$E_1 = E_2, \quad \nu_{12} = \nu_{21}, \quad \nu_{13} = \nu_{31}, \quad G_{23} = G_{31}$$

$$G_{12} = \frac{E_1}{2(1 + \nu_{12})} \quad (20.3.4)$$

Table 20.3.2 provides a summary of the material constants for bone. Both mechanical and ultrasonic testing have been used to determine the independent elastic coefficients for bone. The anisotropy of bone requires that mechanical tests be applied in several different directions in order to determine all of the independent elastic coefficients. Ultrasound has the advantage that all elastic coefficients can be measured on a single specimen.

**TABLE 20.3.2 Material Constants for Cortical Bone from the Human Femur**

Model	$E_1$ (GPa)	$E_2$ (GPa)	$E_3$ (GPa)	$G_{12}$ (GPa)	$G_{13}$ (GPa)	$G_{23}$ (GPa)	$\nu_{12}$	$\nu_{13}$	$\nu_{23}$	$\nu_{21}$	$\nu_{31}$	$\nu_{32}$
TI	11.5	11.5	17.0	3.6	3.3	3.3	0.58	0.31	0.31	0.58	0.46	0.46
Orth.	12.0	13.4	20.0	4.53	5.61	6.23	0.376	0.222	0.235	0.422	0.371	0.350

Note: TI = transverse isotropic; Orth. = orthotropic.

## Mechanics of Soft Tissue

The biomechanical properties of soft tissues depend on both the chemical composition and the structure of the tissue. Most soft tissue structures within the body demonstrate aspects of nonhomogeneous, anisotropic, nonlinear viscoelastic behavior. Given the complexity of the constitutive equations, the material properties are difficult to measure and many tests are required. To simplify the test procedures, homogeneity and linearity are frequently assumed.

The simplest representation of viscoelastic material behavior uses combinations of three discrete models comprising linear springs and dashpots: the Maxwell solid, the Voigt model, and the Kelvin model. While these models are generally linear approximations of the nonlinear behavior of biological materials, they can often describe material behavior with reasonable accuracy and can help to visualize tissue behavior.

For improved characterization of the soft tissue response, Fung (1993) developed an approximate theory that was based on the theory of linear viscoelasticity but incorporated nonlinear stress-strain characteristics. More-complex nonlinear viscoelastic models can provide additional improvements in describing tissue response but require extensive experimental testing to determine the model coefficients.

## Cartilage

In most joints of the body, the ends of the articulating bones are covered with a dense connective tissue known as hyaline articular cartilage. The cartilage is composed of a composite organic solid matrix that is swollen by water (75% by volume). The cartilage serves to distribute load in the joints and to allow relative movement of the joint surfaces with minimal friction and wear. The coefficient of friction for articular cartilage ranges from 0.001 to 0.1 (Duck, 1990; Mow and Hayes, 1991).

The biomechanical properties of articular cartilage are summarized in Table 20.3.3. The experiment of preference for the testing of articular cartilage has historically been the indentation test. Analysis of the test results has used elastic contact theory, the correspondence principle, and the assumption of material incompressibility ( $\nu = 0.5$ ). This analysis ignores the nonhomogeneous and directional properties of articular cartilage and does not take into account considerable finite deformational effects or the flow

**TABLE 20.3.3 Biomechanical Properties of Articular Cartilage**

Tissue	Ultimate Compressive Strength (MPa)	Ultimate Compressive Strain	Ultimate Tensile Strength (MPa)	Ultimate Tensile Strain	Elastic Modulus (MPa)	Poisson's Ratio	Ref. <sup>a</sup>
Cartilage	5.0–8.0	0.136	2.8–40	0.182	1.63–220	0.42–0.47	1, 2, 3

<sup>a</sup> 1, Duck (1990); 2, Skalak and Chien (1987); 3, McElhaney (1976).

of the interstitial fluid relative to its porous permeable solid matrix. More-recent models of cartilage have used a biphasic (i.e., an elastic solid and a fluid phase) model to describe more accurately the mechanical response of cartilage.

**Muscle**

Three types of muscle make up the muscular system: cardiac muscle, smooth or involuntary muscle, and skeletal or voluntary muscle. The focus of this section will be on the skeletal muscle used to maintain the body’s posture and to provide movement of the body’s segments. The response of skeletal muscle is determined by a combination of active and passive components. The force exerted by a muscle is dependent on the length at which it is stimulated, on the velocity of contraction, on the duration of contraction, and on factors such as fatigue, temperature, and prestretching. A general estimate of the strength of the muscle assumes that its strength is proportional to the physiological cross-sectional area, defined as the muscle volume divided by its true fiber length. The average unit force per cross-sectional area that is exerted by a muscle ranges from 20 to 80 N/cm<sup>2</sup>. For more-precise calculations, the relationship between the maximum force of muscle and instantaneous rate of change of its length must be considered. Hill’s equation is an empirical relationship expressing the rate of muscle shortening as a function of the isotonic force

$$V = \frac{b(F_0 - F)}{F + a} \quad \text{or} \quad F = \frac{F_0 b - av}{b + v} \tag{20.3.5}$$

where  $v$  is the velocity of shortening,  $F_0$  is the force at zero velocity (isometric condition), and  $F$  is the instantaneous force. The constants  $a$  and  $b$  have units of force and velocity, respectively, determined empirically using the relationship

$$K = \frac{a}{F_0} = \frac{b}{V_{\max}} \tag{20.3.6}$$

where  $v_{\max} = bF_0/a$ , the shortening velocity against no load. For most muscles, the range of the muscle constant is  $0.15 < k < 0.25$  (Skalak and Chien, 1987).

**Tendon/Ligaments**

Tendons and ligaments are connective tissues composed primarily of collagen fibers and are normally loaded in tension. Tendons transmit forces from muscles to bone in order to

- Execute joint motion and
- Store energy.

Ligaments attach articulating bones across a joint in order to

- Guide joint movement;
- Limit the joint range of motion;

- Maintain joint congruency; and
- Assist in providing joint stability.

The biomechanical properties of ligaments and tendons are provided in [Table 20.3.4](#).

**TABLE 20.3.4 Biomechanical Properties of Tendon and Ligament**

Tissue	Ultimate Tensile Strength (MPa)	Ultimate Tensile Strain	Elastic Stiffness (MPa)	Ref. <sup>a</sup>
Ligament	2.4–38	0.20–1.60	2–111	1, 2, 3
Tendon, calcaneal	30–60	0.09–0.10	600	4, 5

<sup>a</sup> 1, Yamada (1970); 2, Skalak and Chien (1987); 3, Nahum and Melvin (1993); 4, Bronzino (1995); 5, Duck (1990).

The general stress-strain behavior of connective soft tissue can be represented by four distinct loading regions ([Figure 20.3.2](#)). Region I is commonly referred to as the “toe region” and is associated with the straightening or alignment of the randomly ordered structural fibers. Most physiological loading occurs in this region where there is a small increase in stress for a given increase in strain. Region II characterizes the linear region where the straightened fibers are more uniformly loaded. The tangent to the stress-strain response curve in this linear region is frequently referred to as the elastic stiffness or tangent modulus rather than the elastic modulus in order to emphasize that the soft tissue is not truly behaving as a perfectly elastic material. At the initiation of Region III, small fluctuations in the stress can be observed resulting from microfailures in the soft tissue. The final loading profile shown in Region IV exhibits catastrophic failure of the soft tissue.

**FIGURE 20.3.2** General stress-strain behavior of connective soft tissue.

### Factors Affecting Biomechanical Properties

Due to the nature of biological testing, a great deal of variability in the material properties of tissue is evident in the published literature. Unlike traditional engineering materials, there are no standard protocols or procedures for the testing of biological materials. Although some variability can be attributed to differences in the experimental approaches undertaken by the researchers, mechanical behavior of biological materials can also be affected by

- Geometric characteristics;
- Loading mode (i.e., tension, compression, torsion);
- Rate and frequency of loading;
- Specimen preparation (i.e., temperature, preservation method, hydration);
- Age or health of specimen donor;
- Gender;
- Temperature;
- Anatomic location of load and specimen;
- Species.

*Rate of Loading.* The rate of load can affect both the material properties and the patterns of failure of biological materials. Due to their viscoelastic nature, many biological materials are stronger and stiffer at high rates of loading.

*Loading Mode.* The stress-strain behavior of biological materials is highly dependent on the orientation of the tissue structure with respect to the direction of loading (Table 20.3.5). Many tissues such as cortical bone, tendon, and muscles have organized structures which result in anisotropy of the physical properties. In some cases, the anisotropy exists but is not incorporated in the constitutive model or experiments and results in increased variability of the data.

**TABLE 20.3.5 Material Properties Variation in Bone Due to Specimen Orientation and Loading Mode**

Cortical Bone Orientation	Mode	Ultimate Strength (MPa)	Elastic Modulus (MPa)	Ref.
Longitudinal	Tension	133	—	Currey (1984)
	Compression	193	17	
	Shear	68	3.3	

*Anatomic Location.* Although homogeneity is often assumed, biological tissues typically exhibit significant differences in material properties depending on the anatomic location. Table 20.3.6 illustrates the variability of material properties with anatomic location using articular cartilage from the knee.

**TABLE 20.3.6 Dependence Tensile Modulus (E) of Human Articular Cartilage on Location**

Region	Medial Anterior	Medial Central	Medial Posterior	Lateral Anterior	Lateral Central	Lateral Posterior	Ref.
E (MPa)	159.6	93.2	110.2	159.1	228.8	294.1	Mow and Hayes (1991)

*Age.* The material properties of biological materials can vary depending on whether the specimens are obtained from immature, mature, or aging tissue. In general, the ultimate strength of tissues decreases with increasing age. Bone, muscle, tendon, cartilage, and ligaments all show decreases in the ultimate strength and elastic moduli after maturity with increasing age (Table 20.3.7). Several tissues, such as skin and teeth, are exceptions to this general rule and can exhibit increases in some material properties with age.

**TABLE 20.3.7 Ratio of Age Changes for Ultimate Tensile Strength**

Tissue	10–19years	20–29years	30–39years	40–49years	50–59years	60–69years	70–79years
Cortical bone	0.93	1.00	0.98	0.91	0.76	0.70	0.70
Cartilage	1.02	1.00	0.93	0.80	0.56	0.33	0.29
Muscle	1.27	1.00	0.87	0.73	0.67	0.60	0.60
Tendon	1.00	1.00	1.00	1.00	1.00	0.95	0.78
Skin	—	1.00	1.26	1.26	1.08	0.96	0.77

*Storage/Preservation.* The increasing complexity of biomechanical testing requires a considerable period of time for each individual test and necessitates tissue storage and preservation. It is essential to ensure that the storage and preservation of biological materials is controlled so that the material property measurements in the laboratory accurately reflect the properties of the tissue in the living state. Biological materials are preserved using one of three methods depending on the required storage interval:

- Refrigeration for short-term storage;
- Freezing for long-term storage;
- Embalming for long-term storage.

Refrigeration and freezing have no effect on the properties of hard tissue. Although the effects of refrigeration on soft tissue properties are tissue dependent, stable properties can generally be achieved within 3 days of storage. Freezing of soft tissue can result in ice cavities that disrupt the tissue architecture and result in property changes. The effects of embalming on soft and hard tissue structures exhibit conflicting results.

Because many biological materials are composed primarily of water, humidity can strongly affect the stress-strain relationships (Table 20.3.8). Therefore, care must be taken to keep biological specimens moist prior to and during testing. The control of the moisture level of specimens is most important when analyzing the elastic properties of surface tissues such as skin and hair. Young's modulus of skin at 25 to 30% relative humidity may be 1000-fold greater than that at 100% humidity (Duck, 1990).

**TABLE 20.3.8 Comparison of Material Properties between Wet and Dry Cortical Bone**

Test Condition	Ultimate Tensile Strength (kg/mm <sup>2</sup> )	Ultimate Percentage Elongation (%)	Elastic Modulus (kg/mm <sup>2</sup> )	Ref.
Wet tibia	14.3 ± 0.12	1.50	1840	Yamada (1970)
Dry tibia	17.4 ± 0.12	1.38	2100	Yamada (1970)

*Species.* Animal tissues have been used extensively in biomechanical testing because of their availability. When extrapolating results to humans, care must be taken since significant differences can exist in the structure and material properties between humans and other animals due to physiological and anatomic differences. Table 20.3.9 shows a comparison of elastic moduli of femoral bone specimens obtained from different animals.

**TABLE 20.3.9 Comparison of Bone Elastic Modulus between Different Species**

Tissue Source	Tissue	Elastic Modulus (MPa)	Ref.
Human	Femur	18	Currey (1984)
Cow	Femur	23	
Sheep	Femur	22	
Tortoise	Femur	10	

## Impact Biomechanics

The prevention of injury through the development of countermeasures is most effectively achieved through biomechanical testing and analysis. The prevalence of injuries resulting from motor vehicle crashes, sporting activities, and industrial accidents has led to the development of a branch of biomechanics referred to as impact biomechanics. In order to achieve the principal aims of prevention of injury through environmental modification, this branch of biomechanics must develop an improved understanding of the mechanisms of injury, descriptions of the mechanical response of the biological materials involved, and information on the human tolerance to impact. Injury criteria for the human body as interpreted by anthropometric dummies are provided in Table 20.3.10. The injury criteria are provided in terms of engineering parameters of resultant acceleration  $a(t)$ , force  $F(t)$ , velocity  $V(t)$ , displacement  $s(t)$ , and anthropometric scaling factors such as the chest depth  $D$ .

## Computational Biomechanics

Computational mechanics provides a versatile means of analyzing biomechanical systems. Modeling uses either rigid-body models composed of rigid masses, springs, joints, and contact surfaces or flexible-

**TABLE 20.3.10 Adult Midsize Male Injury Criteria for an Impact Environment**

Body Region	Injury Criteria	Formulation	Threshold
Head	Head injury criteria (HIC)	$HIC = (t_2 - t_1) \left[ \frac{1}{(t_2 - t_1)} \int_{t_1}^{t_2} a(t) dt \right]^{2.5}$	1000
Chest	Compression criteria	$s(t)$	7.5 cm
	Acceleration criteria	$a(t)$	65 g
	Viscous criteria ( $V * C$ )	$V(t) * s(t)/D$	1 m/sec
Femur	Force criteria	$F(t)$	10 kN

**TABLE 20.3.11 Comparison of Rigid Body and Finite Element Modeling Methods**

Model Characteristics	Multibody Model	Finite-Element Method
Complexity	Relatively simple	Relatively complex
Fidelity	Requires engineering intuition	Can achieve high fidelity
Efficiency	Very efficient	Computationally expensive
Model Elements	Springs, point masses, rigid bodies, ellipsoids, joints, and contact planes	Flexible elements: bricks, beams, plates, shells

body models with finite or boundary elements (Table 20.3.11). Software is now available that incorporates the two modeling techniques and uses multibody modeling to capture overall kinematics of a biomechanical system and flexible body modeling to provide an in-depth study of those regions of particular interest.

The complexity of biological systems and limited constitutive model data often require that simplifying assumptions be made during the development of models. Therefore, it is necessary to verify the model before conducting parametric and sensitivity studies.

### Biomaterials

The application of engineering materials to replace, support, or augment structures in the human body has become a major thrust of medical research in the last half of the 20th century. These efforts have helped to improve quality of life and longevity in individuals suffering from a variety of diseases and injuries. Since the materials involved with this repair are implanted within the biochemically and mechanically active environment of the body, the response of both the host and material has been investigated.

A biomaterial is defined as a nonviable material used in a medical device that is intended to interact with biological systems. The interaction of a biomaterial with its host can be classified into four categories (Black, 1992):

- *Inert* — implantable materials which elicit a minimal host response.
- *Interactive* — implantable materials which are designed to elicit specific, beneficial responses, such as ingrowth and adhesion.
- *Viable* — implantable materials, possibly incorporating live cells at implantation, which are treated by the host as normal tissue matrices and are actively resorbed and/or remodeled.
- *Replant* — implantable materials consisting of native tissue, cultured *in vitro* from cells obtained previously from the specific implant patient.

The concept behind *inert* implants is to introduce an “innocuous” implant to the host that will perform its mechanical role without altering the local environment. Decades of research on host and implant response have informed the biomedical community that no implant is inert and that every material will elicit a response from the host. For many biomaterial applications, the objective is to elicit a *minimal*

host response. Those implants that are *interactive* with the biological environment do so in a desired and planned fashion. *Viable* implants are at their infancy, but already show promise in assisting and possibly directing tissue repair. The concept of an entire organ *replant* is still unrealized, but current strides in deciphering the human genetic code will make replants of **autologous** materials a clinical method of the future.

### Material and Host Response

*The Physiological Environment.* The first reaction of the body to an implant is to “wall off” or build a fibrous tissue capsule around the implant. The biomaterial will be enclosed in a fibrous capsule of varying tissue thickness that will depend on the material and the amount of motion between the tissues and the implant. When the biomaterial elicits a minimal encapsulating response, it is possible for the tissue to integrate with the implant mechanically. This has been demonstrated in total-joint replacement when new bone is formed to interdigitate with a porous surface. Another approach to **biocompatibility** has been to use the tissue response to a material to benefit the function of the implant. This approach is used when bone chemically bonds to the hydroxyapatite coatings on hip implants.

The interaction between implant material and the host occurs at both the chemical and mechanical level. There are several parameters that affect the response of the biomaterial to the host environment and the overall performance:

- *The pH and salt content of the implant site* — A Pourbaix diagram for saline environments should be consulted to see if the metal will be passivated.
- *Lipid content of the implant site* — Lipophilic materials may swell or lose strength.
- *Mechanical environment* — Implant materials may wear, creep, and/or fatigue.
- *Corrosive potential of the material* — Metallic implants are susceptible to galvanic, crevice, and other types of corrosion.
- *Method of manufacture and handling* — Scratches and other defects will increase the likelihood of crack development and/or crevice corrosion.
- *Method of sterilization* — Some methods of sterilization will cross-link polymers or affect the degradation of biodegradable materials.

The host response to an implanted material is also affected by both chemical and mechanical factors. A few parameters that affect host response are

- *Leached materials from the implant* — Leached material, consisting of metallic ions, polymeric molecules, or solvents from manufacturing, may denature proteins. The pathway and effects of leached material should be examined.
- *Surface tension and electric charge of the material.*
- *Stiffness of the biomaterial* — Stress shielding of the bone by a stiff implant has been shown to affect bone remodeling.
- *Geometry of the implant* — Sharp edges have been shown to increase the fibrous tissue capsule thickness.
- *Method of cleaning and sterilization* — Solvents, filings, or residues left from the manufacturing, handling, or sterilization processes will likely cause unwanted host response and increase the probability of infection.

The expected life span of an implant varies with application. Some implants are used for temporary structural support, such as intermedullary nails for fracture fixation. In this application, corrosion is not as critical an issue as cost and mechanical fatigue. Another approach to temporary applications has been the use of biodegradable materials that eventually dissolve into the body. Biodegradable materials have been used for fracture fixation and drug delivery with success.

### Current Biomaterials

**Metallic Biomaterials.** Metals are typically selected for biomedical applications because of their high tensile strength (Table 20.3.12). With the high tensile strength of metals comes a high elastic modulus that can lead to stress shielding of the bone. Bone, which remodels in response to its loading environment, resorbs in regions of low stress which can lead to implant loosening.

**TABLE 20.3.12 Common Metallic Biomaterials**

Metal	Form	Density (g/cm <sup>3</sup> )	E Modulus (GPa)	Yield Strength (MPa)	Fatigue Strength @ 10 <sup>7</sup> Cycles (MPa)	Characteristics	Medical Applications	Ref. <sup>a</sup>																																	
Ti-6Al-4V	AN	4.4	127	830–896	620	Chemically inert, poor wear properties, good fatigue properties, high strength-to-weight ratio, closest modulus to that of bone	Total hip and knee stems	1, 5

<sup>a</sup> 1, ASTM F136-79; 2, ASTM F75-82; 3, ASTM F90-82; 4, ASTM F560-86, p. 143, 1992; 5, Green and Nokes (1988); 6, ASTM F55-82; 7, Smith and Hughes (1977).

Another issue when using metals in the body is corrosion since very few metals are in a passivated state while *in vivo*. Metallic implant materials are subject to several types of corrosion: galvanic, crevice, pitting, intergranular, and stress/fatigue. For metallic biomaterial selection, it is best to refer to the corrosion potential of a material in seawater, rather than tap water since seawater is a reasonable approximation for the *in vivo* environment. Implant designs that involve dissimilar metals or multiple pieces have increased susceptibility to galvanic corrosion (Cook et al., 1985). A reasonable prediction of the reactivity between dissimilar metals can be made upon consideration of the galvanic series.

**Polymers.** The number of polymers available for biomedical applications has been increasing rapidly in the last few decades. Polymers are viscoelastic materials whose mechanical properties, host response, and material response depend on molecular weight, degree of cross-linking, temperature, and loading rate, among other factors. Therefore, it should be recognized that tabular data representing the mechanical properties of polymers only indicates the general range of properties for a class of polymers (Tables 20.3.13 and 20.3.14). Common applications of polymers in biomedical engineering include articular wear components, drug-delivery devices, cosmetic augmentation, blood vessels, and structural applications.

**Biodegradable Polymers.** There are a plethora of degradable polymers available to the modern biomedical engineer. Each is unique in mechanical properties, degradation time, degradation products, and sensitivity of strength to degradation. Recent efforts in polymer development have focused on biodegradable materials that serve as either temporary support or drug-delivery devices during the healing

TABLE 20.3.13 Bulk Material Properties of Some Thermoset Polymers

Thermoset	Density (g/cm <sup>3</sup> )	Modulus (GPa)	Yield Strength (MPa)	Ultimate Strength (MPa)	Elongation (%)	Applications	Comments	Ref. <sup>a</sup>
Polyethylene terephthalate (dacron, polyester)	1.40	2.41	62.06	150–250	70–130	Suture, mesh, vascular grafts, heart valves, fluid transfer implants, artificial tendons	Subject to negligible creep, heat resistance up to 250°F, steam sterilizable, poor wear resistance, susceptible to hydrolysis and loss of strength	1, 2
PMMA thermoset	1.15–1.20	2.4–3.1	15.8	9.7–32	2.4–5.4	Acrylic bone cement	Very biologically inert, poor tensile strength, monomer lowers blood pressure, may cause thermal necrosis during curing at 95°C, radiolucent without addition of barium sulfate	2, 3
Polyurethane	1.10	5.9	—	45	750	Implant coatings	Good resistance to oil and chemicals	2
Silicone Rubber						Cosmetic augmentations, nose, ear, chin, and breast implants	Polymer backbone is silicon, rubbery mechanical properties, lipophylic, material elicits a minimal host response and has very flexible, cartilage-like stiffness, may cause local sclerosis and inflammatory phenomena. Recent <i>in vitro</i> studies on silicone have demonstrated an absence of cytotoxic response. There is no current epidemiological data to support termination of its use	2, 4, 5
Heat vulcanized	1.12–1.23	<1.4	—	5.9–8.3	350–600			
High performance	0.98–1.15	2.4	—	8.3–10.3	700

process. One of the primary advantages to the use of biodegradable implants and suture is that they do not require surgical removal. This aspect decreases both the risk of infection and cost. The main mechanism of *in vivo* degradation is hydrolytic degradation, although some enzymes may also serve a role (Piskin, 1995). For use of these biomaterials, an in-depth knowledge of the candidate polymer is recommended. A basic description of several degradable polymers is provided in [Table 20.3.15](#).

**Ceramics.** Ceramic materials are some of the strongest and hardest material structures used in engineering. Ceramics are composed of primarily inorganic compounds and are generally characterized by unstable crack growth that leads to poor tensile strength ([Table 20.3.16](#)). There are two categories of ceramic biomaterials: relatively inert and **bioactive**. Relatively inert ceramics have high compressive strength and hardness and are commonly used for wear applications. Bioactive ceramics are designed to bond with the host tissue and do not possess great strength characteristics ([Table 20.3.17](#)).

Optimum biocompatibility of ceramic degradable biomaterials occurs only with special proportions of the material constituents. Unfortunately, the confines of these proportions limit the mechanical properties of the material. These materials are not strong enough for structural applications, but have been successfully used as coating material to enhance tissue bonding, as dental restorative material, and as filler in bone cement (Bajpai and Billotte, 1995).

**Composite Biomaterials.** Composite biomaterials combine the properties of two or more different materials in order to obtain a biomaterial with tailored properties. With composite biomaterials, the opportunity exists to fabricate an implant that is stronger and lighter than conventional implants while exhibiting a stiffness that is very similar to surrounding tissues. The material properties of composite materials depend on the matrix material, reinforcement material, volume fraction of reinforcement material, interfacial bond strength, orientation of reinforcement, number of inclusions, and other factors. Use of composite biomaterials is in its infancy but has already been used to improve the strength, stiffness, and toughness in current biocompatible materials.

In biodegradable composite materials, the method used to acquire final implant geometry will affect the service life of the implant. Machining has been shown to expose fiber ends on the surface and to promote the wicking of surrounding fluid into the device, which can increase the rate of degradation.

**Materials of Natural Origin.** Materials from natural origin may be xenogenous (i.e., obtained from other species) or autogenous (i.e., obtained from the patient). Xenogenous biological materials from nonhuman animals are commonly used for soft tissue replacement. These materials exhibit mechanical properties that are very similar to the surrounding living human tissue but may cause an immune response due to their non-self proteins. Examples of a xenogenous biomaterial are the porcine heart valve, cat-gut suture, and collagen-based implants. Recent research on heart and kidney transplants from primates have demonstrated the feasibility of using living xenogenous biomaterials.

**TABLE 20.3.16 Material Properties of Relatively Inert Biomedical Ceramics**

Material	Density (g/cm <sup>3</sup> )	Grain Size (nm)	E Tensile Modulus (GPa)	Hardness (HV) (N/mm <sup>2</sup> )	Fatigue Strength (MPa)	Comments	Applications	Ref. <sup>a</sup>
Alumina (AL <sub>2</sub> O <sub>3</sub> )	3.9–4	3000–4000	380	23,000	550	Very inert, excellent wear and friction properties, may increase tissue aluminum causing bone demineralization	Articular bearing surfaces, dental implants, total joint prostheses	1, 2, 6–8
LTI carbon	1.7–2.2	3–4	18–28	150–250	280–560	Excellent blood compatibility, low density	Coating or structural material for heart valves and blood vessels	3
Vitreous carbon	1.4–1.6	1–4	24–31	150–200	70–210	Known as glassy carbon due to lack of crystal structure	Artificial heart valves	3
Zirconia (ZrO <sub>2</sub> )	6.1	<0.5	200	16,000	1200	Nonreactive in rhesus monkey bone <i>in vivo</i> , excellent wear and friction properties	Articular bearing surfaces	4, 5, 8

**TABLE 20.3.17 Bioactive Ceramic Materials**

Material	Chemical Content	Comments	Ref. <sup>a</sup>
Hydroxyapatite	Ca <sub>10</sub> (PO <sub>4</sub> ) <sub>6</sub> (OH) <sub>2</sub>	Actual mineral phase of bone, used as a coating or solid, synthetic versions available, good mechanical properties, excellent biocompatibility, subject to osteoclastic resorption, chemically bonds to bone	1, 2
Bioglass 46S5.2	46.1% SiO <sub>2</sub> , 26.9% CaO, 24.4% Na <sub>2</sub> O, 2.6% P <sub>2</sub> O <sub>5</sub> mol%	Fine-grained, glassy ceramics, 46S5.2 exhibits best tissue bonding, other constituent ratios are available	3, 4
Ceravital	Bioglass materials with Al <sub>2</sub> O <sub>3</sub> , TiO <sub>2</sub> , and Ta <sub>2</sub> O <sub>5</sub> added	Very similar composition to bioglass with additional metal oxides to control dissolution rate	4

<sup>a</sup> 1, Gessink et al. (1987); 2, Kay (1988); 3, Hench and Ethridge (1982); 4, Bajpai and Billotte (1995).

Autogenous materials are used when skin and bone are relocated on a patient. As human ability to manipulate the human genetic code continues, it may be possible to replace failed human organs with identical organs that have been grown either *in vitro* or *in vivo*.

### Biomaterial Testing

The human body is a biologically and mechanically active environment that reacts to all materials. Biomaterials should be initially selected for their engineering mechanical properties to serve a specific function. Careful consideration must be given to the fatigue and creep properties of the material because of the rigorous loading incurred by many implants. The anterior cruciate ligament of a moderately active person, for example, will be subjected to 4.2 million loading cycles annually (Black, 1992). This frequency of cyclic loading is consistent with the cyclic loading of other orthopedic structures.

Once a candidate material has been selected, the material must be tested to determine both the material response to its proposed biological environment and the host response to that material. Valuable host and material response information may be obtained from the use of *in vitro* tests that simulate a specific physiological environment. The final step before implantation into a human is to test the performance of a candidate material with an animal model.

*In Vitro Studies.* Experimental *in vitro* studies should be conducted prior to testing on living animals. *In vitro* studies provide essential information on the response of the candidate biomaterials to a simulated host environment and on the chemical interactions that ensue. It is important to observe the effect of the biomaterial on proteins to determine if any coating, denaturing, or other processes result. These studies are inexpensive and can be tailored to simulate specific implant sites. Initial tests may simply expose the candidate material to the expected inorganic chemical and thermal conditions. More complex *in vitro* tests may include appropriate, viable, active cells with their associated cell products. The cell survival count, reproduction rate, metabolic activity, effective motion activity, and cell damage should be observed during testing (Black, 1992). Some sample *in vitro* materials tests are described in [Table 20.3.18](#).

Biomaterials intended for vascular applications must be tested for their interaction with blood. Examination of blood-biomaterial interactions should include protein absorption, platelet interactions, intrinsic coagulation, fibrinolytic activity, erythrocytes, leukocytes, and complement activation. Since the circulatory system has both an oxygen- and nutrient-rich arterial side and a carbon dioxide-rich venous side, a candidate material must be tested in the environment for which it is intended.

*In Vivo Studies.* Animal studies are extremely valuable for examining the host and material response of a specific test material. These studies must be in complete accordance with the Animal Welfare Act (7 U.S.C. 2131, December 23, 1985). Initial animal tests are nonfunctional and involve placing a test specimen in an anatomic location similar to the expected implant location. These locations may be subcutaneous, intramuscular, intraperitoneal, transcortical, or intramedullary. Depending on the study, the duration of implantation can vary from weeks to years. Factors that affect the outcome of nonfunctional

TABLE 20.3.18 Sample *In Vitro* Tests

<i>In Vitro</i> Test	Brief Description
ASTM F895-4 cytotoxicity	Place sterile agar over mouse fibroblast cells. Place the test material on top and incubate for 24 hr; examine the culture for the extent of cell lysis
Ames test for mutagenicity	Expose autotrophic <i>Salmonella typhimurium</i> bacteria cells to the test material and histidine for 48 hr at 37°C; if cells mutate to non-autotrophic state, histidine levels will be lower after testing
Lee-White coagulation rate	Place a small volume of fresh-drawn blood on a test surface and similar amount on control surface; compare coagulation times
<i>Ex vivo</i> blood compatibility	Tap into the bloodstream of a canine; let blood flow at typical rates and pressure through a test specimen for a short time; examine specimen for platelet adhesion and blood for hemolysis

tests include the degree of relative motion between implant and host and the geometry of the test specimen.

Functional testing of biomedical materials is performed in order to evaluate a test material or design as it performs its intended function. Species are selected for an animal model based on similarities with human models and then scaled to size. Some factors to consider are the life span, activity level, metabolic rate, and size of the test animal. Results are determined from macroscopic and histological evaluations.

## Defining Terms

**Autologous:** Related to self; materials obtained from the same organism.

**Bioactive:** The ability of a material to chemically interact with the host environment in a predetermined manner.

**Biocompatibility:** The ability of a biomaterial to perform with an appropriate host response in a specific manner.

**Bioengineering:** The application of principles from engineering, applied mathematics, and physics to the study of biological problems.

**Biomaterial:** A nonviable material used in a medical device that is intended to interact with biological systems.

**Biomechanics:** The study of forces that act on and within a biological structure and the effects that these forces produce.

***In vitro*:** Within a glass; observable in an artificial environment such as a test tube.

***In vivo*:** Within the living body.

**Remodeling:** Changes in internal architecture and external conformation of biological tissues in accordance with applied strain.

**Sterilization:** The complete elimination or destruction of all living microorganisms. The most common methods are steam, radiation, and chemical sterilization.

## Further Information

A comprehensive summary of the biomechanical properties of tissues can be found in the *Strength of Biological Materials* (Yamada, 1970). A good introduction to material response, material testing, and host response is presented in *Biological Performance of Materials; Fundamentals of Biocompatibility* (Black, 1992).

A reference that goes more in-depth on biomaterial chemical contents, applications, and manufacturing is *The Biomedical Engineering Handbook*, edited by Joseph Bronzino (1995).

The *Journal of Biomedical Materials Research* is a monthly publication that reports advancements in the field of biomaterial development and testing. For subscription information contact: Journal of Biomedical Materials Research, Subscription Fulfillment and Distribution, John Wiley and Sons, Inc., 605 3rd Avenue, New York, NY 10158.

The *Journal of Biomechanics* covers a wide range of topics in biomechanics, including cardiovascular, respiratory, dental, injury, orthopedic, rehabilitation, sports, and cellular. For subscription information, contact: Elsevier Science, Inc., 660 White Plains Road, Tarrytown, NY 10591-5153.

## 20.4 Mechanical Engineering Codes and Standards

---

*Michael Merker*

### What Are Codes and Standards?

A **standard** can be defined as a set of technical definitions, requirements, and guidelines for the uniform manufacture of items; safety, and/or interchangeability. A **code** is a standard which is, or is intended to be, adopted by governmental bodies as one means of satisfying legislation or regulation. Simply put, they can range from a general set of minimum requirements to very specific “how to” instructions for designers and manufacturers.

Voluntary standards, and they can run from a few paragraphs to hundreds of pages, are written by experts who sit on the many committees administered by standards-developing organizations (SDOs), such as ASME International.

They are not considered voluntary because they are created by volunteers; rather they are voluntary because they serve as guidelines, but do not of themselves have the force of law. ASME International publishes its standards; accredits users of standards to ensure that they have the capability of manufacturing products that meet those standards; and provides a stamp that accredited manufacturers may place on their product, indicating that it was manufactured according to the standard. ASME International cannot, however, force any manufacturer, inspector, or installer to follow ASME International standards. Their use is voluntary.

Why are voluntary standards effective? Perhaps the American Society for Testing and Materials (ASTM) said it best in its 1991 annual report. “Standards are a vehicle of communication for producers and users. They serve as a common language, defining quality and establishing safety criteria. Costs are lower if procedures are standardized; training is also simplified. And consumers accept products more readily when they can be judged on intrinsic merit.”

A dramatic example of the value and impact codes and standards have had on our society is provided by ASME International’s Boiler and Pressure Vessel Code. Toward the end of the 19th century, boilers of every description, on land and at sea, were exploding with terrifying regularity for want of reliably tested materials, secure fittings, and proper valves. They would continue to do so into the 20th century. Engineers could take pride in the growing superiority of American technology, but they could not ignore the price of 50,000 dead and 2 million injured by accidents annually.

The mechanical engineers who tackled the problems in 1884 began by seeking reliable methods for testing steam boilers. The need for the establishment of universally accepted construction standards would take many more years and resulted in the first edition of the Boiler and Pressure Vessel Code being published by ASME International in 1915.

### Codes and Standards–Related Accreditation, Certification, and Registration Programs

#### Accreditation

Shortly after the Boiler Code was first published, the need emerged for a recognizable symbol to be affixed to a product constructed in accordance with the standards. ASME International commissioned appropriate seals that are now the internationally acknowledged symbols of the Society. The symbol is stamped onto the product.

But how does a manufacturer obtain permission to use one of the symbols? Through the ASME International **accreditation** process, the manufacturer's quality control process is reviewed by an ASME International team. If the quality control system meets the requirements of the applicable ASME International code or standard and the manufacturer successfully demonstrates implementation of the program, the manufacturer is accredited by ASME International. This means that the manufacturer may certify the product as meeting ASME International standards and may apply the stamp to the product.

The stamp consists of a modified cloverleaf (from the shape of the ASME International logo), with letter(s) in the center. The letter(s) indicate the code or section of the code met by the product upon which it is placed. Boiler and pressure vessel stamps issued are

A	Field Assembly of Power Boilers,
E	Electric Boilers,
H	Heating Boilers, Steel Plate, or Cast-Iron Sectional,
HV	Heating Boiler Safety Valves,
HLW	Lined Potable Water Heaters,
M	Miniature Boilers,
N	Nuclear Components,
NPT	Nuclear Component Partial,
NA	Nuclear Installation/Assembly,
NV	Nuclear Safety Valves,
PP	Pressure Piping,
RP	Reinforced Plastic Pressure Vessels,
S	Power Boilers,
U, U2	Pressure Vessels,
UM	Miniature Pressure Vessels,
UV	Pressure Vessel Safety Valves,
V	Boiler Safety Valves.

ASME International also has accreditation programs for nuclear materials, offshore safety and pollution prevention equipment, fasteners, authorized inspection agencies, organizations that certify elevator inspectors, and reinforced thermoset plastic corrosion-resistant vessels.

### Certification

ASME International has also expanded its scope of activity to cover **certification** of individuals. The first program became available in 1992 and covered the qualification and certification of resource recovery facilities operators. They have since added programs to cover operators of hazardous waste incinerators and medical waste incinerators. Programs to certify an individual's knowledge and ability in the area of geometric dimensioning and tolerancing and operators of fossil fuel-fired plants are under development.

### Registration

**Registration** is similar to accreditation; however, it is the term used more frequently in the international arena, particularly when dealing with the International Organization for Standardization (ISO) 9000 program on quality assurance systems. ASME International's ISO 9000 Registration Program has been accredited by the American National Accreditation Program for Registrars of Quality Systems (ANSI-RAB) and the Dutch Council for Certification (RvC) in the following industrial sectors:

- Primary Metals Industries
- Fabricated Metal Products
- Industrial and Commercial Machinery and Equipment
- Reinforced Thermoset Plastic Tanks and Vessels
- Engineering Services

## How Do I Get Codes and Standards?

### Role of ASME International in Mechanical Engineering Standards

ASME International is a nonprofit educational and technical organization with more than 125,000 members, most of whom are practicing engineers. About 20,000 are students. ASME International has a wide variety of programs: publishing, technical conferences and exhibits, engineering education,

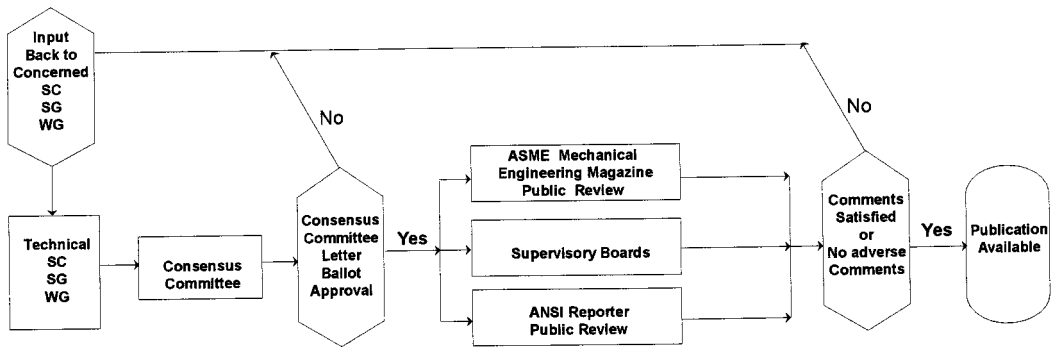

government relations, and public education, as well as the development of codes and standards, all aimed at serving the engineering profession, the public, industry, and government.

The ASME International Board of Governors has delegated the codes and standards activity to a 22-member Council on Codes and Standards, which directs all aspects of the program. Under the Council are ten boards, also made up of ASME International members and other interested persons; supervisory boards in turn oversee committees, each responsible for a specific area of standard development.

Committees in one form or another have dealt with standards since the first test code in 1884. Currently, there are more than 100 main committees dealing with over 500 standards that are under regular review and revision. Once a standard is accepted, it is printed and made available to manufacturers, regulatory agencies, designers — anyone with an interest in that particular subject. Close to 4000 individuals serve on these committees and their subcommittees, subgroups, and working groups.

After a standard has been considered and reconsidered at meetings and through many drafts, it is sent to the main committee, representing all interests, which votes on the standard. But this is not the final step. Before the draft becomes a standard and is published and ready for distribution, it is made available for public comment and must be approved by the appropriate ASME International supervisory board. This process is illustrated graphically in [Figure 20.4.1](#).

**FIGURE 20.4.1** A typical path for standards approval.

ASME International has been a consistent supporter of the policy of prior announcement of meetings, open meeting rooms, [balanced committees](#), public announcements and reviews, appeal mechanisms, and overall procedural [due process](#).

### Role of ANSI in These and Other Related Standards

In 1911, ASME International was one of a number of organizations which recommended the establishment of an organization to help eliminate conflict and duplication in the development of voluntary standards in the U.S. Such an organization was formed in 1918 and is currently known as the American National Standards Institute (ANSI). ANSI is the U.S. member of the ISO and the administrator of the U.S. National Committee of the International Electrotechnical Committee (IEC). ANSI also serves as a bookseller of domestic and international standards.

The intent of obtaining ANSI approval of a standard is to verify that in establishing the standard, the originating organization has followed principles of openness and due process and has achieved a [consensus](#) of those directly affected by the standard.

## What Standards Are Available?

### Listing of Topics Covered by ASME International Standards

Abbreviations	Flanges
Accreditation	Floor Drains
Air Cooled Heat Exchangers	Flue Gas Desulfurization
Air Cylinders & Adapters	Fluid Flow in Pipes
Air Heaters	Fuel Gas Piping
Atmospheric Water Cooling Equipment	Gage Blanks
Automatically Fired Boilers	Gage Blocks
Automotive Lifting Devices	Gas Flow Measurement
Backwater Valves	Gas Transmission and Distribution Piping Systems
Boilers	Gas Turbine Power Plants
Bolts	Gas Turbines
Building Services Piping	Gaseous Fuels
Cableways	Gaskets
Cargo Containers	Gauges
Carriers	Graphic Symbols
Castings and Forgings	Hand Tools
Centrifugal Pumps	High Lift Trucks
Chemical Plant and Petroleum Refinery Equipment	Hoists
Chucks and Chuck Jaws	Hooks
Cleanouts	Hydroelectric Equipment
Coal Pulverizers	Incinerators
Compressors	Indicated Power
Consumable Tools	Industrial Sound
Conveyors	Industrial Trucks and Vehicles
Coordinate Measuring Machines	Internal Combustion Engine Generator Units
Cranes	Ion Exchange Equipment
Deaerators	Jacks
Density Determination	Keys
Derricks	Keyseats
Dial Indicators	Knurling
Diaphragm Seals	Letter Symbols
Dies	Lifts
Diesel and Burner Fuels	Limits and Fits
Digital Systems	Line Conventions and Lettering
Dimensional Metrology	Linear Measurements
Dimensioning and Tolerancing	Liquid Transportation Systems
Drafting	Low Lift Trucks
Drains	Machine Guarding
Dumbwaiters	Machine Tools
Ejectors	Manlifts
Elevators	Material Lifts
Escalators	Measurement
Exhausters	Mechanical Power Transmission Apparatus
Fans	Mechanical Springs
Fasteners	Metric System
Feedwater Heaters	
Fittings	

Milling Machines	Screws
Model Testing	Slings
Monorails	Slip Sheets
Moving Walks	Spray Cooling Systems
Nuclear Facilities and Technology	Stainless Steel Pipe
Nuts	Stands
Offshore Oil and Gas Operations	Steam-Generating Units
Oil Systems	Steel Stacks
Optical Parts	Storage/Retrieval Machines
Pallets	Storage Tanks
Particulate Matter	Surface Texture
Performance Test Codes	Temperature Measurement
Pins	Thermometers
Pipe Dimensions	Tools
Pipe Threads	Transmission Apparatus
Piping	Transmission Chains
Pliers	Turbines
Plumbing	Valves
Pressure Transducers	Washers
Pressure Vessels	Waste Facility Operators
Pumps	Water Hammer Arresters
Quality Assurance	Weighing Scales
Reamers	Welded Aluminum-Alloy Storage Tanks
Refrigeration Piping	Wheel Dollies
Resource Recovery Facility Operators	Wheelchair Lifts
Retaining Rings	Whirlpool Bathtub Appliances
Rivets	Wind Turbines
Safety and Relief Valves	Window Cleaning
Screw Threads	Wrenches

### Where Do I Go if the Subject I Want Is Not on This List?

With the constant creation and revision of standards, not to mention the large number of different SDOs, it is impractical to search for standards-related information in anything other than an electronic format. The latest information on ASME International's codes and standards can be found on the World Wide Web (WWW). ASME International's home page is located at <http://www.asme.org>. It contains a searchable catalog of the various codes and standards available as well as general information about the other areas ASME International is involved with. Additional information on drafts out for public review and committee meeting schedules will be added as the home page continues to evolve.

Another useful Web site is provided by the National Standards System Network (NSSN). This is a project which is still under development, but has the goal of presenting a comprehensive listing of all bibliographic information on standards and standards-related material. Eventually, this site may also provide direct electronic access to the standards themselves. The NSSN page is located at <http://nssn.org>. This site is also useful in that it provides links to many of the SDO's Web sites.

### Defining Terms

**Accreditation:** The process by which the ability of an organization to produce a product according to a specific code or standard is evaluated. It is not an actual certification of a specific product, but does provide a third-party evaluation of the manufacturer's competence to certify that individual products are in compliance with the applicable standards.

**Balanced committee:** A committee in which the consensus body responsible for the development of a standard comprises representatives of all categories of interest that relate to the subject (e.g., manufacturer, user, regulatory, insurance/inspection, employee/union interest). A balanced committee ensures that no one interest group can dominate the actions of the consensus body.

**Certification:** The process by which an individual's training or abilities to perform a task according to a specific code or standard is evaluated.

**Code:** A standard which is, or is intended to be, adopted by governmental bodies as one means of satisfying legislation or regulation.

**Consensus:** This means that substantial agreement has been reached by directly and materially affected interest groups. It signifies the concurrence of more than a simple majority, but not necessarily unanimity. Consensus requires that all views and objections be considered and that an effort be made toward their resolution.

**Due process:** A procedure by which any individual or organization who believes that an action or inaction of a third party causes unreasonable hardship or potential harm is provided the opportunity to have a fair hearing of their concerns.

**Registration:** Similar to accreditation, it is the term used more frequently in the international arena, particularly when dealing with the ISO 9000 program on quality assurance systems.

**Standard:** A set of technical definitions, requirements, and guidelines for the uniform manufacture of items; safety, and/or interchangeability.

## Further Information

*The Engineering Standard, A Most Useful Tool* by Albert L. Batik is a comprehensive work covering the impact of standards in marketing and international trade as well as their application to traditional areas such as design, manufacturing, and construction.

*The Code: An Authorized History of the ASME Boiler and Pressure Vessel Code* by Wilbur Cross provides an in-depth look at events which led to need for codes and the pioneers who created the Boiler and Pressure Vessel Code.

## 20.5 Optics\*

Roland Winston and Walter T. Welford (deceased)

### Geometrical Optics

Geometrical optics is arguably the most classical and traditional of the branches of physical science. By the time Newton wrote his *Principia*, geometrical optics was already a highly developed discipline. Optical design of instruments and devices has been worked out and improved over the centuries. From the telescopes of Galileo to the contemporary camera lens, progress while impressive has been largely evolutionary with modern design benefiting enormously from the availability of fast, relatively inexpensive digital computers. It is noteworthy that even in the last 20 years progress has been made by extending the classical model to problems where image formation is not required, or desired. We shall touch on these developments of “nonimaging optics” later in this section. But first we treat classical geometrical optics. In this model, a “point source” emits rays which are straight lines in a vacuum or in a homogeneous isotropic dielectric medium. Light travels at different speeds in different dielectrics. Its speed is given by  $c/n$ , where  $c$  is the speed in vacuum ( $299,792,458 \text{ m sec}^{-1}$ ) and  $n$ , the *refractive index*, depends on the medium and on the frequency of the light.

A ray is refracted at an interface between two media. If  $\mathbf{r}$  and  $\mathbf{r}'$  are unit vectors along the incident and refracted directions,  $n$  and  $n'$  are the respective refractive indexes, and  $\mathbf{n}$  is the unit normal to the interface, then the ray directions are related by

$$n\mathbf{n} \times \mathbf{r} = n'\mathbf{n} \times \mathbf{r}' \quad (20.5.1)$$

which is the law of refraction, *Snell's law*, in vector form. More conventionally, Snell's law can be written

$$n \sin I = n' \sin I' \quad (20.5.2)$$

where  $I$  and  $I'$  are the two angles formed where the normal meets the interface, the angles of incidence and refraction. The two rays and the normal must be coplanar. Figure 20.5.1 illustrates these relationships and shows a reflected ray vector  $\mathbf{r}''$ . Equation (20.5.1) can include this by means of the convention that after a reflection we set  $n'$  equal to  $-n$  so that, for reflection,

$$\mathbf{n} \times \mathbf{r} = -\mathbf{n} \times \mathbf{r}'' \quad (20.5.3)$$

FIGURE 20.5.1

With a bundle or pencil of rays originating in a point source and traversing several different media, e.g., a system of lenses, we can measure along each ray the distance light would have traveled in a given time  $t$ ; these points delineate a surface called a *geometrical wavefront*, or simply a *wavefront*. Wavefronts are surfaces orthogonal to rays (the Malus–Dupin theorem). (It must be stressed that wavefronts are a

\*From Welford, W.T., *Useful Optics*, reproduced with permission of University of Chicago Press.

concept of geometrical optics and that they are *not* surfaces of constant phase, phase fronts, of the light waves in the scalar or electromagnetic wave approximations. However, in many situations the geometrical Earth are a very good approximation of phase fronts.) Thus, if successive segments of a ray are of length  $d_1, d_2, \dots$ , a wave front is a locus of constant  $\sum nd$  or, passing to the limit,  $\int n dl$ . This quantity is called an *optical path length*. (See [Figure 20.5.2](#).)

**FIGURE 20.5.2**

Optical path lengths enter into an alternative to Snell’s law as a basis for geometrical optics. Consider any path through a succession of media from, say,  $P$  to  $P'$ . We can calculate the optical path length  $W$  from  $P$  to  $P'$ , and it will depend on the shape of this path, as shown in [Figure 20.5.3](#). Then *Fermat’s principle* states that, if we have chosen a physically possible ray path, the optical path length along it will be stationary (in the sense of the calculus of variations) with respect to small changes of the path. (The principle as originally formulated by Fermat proposed a *minimum* time of travel of the light. Stationarity is strictly correct, and it means roughly that, for any small transverse displacement  $\delta x$  of a point on the path, the change in optical path length is of order  $\delta x^2$ .) For our purposes, Fermat’s principle and Snell’s law are almost equivalent, but in the case of media of continuously varying refractive index it is sometimes necessary to invoke Fermat’s principle to establish the ray path. Apart from such cases, either one can be derived from the other.

**FIGURE 20.5.3**

Either Fermat or Snell can be used to develop the whole edifice of geometrical optics in designing optical systems to form images.

**Symmetrical Optical Systems**

The axially symmetric optical system, consisting of lenses and/or mirrors with revolution symmetry arranged on a common axis of symmetry, is used to form images. Its global properties are described in terms of *paraxial* or *Gaussian* optics. In this approximation only rays making small angles with the axis of symmetry and at small distances from the axis are considered. In Gaussian optics, we know from symmetry that rays from any point on the axis on one side of the system emerge on the other side and meet at another point on the axis, the *image point*. This leads to the well-known formalism of principal planes and focal planes shown in [Figure 20.5.4](#). A ray entering parallel to the axis passes through  $F'$ , the second, or image-side, principal focus on emerging from the system, and a ray entering through  $F$ , the first principal focus, emerges parallel to the axis. A ray incident on the first, or object-side, principal plane  $P$  at any height  $h$  emerges from the image-side principal plane  $P'$  at the same height  $h$  so that the principal planes are *conjugated* planes of unit magnification. Excluding for the moment the special case

FIGURE 20.5.4

FIGURE 20.5.5

in which a ray entering parallel to the axis also emerges parallel to the axis, these four points yield a useful graphical construction for objects and images, as depicted in Figure 20.5.5.

The two focal lengths  $f$  and  $f'$  are defined as

$$f = PF, \quad \square \quad f' = P'F' \tag{20.5.4}$$

Their signs are taken according to the usual conventions of coordinate geometry, so that in Figure 20.5.4  $f$  is negative and  $f'$  is positive. The two focal lengths are related by

$$n'/f' \equiv -n/f \tag{20.5.5}$$

where  $n$  and  $n'$  are the refractive indexes of the object and image spaces, respectively.

Conjugated distances measured from the principal planes are denoted by  $l$  and  $l'$ , and the conjugate distance equation relating object and image positions is

$$n'/l' - n/l = n'/f' \equiv -n/f \tag{20.5.6}$$

The quantity on the right — that is, the quantity on either side of Equation (20.5.5) — is called the *power* of the system, and is denoted by  $K$ .

Another form of the conjugate distance equation relates distances from the respective principal foci,  $z$  and  $z'$ .

$$zz' \equiv ff' \tag{20.5.7}$$

This equation yields expressions for the transverse magnification:

$$\eta'/\eta = -f/z \equiv -z'/f' \tag{20.5.8}$$

This is useful to indicate paraxial rays from an axial object point  $O$  to the corresponding image point  $O'$  as in Figure 20.5.6 with convergence angles  $u$  and  $u'$  positive and negative, respectively, as drawn in the figure. (Paraxial angles are small but diagrams like Figure 20.5.6 can be drawn with an enlarged transverse scale. That is, convergence angles and intersection heights such as  $h$  can all be scaled up by the same factor without affecting the validity of paraxial calculations.) Then, if  $\eta$  and  $\eta'$  are corresponding object and image sizes at these conjugates, the following relation exists between them:

FIGURE 20.5.6

$$n\eta u = n'\eta' u' \tag{20.5.9}$$

In fact, for a given paraxial ray starting from  $O$ , this quantity is the same at any intermediate space in the optical system. That is, it is an invariant, called the Lagrange invariant. It has the important property that its square is a measure of the light flux collected by the system from an object of size  $\eta$  in a cone of convergence angle  $u$ .

The above discussion covers all general Gaussian optic properties of symmetrical optical systems. We next look at particular systems in detail. To do this, we abandon the skeleton representation of the system by its principal planes and foci and consider it as made up of individual refracting or reflecting surfaces.

Figures 20.5.7 and 20.5.8 show the basic properties of a single spherical refracting surface of radius of curvature  $r$  and of a spherical mirror. In each case  $r$  as drawn is positive. These diagrams suggest that the properties of more complex systems consisting of more than one surface can be found by tracing paraxial rays rather than by finding the principal planes and foci, and this is what is done in practice. Figure 20.5.9 shows this with an iterative scheme outlined in terms of the convergence angles. The results can then be used to calculate the positions of the principal planes and foci and as the basis of aberration calculations. For details see Welford (1986). The actual convergence angles which can be admitted, as distinguished from notional paraxial angles, are determined either by the rims of individual components or by stops deliberately inserted at places along the axis chosen on the basis of aberration theory. Figure 20.5.10 shows an *aperture stop* in an intermediate space of a system. The components of the system to the left of the stop from an image (generally virtual) which is “seen” from the object position (this image is usually virtual, i.e., it is not physically accessible to be caught on a ground-glass screen like the image in an ordinary looking glass); this image is called the *entrance pupil*, and it limits the angle of beams that can be taken in from the object. Similarly, on the image side there is an *exit pupil*, the image of the stop by the components to the right, again usually virtual. This pupil may also determine the angles of beams from off-axis object point  $O$  and  $O'$ ; the central ray of the beam from  $O$  passes through the center of the entrance pupil (and therefore through the center of the aperture stop and the center of the exit pupil) and it is usually called the *principal, chief, or reference ray* from this object point. The rest of the beam or pencil from  $O$  may be bounded by the rim of the entrance pupil, or it may happen that part of it is *vignetted* by the rim of one of the components.

Although the aperture stop is usually thought of as being inside an optical system, as in a photographic objective, it is sometimes placed outside, and one example is the *telecentric stop* shown in Figure 20.5.11. The stop is at the object-side principal focus, with the result that in the image space all the principal rays emerge parallel to the optical axis. A telecentric stop can be at either the object-side or the image-side principal focus, and the image conjugates can be anywhere along the axis. The effect is that the pupil on the opposite side of the telecentric stop is at infinity, a useful arrangement for many purposes. It may happen that the telecentric stop is between some of the components of the system.

The above information is all that is needed to determine how a given symmetrical optical system behaves in Gaussian approximation for any chosen object plane. Suitable groups of rays can be used to set out the system for mechanical mounting, clearances, etc.; however, it is often easier and adequate in terms of performance to work with the *thin-lens model* of Gaussian optics. This model uses complete

$$\frac{n'}{l'} - \frac{n}{l} = \frac{n' - n}{r} = K$$

$$n'u' - nu = -hK$$

FIGURE 20.5.7

$$\frac{1}{l'} + \frac{1}{l} = \frac{2}{r} = -K$$

$$u' + u = hK$$

FIGURE 20.5.8

$$n'u' - nu = -hK$$

$$u_{,1} = u'$$

$$h_{,1} = h + d'u'$$

$$n'_{,1}u'_{,1} - n_{,1}u_{,1} = -h_{,1}K_{,1}$$

FIGURE 20.5.9

FIGURE 20.5.10

FIGURE 20.5.11

FIGURE 20.5.12

lenses of negligible thickness instead of individual surfaces. Figure 20.5.12 shows the properties of a thin lens. A system of thin lenses can be ray traced to find its properties, locate foci and ray clearances, etc., and very often the results will be good enough to use without further refinement. This is particularly true of systems involving unexpanded laser beams, where the beam diameters are quite small.

We omitted from our discussion of Figure 20.5.4 the special case in which a ray incident parallel to the optical axis emerges parallel to the axis, as in Figure 20.5.13. This is an *afocal* or *telescopic* system; it forms an image at infinity of an object at infinity, and the angular magnification is given by the ratio of the ray incidence heights. An afocal system also forms images of objects at finite distances, as indicated by the rays drawn in the figure. The transverse magnification is then constant for all pairs of conjugates.

**Plane Mirrors and Prisms**

A single-plane mirror used to deflect or rotate an optical axis needs no explanation, but some useful points can be made about combinations of mirrors. Two mirrors at an angle  $\theta$  turn the beam through  $2\theta$  about the line of intersection of the mirror planes, whatever the angle of incidence on the first mirror, as in Figure 20.5.14. The diagram is drawn for a ray in the plane perpendicular to the line of intersection

FIGURE 20.5.13

FIGURE 20.5.14

FIGURE 20.5.15

FIGURE 20.5.16

of the mirror planes, but it is equally valid if the ray is not in this plane, i.e., the diagram is a true projection. In particular, if the mirrors are at right angles, as in [Figure 20.5.15](#), the direction of the ray is reversed in the plane of the diagram. Three plane mirrors at right angles to each other, forming a corner of a cube as in [Figure 20.5.16](#), reverse the direction of a ray incident in *any* direction if the ray meets all three mirrors in any order.

These properties are more often used in prisms in the corresponding geometry. Total internal reflection, as in, for example, the right-angle prism ([Figure 20.5.17](#)), is a great advantage in using prisms for turning beams. The condition for total internal reflection is

$$\sin I > 1/n \tag{20.5.10}$$

FIGURE 20.5.17

The *critical angle* given by  $\sin I = 1/n$  is less than  $45^\circ$  for all optical glasses, and probably for all transparent solids in the visible spectrum. Total internal reflection is 100% efficient provided the reflecting surface is clean and free from defects, whereas it is difficult to get a metallized mirror surface that is better than about 92% efficient. Thus, with good anti-reflection coating on the input and output surfaces a prism, such as that shown in Figure 20.5.17, transmits more light than a mirror.

Roof prisms and cube-corner prisms, the analogs of Figure 20.5.15 and 20.5.16, have many uses. The angle tolerances for the right angles can be very tight. For example, roof edges form part of the reversing prism system in some modern binoculars, and an error  $\epsilon$  in the right angle causes an image doubling in angle of  $4n\epsilon$ . The two images are those formed by the portions of the beam incident at either of the two surfaces, which should have been at exactly  $90^\circ$ .

In addition to turning the axis of a system, mirror and prism assemblies sometimes rotate the image in unexpected ways. The effect can be anticipated by tracing, say, three rays from a notional object such as the letter F (i.e., an object with no symmetry). A more direct and graphic method is to use a strip of card and mark arrows on each end as in Figure 20.5.18a. The card is then folded without distorting it as in Figure 20.5.18b to represent, say, reflection at the hypotenuse of the right-angle prism, and the arrows show the image rotation. The process is repeated in the other section, as in Figure 20.5.18c. Provided the folding is done carefully, without distortion, this procedure gives all image rotations accurately for any number of successive reflections.

FIGURE 20.5.18

The Dove prism (Figure 20.5.19) is an example of an image-rotating prism. When the prism is turned through an angle  $\phi$  about the direction of the incident light, the image turns in the same direction through  $2\phi$ . A more elaborate prism with the same function is shown in Figure 20.5.20. The air gap indicated between the hypotenuses of the two component parts needs to be only about  $10\ \mu\text{m}$  or so thick to ensure total internal reflection. Any prism or mirror assembly like this with an odd number of reflections will serve as an image rotator. Figure 20.5.20 illustrates an elegant advantage of prisms over mirrors; the system can be made compact by using the same optical surface both for reflection and for transmission.

FIGURE 20.5.19

FIGURE 20.5.20

FIGURE 20.5.21

Figure 20.5.21 shows a typical beam-splitting (or combining) prism, a component of many diverse optical systems. The beam-splitting surface may be approximately neutral, in which case it would be a thin metal layer, or it may be dichroic (reflecting part of the spectrum and transmitting the rest), or it may be polarizing (transmitting the p-polarization and reflecting the s-polarization of a certain wavelength range). In the last two cases the reflecting-transmitting surface is a dielectric multilayer and its performance is fairly sensitive to the angle of incidence.

Prisms as devices for producing a spectrum have been largely replaced by diffraction grating (See Figure 20.5.22). The latter have several advantages for direct spectroscopy, but here are a few specialized areas where prisms are better. Losses in grating through diffraction to unwanted orders are a nuisance in certain astronomical applications where every photon counts. Another example of an area where prisms are preferable is wavelength selection in multiwavelength lasers: a prism inside the laser resonator with adequate angular dispersion ensures that only one wavelength will be produced, and one scans through the available wavelengths by rotating the prisms at and away from the position of minimum deviation. The significance of the minimum deviation position is that the effects of vibrations and placement errors are least. Also, if the shape of the prism is isosceles, the resolving power will be a maximum at minimum deviation. The main formulas relating to dispersing prisms are as follows.

Spectroscopic resolving power:

FIGURE 20.5.22

$$\lambda/\Delta\lambda = (t_1 - t_2) \, dn/d\lambda \tag{20.5.11}$$

where  $t_1 - t_2$  is the difference between the path lengths in glass from one side of the beam to the other.

Angular dispersion:

$$dI_2'/d\lambda = \sin A (dn/d\lambda) / (\cos I_1' \cos I_2') \tag{20.5.12}$$

$$= 2 \sin(A/2) (dn/d\lambda) / \cos I_2 \tag{20.5.13}$$

at minimum deviation.

Spectrum line curvature:

$$1/\text{radius} = \left[ (n^2 - 1) / nf \right] \sin A / (\cos I_1' \cos I_2') \tag{20.5.14}$$

$$= \left[ (n^2 - 1) / n^2 f \right] 2 \tan I_1 \tag{20.5.15}$$

at minimum deviation, where  $f$  is the focal length of the lens which brings the spectrum to a focus.

The spectrum line curvature refers to the observation that the image of the entrance slit of the spectroscopy produced by placing a lens after the prism is actually parabolic. The parabola is convex toward the longer wavelengths. The reason the image is curved is that rays out of the principal plane of the prism are deviated more than rays in the plane, a straightforward consequence of the application of Snell's law. For rays with angle out of the plane the extra deviation can be parametrized by an additional contribution to the index of refraction given by

$$dn \approx \epsilon^2 (n^2 - 1) (2n) \tag{20.5.16}$$

If the length of the slit image is  $L$ , then  $\epsilon \approx L/(2f)$ , where  $f$  is the focal length of the lens. Moreover, from Equation (20.5.12) we have

$$dI_2'/dn = \sin A / (\cos I_1' \cos I_2') \tag{20.5.17}$$

$$= (2/n) \tan I_1 \tag{20.5.18}$$

at minimum deviation. The curvature of the slit image readily follows from these relations.

FIGURE 20.5.23

FIGURE 20.5.24

The typical dispersing prism of constant deviation shown in [Figure 20.5.23](#) has the property that, if it is placed in a collimated beam, the wavelength which emerges at right angles to the incident beam is always at minimum deviation so that the spectrum is scanned by rotating the prism about a suitable axis such as the one indicated.

A prism used a long way from minimum deviation will expand or contract a collimated beam in one dimension. [Figure 20.5.24](#) shows a pair of prisms used in this way to turn a laser beam of elliptical profile (from a diode laser) into a beam of circular profile by expanding it in the plane of the diagram only.

## Nonimaging Optics

In one important respect conventional *image-forming* optical design is quite inefficient, that is, in merely concentrating and collecting light. This is well illustrated by an example taken from solar energy concentration ([Figure 20.5.25](#)). The flux at the surface of the sun ( $\approx 63 \text{ W/mm}^2$ ) falls off inversely with the square of the distance to a value  $\approx 1.37 \text{ mW/mm}^2$  above the Earth's atmosphere or typically 0.8 to 1  $\text{mW/mm}^2$  on the ground. The second law of thermodynamics permits an optical device (*in principle*) to concentrate the dilute solar flux at Earth so as to attain temperatures up to but not exceeding that of the sun's surface. This places an upper limit on the solar flux density achievable on Earth and correspondingly on the concentration ratio of any optical device. From simple geometry, this limiting concentration ratio is related to the sun's angular size ( $2\theta$ ) by  $C_{\text{max}} = 1/\sin^2\theta \approx 1/\theta^2$  (small angle approximation). We will call this thermodynamic limit the *sine law of concentration*. Therefore, since  $\theta = 0.27^\circ$  or 4.67 mrad,  $C_{\text{max}} \approx 46,000$ . When the target is immersed in a medium of refractive index  $n$ , this limit is increased by a factor  $n^2$ ,  $C_{\text{max}} = n^2/\sin^2\theta$ . This means that a concentration of about 100,000 will be the upper limit for ordinary ( $n \approx 1.5$ ) refractive materials. In experiments at the University of Chicago we actually achieved a solar concentration of 84,000 by using a nonimaging design with a refractive medium (sapphire). We would not even have come close using conventional designs, not for any fundamental reason but because imaging optical design is quite inefficient for delivering maximum concentration. For example, consider the paraboloidal mirror of a telescope used to concentrate sunlight at its focus ([Figure 20.5.26](#)). We can relate the concentration ratio to the angle  $2\phi$  subtended by the paraboloid at

**$1/\sin^2\theta$  Law of Maximum Concentration**

Earth:Sun Example

$I_2 = (r_1/r_2)^2 I_1$  Inverse Square Fall-off of Flux (Gauss's Law)

$\sin(\theta) = r_1/r_2 \longrightarrow I_1/I_2 = 1/\sin^2\theta$

$C I_2 \leq I_1$  (2nd Law of Thermodynamics)

Maximum Concentration  $C = 1/\sin^2\theta = 46,000$

FIGURE 20.5.25

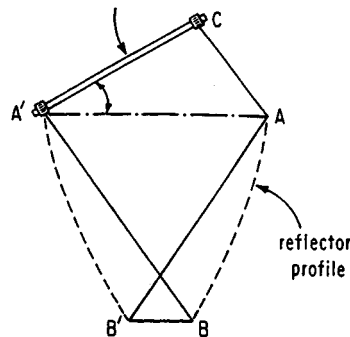

FIGURE 20.5.26

its focus and the sun's angular size ( $2\theta_s$ ),  $C = (\sin \phi \cos \phi / \theta_s)^2 = (1/4) \sin^2 2\phi / \theta_s^2$ , where we have used the small angle approximation for  $\theta_s$ . Notice that  $C$  is maximized at  $\phi = \pi/4$ , or  $C = 1/(4\theta_s^2) = (1/4) C_{max}$ . In fact, this result does not depend on the detailed shape of the paraboloid and would hold for any focusing mirror. One fares no better (and probably worse) with a lens (a refracting telescope), since the optimum paraboloid in the above example is equivalent in concentrating performance to a lens with focal ratio  $f = 1$  which has been corrected for spherical aberration and coma. Such high-aperture lenses are typically complex structures with many components. The thermodynamic limit would require a lens with focal ratio  $f = 0.5$  which, as every optical designer knows, is unattainable. The reason for this large shortfall is not hard to find. The paraboloid images perfectly on-axis, but has severe off-axis aberration (coma) which produces substantial image blurring and broadening. Nonimaging optics began in the mid 1960s with the discovery that optical systems could be designed and built that approached the theoretical limit of light collection (the sine law of concentration). The essential point is that requiring an image is unnecessarily restrictive when only concentration is desired. Recognition of this restriction and relaxation of the associated constraints led to the development of nonimaging optics. A nonimaging concentrator is essentially a “funnel” for light. Nonimaging optics departs from the methods of traditional optical design to develop instead techniques for maximizing the collecting power of concentrating elements and systems. Nonimaging designs exceed the concentration attainable with focusing techniques by factors of four or more and approach the theoretical limit (ideal concentrators). The key is simply to dispense with image-forming requirements in applications where no image is required.

Since its inception, the field has undergone three periods of rapid conceptual development. In the 1970s the “string” (see Figures 20.5.27 and 20.5.28) or “edge-ray” method (see Welford and Winston, 1989) was formulated and elaborated for a large variety of geometries. This development was driven by the desire to design wide-angle solar concentrators. It may be succinctly characterized as  $\int n \, dl = \text{constant}$  along a string. (Notice that replacing “string” by “ray,” Fermat’s principle, gives all of imaging optics.) In the early 1980s, a second class of algorithms was found, driven by the desire to obtain ideally perfect solutions in three dimensions (3D) (The “string” solutions are ideal only in 2D, and as figures of revolution in 3D are only approximately ideal, though still very useful.) This places reflectors along the lines of flow of a radiation field set up by a radiating lambertian source. In cases of high symmetry such as a sphere or disk, one obtains ideal solutions in *both* 2D and 3D. The third period of rapid development has taken place only in the past several years; its implications and consequences are still in the process of being worked out. This was driven by the desire to address a wider class of problems in illumination that could not be solved by the old methods, for example, uniformly illuminating a plane (e.g., a table or a wall) by a lambertian light source (e.g., a fluorescent light). It is well known that the far-field illuminance from a lambertian source falls off with a power of the cosine of the radiating angle  $\theta$ . For example, cylindrical radiators (such as a fluorescent lamp) produce a  $\cos^2\theta$  illuminance on a distant plane, strip radiators produce a  $\cos^3\theta$  illuminance, while circular disk radiators produce a  $\cos^4\theta$  illuminance. But suppose one desires a predetermined far-field illuminance pattern, e.g., uniform illuminance? The old designs will not suffice; they simply transform a lambertian source radiating over  $2\pi$  into a lambertian source radiating over a restricted set of angles. The limitation of the old designs is that they are too static and depend on a few parameters, such as the area of the beam  $A_1$  and the divergence angle  $\theta$ . One needs to introduce additional degrees of freedom into the nonimaging designs to solve a wider class of problems.

$$\int_w^{B'} n \, dl = \text{Constant. } AC + AB' = A'B + BB'$$

$$AC = AA' \sin \theta$$

$$AB' = A'B$$

$$\Rightarrow AA' \sin \theta = BB'$$

FIGURE 20.5.27

### Edge-Ray Optics

One way to design nonimaging concentrators is to reflect the extreme input rays into the extreme output rays. We call this the “edge-ray method.” An intuitive realization of this method is to wrap a string about both the light source and the light receiver, then allow the string to unwrap from the source and wrap around the receiver. In introducing the string picture, we follow an insight of Hoyt Hottel (Massachusetts Institute of Technology), who discovered many years ago that the use of strings tremendously simplified the calculation of radiative energy transfer between surfaces in a furnace. Our string is actually a “smart”

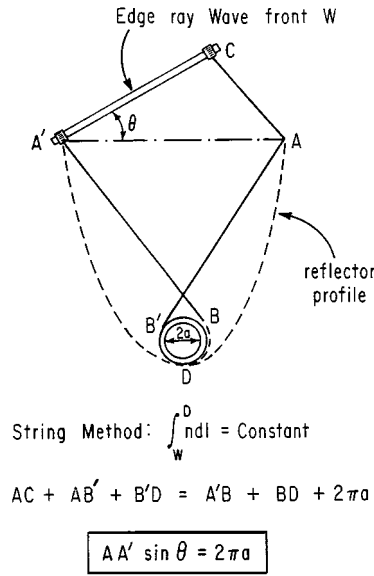

FIGURE 20.5.28

string; it measures the optical path length (ordinary length times the index of refraction) and refracts in accordance with Snell's law at the interface between different refracting materials.  $\int n dl = \text{constant}$ . The locus traced out turns out to be the correct reflecting surface! Let's see how this works in the simplest kind of problem nonimaging optics addresses: collecting light over an entrance aperture  $AA'$  with angular divergence  $\pm\theta$  and concentrating the light onto an exit aperture  $BB'$  (Figure 20.5.27). We attach one end of the string to the edge of the exit aperture  $B$  and the loop at the other end over a line  $WW'$  inclined at angle  $\theta$  to the entrance aperture (this is the same as attaching to a "point at infinity"). We now unwrap the string and trace out the locus of the reflector taking care that string is taut and perpendicular to  $WW'$ . Then we trace the locus of the other side of the reflector. We can see with a little algebra that when we are done the condition for maximum concentration has been met. When we start unwrapping the string, the length is  $AB' + BB'$ ; when we finish, the same length is  $WA' + A'B$ . But  $WA' = AA' \sin \theta$ , while  $AB' = A'B$ . So we have achieved  $AA'/BB' = 1/\sin \theta$  which is maximum concentration! To see why this works, we notice that the reflector directs all rays at  $\pm\theta$  to the edges  $BB'$  so that rays at angles  $> \pm\theta$  are reflected out of the system and rejected. Now there is a conservation theorem for light rays called conservation of phase space or "etendue" which implies that if the rays at angles  $> \pm\theta$  are rejected, then the rays that have angles  $< \theta$  are all collected. Next we can try a more-challenging problem, where the "exit aperture" is a cylinder of radius  $a$  (Figure 20.5.28). Now we attach the string to a point on the cylinder and wrap it around the cylinder. When the string is unwrapped, we find that  $AA'/2\pi a = 1/\sin \theta$  which is maximum concentration on the surface of the cylinder! Such designs are useful for solar-thermal concentrators since the typical receiver is a tube for carrying fluid. A solar plant for powering air conditioners that uses this design is shown in Figure 20.5.29. As already mentioned, there is an alternative method for designing "ideal" optical systems which bears little resemblance to the "string method" already described. We picture the aggregate of light rays traversing an optical system as a fluid flow in an abstract space called phase space. This is the "space" of ray positions and ray directions multiplied by the index of refraction, so it has twice the number of dimensions of ordinary space. By placing reflectors along the lines of flow of this vector field, nonimaging designs are generated. Flow-line designs are perfect in three dimensions, while the string designs rotated about an axis are not. On the other hand, the number of flow-line designs are much more restricted. For details see Welford and Winston (1989).

**FIGURE 20.5.29**

## Lasers

Lasers are by now a ubiquitous light source with certain properties in addition to coherence and monochromaticity which have to be taken account of in some applications. Aside from many research applications of lasers, the HeNe laser at 632.8 nm wavelength has been available for several decades for alignment, surveying, and the like. But the explosive uses of lasers have come only recently with the advent of the solid-state diode laser. To appreciate the convenience of diode lasers one can draw upon the analogy between transistors and vacuum tubes. Inexpensive diode lasers are in widespread use in compact disk players, optical disk readers, and fiber-optics communications. The list of consumer applications is growing rapidly (e.g., laser pointers). In addition, diode lasers are used in arrays to optically drive (pump) more powerful lasers. The radiation that lasers emit can be highly coherent, and, except for the wavelength, of the same general character as the radiation from a radio frequency oscillator. We can identify four elements common to nearly all lasers (we follow the discussion in Mandel and Wolf, 1995, which should be consulted for details):

1. An optical resonator, generally formed by two or more mirrors;
2. A gain medium in which an inverted atomic population between the laser energy levels is established;
3. An optical pump or energy source to excite the gain medium;
4. A loss mechanism by which energy is dissipated or dispersed.

Figure 20.5.30 shows a typical form of laser, in which the resonator is a Fabry–Perot interferometer, and the amplifier is a gas plasma tube wherein a discharge is maintained. To reduce reflection losses from the plasma tube, its end windows are generally arranged at the Brewster angle for linearly polarized light at the laser frequency. The end mirrors are usually provided with multilayer dielectric coatings to make them highly reflecting. Of course, the output mirror needs to have its reflectivity,  $R$ , less than

100%, so that  $(1 - R)$  is commonly the main source of the energy loss that has to be compensated by the gain medium. The cavity mirrors play the important role of feeding photons belonging to the laser modes back into the laser cavity. Most of the spontaneously emitted photons traveling in various other directions are lost. However, photons associated with a cavity resonance mode interact repeatedly with the atoms of the gain medium, and their number grows through stimulated emission, as illustrated in Figure 20.5.31. Once one mode is sufficiently populated, the probability for stimulated emission into that mode exceeds the spontaneous emission probability. In general, when the rate at which photons are fed into the optical cavity mode exceeds the rate at which they are lost from the cavity by the loss mechanism, the amplitude of the laser field starts to grow until a steady state is reached. At that point the rate of radiation by the laser equals the net rate at which energy is supplied. It is easy to see that this is achievable by an inverted population between the two atomic laser levels, with more atoms in the upper laser state than in the lower. If  $N_2, N_1$  are the upper state and lower state populations, the rate of absorption of laser photons by the atomic system is proportional to  $N_1$ , and the rate of stimulated emission of laser photons by the system is proportional to  $N_2$ , with the same constant of proportionality for both. If  $N_2$  exceeds  $N_1$  sufficiently, all the radiation losses can be made good by the atomic system. It can be shown that the condition for laser action (in a single mode) is

FIGURE 20.5.30 A simple form of laser.

FIGURE 20.5.31 Illustration of the growth of the stimulated emission probability with the intensity of the mode.

$$N_2 - N_1 > 2A(1 - R)/\lambda^2 \tag{20.5.19}$$

where  $A$  is the cross-sectional area of the laser and  $\lambda$  is the wavelength.

We next summarize how the special properties of laser beams are to be taken into account in optical design. The well-known Gaussian intensity profile of laser beams persists if it is taken through a sequence of lenses along the axis, and at certain points that can be more-or-less predicted by paraxial optics a “focus” is formed. But when, as often happens, the convergence angle in the space in which this occurs is small, say, 1 mrad or less, some departures from the predictions of the paraxial optics occur. We shall examine these effects, since they are of importance in many of the systems already mentioned.

### Gaussian Beams

In paraxial approximation the simplest form of a single-mode beam is the TEM<sub>00</sub> Gaussian beam shown in Figure 20.5.32. Starting from the narrowest part, known as the waist, the beam diverges with spherical phase fronts. The complex amplitude at the waist has the form

$$A = A_0 \exp\left(-r^2/\omega_0^2\right) \tag{20.5.20}$$

where  $\omega_0$  is called the beam width and  $r$  is a radial coordinate.

FIGURE 20.5.32

At a distance  $z$  along the beam in either direction, the complex amplitude is, apart from a phase factor,

$$A = (\omega_0/\omega)A_0 \exp(-r^2/\omega^2) \quad (20.5.21)$$

where  $\omega$  is given by

$$\omega(z) = \omega_0 \left[ 1 + (\lambda z / \pi \omega_0^2) \right]^{1/2} \quad (20.5.22)$$

At a distance  $z$  from the waist, the phase fronts have a radius of curvature  $R$  given by

$$R(z) = z \left[ 1 + (\pi \omega_0^2 / \lambda z)^2 \right] \quad (20.5.23)$$

The beam contour of constant intensity  $A_0^2/e^2$  is a hyperboloidal surface of (small) asymptotic angle given by

$$\theta = \lambda / \pi \omega_0 \quad (20.5.24)$$

It can be seen that the centers of curvature of the phase fronts are not at the beam waist; in fact the phase front is plane at that point. The geometrical wavefronts are not exactly the same as true phase fronts, and if in this case we postulate that geometrical wavefronts should have their centers of curvature at the beam waist, we have an example of this. However, the difference is small unless the convergence angle is very small or, more precisely, when the Fresnel number of the beam is not much larger than unity:

$$\text{Fresnel number} = \omega^2 / \lambda R \quad (20.5.25)$$

There is nothing special about Gaussian beams to cause this discrepancy between phase fronts and geometrical wavefronts; a similar phenomenon occurs with beams which are sharply truncated by the pupil ("hard-edged" beams). But it happens that it is less usual to be concerned with the region near the focus of a hard-edged beam of small Fresnel number, whereas Gaussian beams are frequently used in this way. Thus, Born and Wolf, *Principles of Optics* (1959) show that the phase front at the focus of a hard-edged beam is also plane, but with rapid changes of intensity and phase jumps across the zeros of intensity.

### Tracing Gaussian Beams

If the beam is in a space of large convergence angle, say, greater than 10 mrad, it can be traced by ordinary paraxial optics, i.e., using the assumption that for all practical purposes the phase fronts are the same as geometrical wavefronts. In a space of small convergence angle it is necessary to propagate the beam between refracting surfaces by means of the proper Gaussian beam formulas and then use paraxial optics to refract (or reflect) the phase front through each surface in turn. To do this, we need

two more formulas to give the position,  $z$ , and size of the beam waist starting from the beam size and phase front curvature at an arbitrary position on the axis, i.e., given  $\omega$  and  $R$ . These are

$$z = R \left[ 1 - \left( \frac{\lambda z}{\pi \omega^2} \right)^2 \right]^{-1/2} \tag{20.5.26}$$

and

$$\omega_0 = \omega \left[ 1 + \left( \frac{\pi \omega^2}{\lambda R} \right)^2 \right]^{-1/2} \tag{20.5.27}$$

Equations (20.5.22) to (20.5.27) enable a Gaussian beam to be traced through a sequence of refracting surfaces as an iterative process. Thus, starting from a beam waist of given size  $\omega_0$  (and angle given by Equation (20.5.24)), we move a distance  $z$  to the first refracting surface. At this surface the beam size  $\omega$  is given by Equation (20.5.22) and the radius of curvature  $R$  of the phase front is given by Equation (20.5.23). The radius of curvature  $R'$  of the refracted phase front is obtained by paraxial optics using the equation of Figure 20.5.7 and taking  $R$  and  $R'$  as the conjugate distances  $l$  and  $l'$ . Then the position and size of the new beam waist are found from Equations (20.5.26) and (20.5.27). These procedures can be carried through all the refracting surfaces of the optical system.

It can be seen from Equation (20.5.26) that  $z$  and  $R$  are substantially equal when  $\lambda R / \pi \omega^2$  is very small. When this is so, there is no need to use these special equations for transferring between surfaces; the iterative equations in Figure 20.5.9 can be used, with the understanding that the paraxial convergence angle  $u$  is the equivalent of the asymptotic angle  $\theta$  in Equation (20.5.24).

There are no simple equations for hard-edged beams corresponding to Equations (20.5.23) to (20.5.27) for use with very small convergence angles. Numerical calculations of the beam patterns near focus have been published for some special cases, and these show, as might be expected, very complex structures near the “focal” region; however, that is defined.

### Truncation of Gaussian Beams

The theoretical origin of the Gaussian beam is as a paraxial solution of the Helmholtz equation, i.e., a solution concentrated near one straight line, the axis, but although most of the power is within the region near the axis the solution is nonzero, although very small, at an infinite distance from the axis. Thus, the Gaussian profile is truncated when it passes through any aperture of finite diameter — e.g., a lens mount, an aperture stop, or even the finite-diameter end mirror of a laser resonator — after which it is no longer Gaussian and the above equations are no longer valid! In practice, this need not be a problem, for if the radius of the aperture is  $2\omega$ , the complex amplitude is down to 1.8% of its value at the center and the intensity is 0.03% of its value at the center. Thus, it is often assumed that an aperture of radius  $2\omega$  has no significant effect on the Gaussian beam, and this assumption is adequate for many purposes, although not all.

Sometimes it is useful to truncate a Gaussian beam deliberately, i.e., turn it into a hard-edged beam, by using an aperture of radius less than, say,  $\omega$ . In this way an approximation to the Airy pattern is produced at the focus instead of a Gaussian profile waist, and this pattern may be better for certain purposes, e.g., for printers where the spot must be as small as possible for an optical system of given numerical aperture.

### Gaussian Beams and Aberrations

In principle, a Gaussian beam is a paraxial beam, from the nature of the approximations made in solving the Helmholtz equation. However, Gaussian beams can be expanded to large diameters simply by letting them propagate a large distance, and they can acquire aberrations by passing through an aberrating lens or mirror system. The beam is then no longer Gaussian, of course, in the strict sense, but we stress that the conventional optical design idea involving balancing and reduction of aberrations can be applied to

systems in which Gaussian beams are to propagate. For example, a *beam expander*, of which one form is shown in [Figure 20.5.33](#), is an afocal system intended to do what its name implies: if it has aberrations

Lens images point at infinity to  $F'$   
 therefore  $QA' + A'F' = AF'$  (Fermat)  
 $AF' - A'F' = AF' - AF = \text{constant}$  (by property of hyperbola)  
 $= BB'$

$QA' = AA' \sin \theta$   
 therefore  $AA' \sin \theta = BB'$

$$(AA'/BB')^2 = 1/\sin^2 \theta$$

**FIGURE 20.5.33**

as an afocal system, the output beam from a Gaussian input beam will not have truly plane or spherical phase fronts.

### Non-Gaussian Beams from Lasers

Not all lasers produce Gaussian beams, even ignoring the inevitable truncation effects of resonator mirrors. Some gas lasers (e.g., helium-neon at any of its lasing wavelengths) produce Gaussian beams when they are in appropriate adjustment, but they can produce off-axis modes with more structure than a Gaussian beam. Other gas lasers (e.g., copper vapor lasers) produce beams with a great many transverse modes covering an angular range of a few milliradians in an output beam perhaps 20 mm across. Some solid-state lasers, e.g., ruby, may produce a very non-Gaussian beam because of optical inhomogeneities in the ruby. Laser diodes, which as already mentioned are becoming increasingly useful as very compact coherent sources, whether cw or pulsed, produce a single strongly divergent transverse mode which is wider across one direction than the other. This mode can be converted into a circular section of approximately Gaussian profile by means of a prism system, as in [Figure 20.5.24](#).

## 20.6 Water Desalination

---

*Noam Lior*

### Introduction and Overview

Water desalination is a process that separates water from a saline water solution. The natural water cycle is the best and most prevalent example of water desalination. Ocean waters evaporate due to solar heating and atmospheric influences; the vapor consisting mostly of fresh water (because of the negligible volatility of the salts at these temperatures) rises buoyantly and condenses into clouds in the cooler atmospheric regions, is transported across the sky by cloud motion, and is eventually deposited back on the earth surface as fresh water rain, snow, and hail. The global freshwater supply from this natural cycle is ample, but many regions on Earth do not receive an adequate share. Population growth, rapidly increasing demand for fresh water, and increasing contamination of the available natural fresh water resources render water desalination increasingly attractive. Water desalination has grown over the last four decades to an output of about 20 million m<sup>3</sup> of fresh water per day, by about 10,000 sizeable land-based water desalination plants.

The salt concentration in the waters being desalted ranges from below 100 ppm wt. (essentially fresh water, when ultrapure water is needed), through several thousand parts per million (brackish waters unsuitable for drinking or agricultural use) and seawater with concentrations between 35,000 and 50,000 ppm. Official salt concentration limits for drinkable water are about 1000 ppm, and characteristic water supplies are restricted to well below 500 ppm, with city water in the United States being typically below 100 ppm. Salinity limits for agricultural irrigation waters depend on the type of plant, cultivation, and soil, but are typically below 2000 ppm.

Many ways are available for separating water from a saline water solution. The oldest and still prevalent desalination process is distillation. The evaporation of the solution is effected by the addition of heat or by lowering of its vapor pressure, and condensation of these vapors on a cold surface produces fresh water. The three dominant distillation processes are multistage flash (MSF), multi-effect (ME), and vapor compression (VC). Until the early 1980s the MSF process was prevalent for desalination. Now membrane processes, especially reverse osmosis (RO), are economical enough to have taken about one third of the market. In all membrane processes separation occurs due to the selective nature of the permeability of a membrane, which permits, under the influence of an external driving force, the passage of either water or salt ions but not of both. The driving force may be pressure (as in RO), electric potential (as in electrodialysis, ED), or heat (as in membrane distillation, MD). A process used for low-salinity solutions is the well-known ion exchange (IE), in which salt ions are preferentially adsorbed onto a material that has the required selective adsorption property and thus reduce the salinity of the water in the solution.

The cost of desalted water is comprised of the capital cost of the plant, the cost of the energy needed for the process, and the cost of operation and maintenance staff and supplies. In large seawater desalination plants the cost of water is about \$1.4 to \$2/m<sup>3</sup>, dropping to less than \$1/m<sup>3</sup> for desalting brackish water. A methodology for assessing the economic viability of desalination in comparison with other water supply methods is described by Kasper and Lior (1979). Desalination plants are relatively simple to operate, and progress toward advanced controls and automation is gradually reducing operation expenses. The relative effect of the cost of the energy on the cost of the fresh water produced depends on local conditions, and is up to one half of the total.

The boiling point of a salt solution is elevated as the concentration is increased, and the **boiling point elevation** is a measure of the energy needed for separation. Thermodynamically reversible separation defines the minimal energy requirement for that process. The minimal energy of separation  $W_{\min}$  in such a process is the change in the Gibbs free energy between the beginning and end of the process,  $\Delta G$ . The minimal work when the number of moles of the solution changes from  $n_1$  to  $n_2$  is thus

$$W_{\min} = \int_{n_1}^{n_2} (\Delta G) dn_w \quad (20.6.1)$$

The minimal energy of separation of water from seawater containing 3.45 wt.% salt, at 25°C, is 2.55 kJ/(kg fresh water) for the case of zero fresh water recovery (infinitesimal concentration change) and 2.91 kJ/(kg fresh water) for the case of 25% freshwater recovery.  $W_{\min}$  is, however, severalfold smaller than the energy necessary for water desalination in practice. Improved energy economy can be obtained when desalination plants are integrated with power generation plants (Aschner, 1980). Such dual-purpose plants save energy but also increase the capital cost and complexity of operation.

Two aspects of the basically simple desalination process require special attention. One is the high-corrosivity of seawater, especially pronounced in the higher-temperature distillation processes, which requires the use of corrosion-resistant expensive materials. Typical materials in use are copper–nickel alloys, stainless steel, titanium, and, at lower temperatures, fiber-reinforced polymers (George et al., 1975). Another aspect is scale formation (Glater et al., 1980; Heitman, 1990). Salts in saline water, particularly calcium sulfate, magnesium hydroxide, and calcium carbonate, tend to precipitate when a certain temperature and concentration are exceeded. The precipitate, often mixed with dirt entering with the seawater and with corrosion products, will gradually plug up pipes, and when depositing on heat transfer surfaces reduces heat transfer rates and thus impairs plant performance. While the ambient-temperature operation of membrane processes reduces scaling, membranes are much more susceptible not only to minute amounts of scaling or even dirt, but also to the presence of certain salts and other compounds that reduce their ability to separate salt from water. To reduce corrosion, scaling, and other problems, the water to be desalted is pretreated. The pretreatment consists of filtration, and may include removal of air (deaeration), removal of CO<sub>2</sub> (decarbonation), and selective removal of scale-forming salts (softening). It also includes the addition of chemicals that allow operation at higher temperatures without scale deposition, or which retard scale deposition and/or cause the precipitation of scale which does not adhere to solid surfaces, and that prevent foam formation during the desalination process.

Saline waters, including seawater, contain, besides a variety of inorganic salts, also organic materials and various particles. They differ in composition from site to site, and also change with time due to both natural and person-made causes. Design and operation of desalination plants requires good knowledge of the saline water composition and properties (Fabuss, 1980; Heitman, 1991).

The major water desalination processes that are currently in use or in advanced research stages are concisely described below. Information on detailed modeling can be found in the references.

## Distillation Processes

### Multistage Flash Evaporation (MSF)

Almost all of the large desalination plants use the MSF process shown schematically in [Figure 20.6.1](#). A photo of an operating plant is shown in [Figure 20.6.2](#). The seawater feed is preheated by internal heat recovery from condensing water vapor during passage through a series of stages, and then heated to its top temperature by steam generated by an external heat source. The hot seawater then flows as a horizontal free-surface stream through a series of “stages,” created by vertical walls which separate the vapor space of each stage from the others. These walls allow the vapor space of each stage to be maintained at a different pressure, which is gradually decreased along the flow path due to the gradually decreasing temperature in the condenser/seawater-preheater installed above the free stream. The seawater is superheated by a few degrees celsius relative to the vapor pressure in each stage it enters, and consequently evaporates in each stage along its flow path. The latent heat of the evaporation is supplied by equivalent reduction of the sensible heat of the evaporating water, thus resulting in a gradual lowering of the stream temperature. The evaporation is vigorous, resulting in intensive bubble generation and growth with accompanying stream turbulence, a process known as **flash evaporation** (Lior and Greif, 1980; Miyatake et al., 1992; 1993). One of the primary advantages of the MSF process is the fact that evaporation occurs

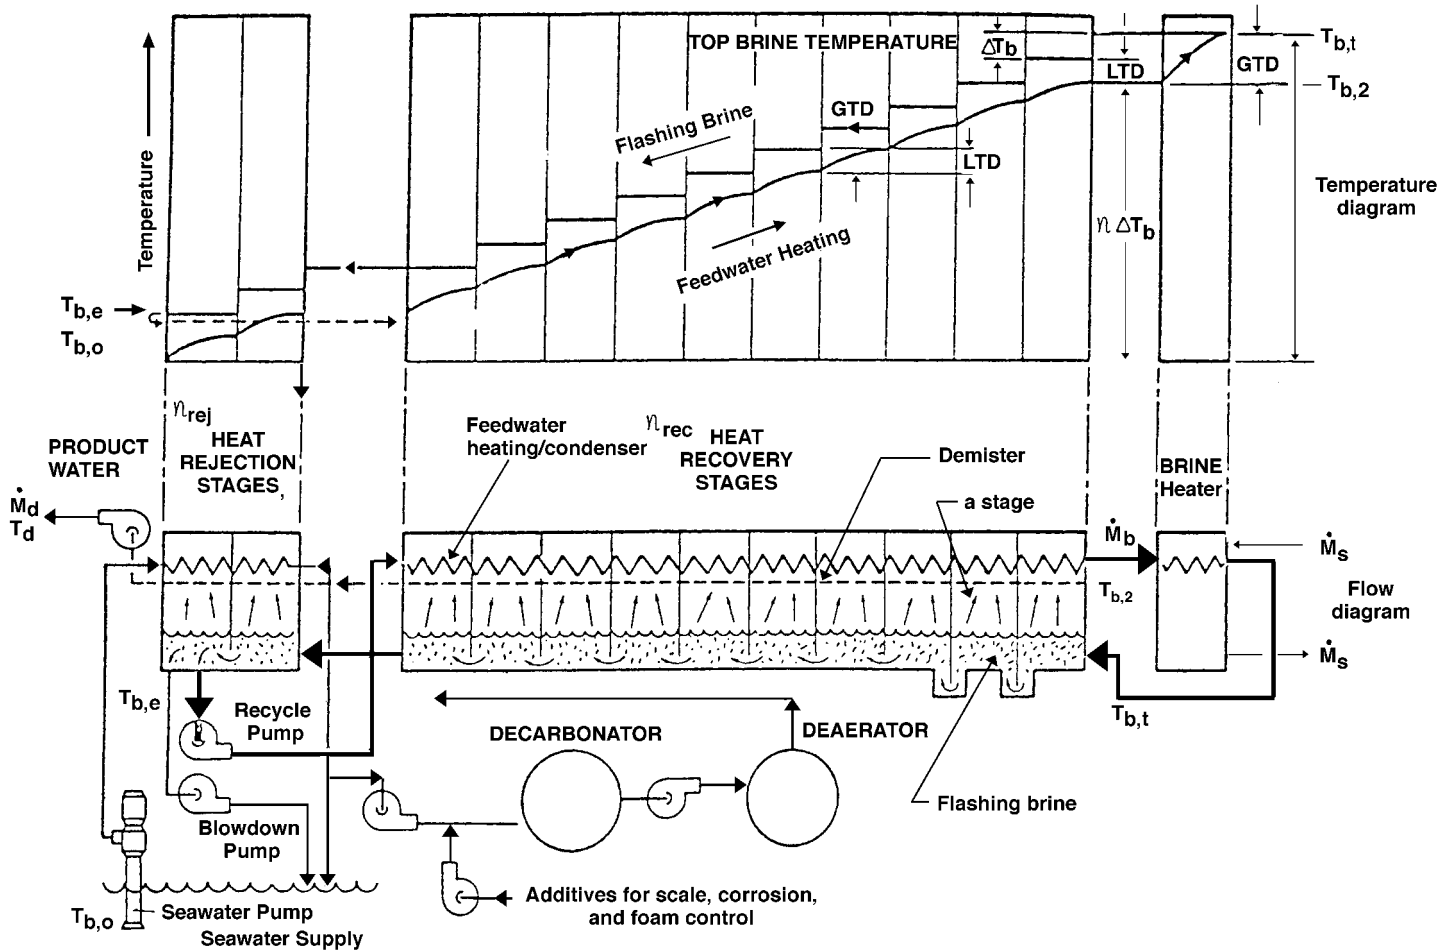

FIGURE 20.6.1 Schematic flow and temperature diagram of the MSF process, for a recirculation type plant.

**FIGURE 20.6.2** One of the six units of the 346,000 m<sup>3</sup>/day MSF desalination plant Al Taweelah B in Abu Dhabi, United Arab Emirates. (Courtesy of Italmimpianti S. p. A.) It is a dual-purpose plant, composed of six identical power and desalination units. Five of the six boilers are seen in the background. The desalination units were in 1996 the largest in the world. They have 17 recovery and 3 reject stages and a performance ratio (PR) of 8.1. The plant also produces 732 MWe of power.

from the saline water stream and not on heated surfaces (as in other distillation processes such as submerged tube and ME evaporation) where evaporation typically causes scale deposition and thus gradual impairment of heat transfer rates. Also, the fact that the sensible heat of water is much smaller than its latent heat of evaporation, where the specific heat  $c_p = 4.182$  kJ/kg/°C change of water temperature and the latent heat is  $h_{fg} = 2378$  kJ/kg, and the fact that the top temperature is limited by considerations of scaling and corrosion, dictate the requirement for a very large flow rate of the evaporating stream. For example (in the following, the subscripts  $b$ ,  $d$ , and  $s$  refer to brine, distillate, and steam, respectively), operating between a typical top temperature  $T_{b,t}$  of 90°C at the inlet to the evaporator and an exit temperature  $T_{b,e}$  of 40°C corresponding to the ambient conditions, the overall temperature drop of the evaporating stream is 50°C. By using these values, the heat balance between the sensible heat of the water stream, flowing at a mass flow rate  $\dot{m}_b$ , and the latent heat needed for generating water vapor (distillate) at a mass flow rate  $\dot{m}_d$  is

$$(\dot{m}_b - \dot{m}_d)c_p(T_{b,t} - T_{b,e}) \approx \dot{m}_d h_{fg} \quad (20.6.2)$$

which yields the brine-to-product mass flow ratio as

$$\frac{\dot{m}_b}{\dot{m}_d} = \frac{h_{fg}}{c_p(T_{b,t} - T_{b,e})} + 1 = \frac{2378}{(4.182)(50)} + 1 = 12.37 \quad (20.6.3)$$

Therefore, 12.37 kg of saline water are needed to produce 1 kg of distillate. This high flow rate incurs corresponding pumping equipment and energy expenses, sluggish system dynamics, and, since the stream level depth is limited to about 0.3 to 0.5 m for best evaporation rates, also requires large evaporator vessels with their associated expense.

The generated water vapor rises through a screen (“demister”) placed to remove entrained saline water droplets. Rising further, it then condenses on the condenser tube bank, and internal heat recovery is

achieved by transferring its heat of condensation to the seawater feed that is thus being preheated. This internal heat recovery is another of the primary advantages of the MSF process. The energy performance of distillation plants is often evaluated by the *performance ratio*, PR, typically defined as

$$PR \equiv \frac{\dot{m}_d}{\dot{m}_s} \tag{20.6.4}$$

where  $\dot{m}_s$  is the mass flow rate of heating steam. Since the latent heat of evaporation is almost the same for the distillate and the heating steam, PR is also the ratio of the heat energy needed for producing one unit mass of product (distillate) to the external heat actually used for that purpose. Most of the heating of the brine stream to the top temperature  $T_{b,t}$  is by internal heat recovery, and as seen in Figure 20.6.1, the external heat input is only the amount of heat needed to elevate the temperature of the preheated brine from its exit from the hottest stage at  $T_{b,2}$  to  $T_{b,t}$ . Following the notation in Figure 20.6.1, and using heat balances similar to that in Equation (20.6.3) for the brine heater and flash evaporator, the PR can thus also be defined as

$$PR = \frac{\dot{m}_b \overline{(c_{p,b})}_{e \rightarrow t} (T_{b,t} - T_{b,e}) / h_{fg,b}}{\dot{m}_b \overline{(c_{p,b})}_{2 \rightarrow t} (T_{b,t} - T_{b,2}) / h_{fg,s}} \approx \frac{T_{b,t} - T_{b,e}}{T_{b,t} - T_{b,2}} \tag{20.6.5}$$

where  $\overline{(c_{p,b})}_{e \rightarrow t}$  and  $\overline{(c_{p,b})}_{2 \rightarrow t}$  are the specific heats of brine, the first averaged over the temperature range  $T_{b,e} \rightarrow T_{b,t}$  and the second over  $T_{b,2} \rightarrow T_{b,t}$ . The rightmost expression in Equation (20.6.5) is nearly correct because the specific heat of the brine does not change much with temperature, and the latent heat of evaporation of the brine is nearly equal to the latent heat of condensation of the heating steam. It is obvious from Equation (20.6.5) that PR increases as the top heat recovery temperature  $T_{b,2}$  (at the exit from the condenser/brine-preheater) increases. It is also obvious (even from just examining Figure 20.6.1) that increasing the number of stages (matched with a commensurate increase in condenser heat transfer area and assuming no significant change in the overall heat transfer coefficient) for a given  $T_{b,t}$ , will raise the flash evaporator inlet temperature  $T_{b,3}$ , which will lead to a rise in  $T_{b,2}$  and thus also in the PR.

Assuming that the temperature drop of the flashing brine,  $\Delta T_b$ , is the same in each stage, the relationship between the number of stages ( $n$ ) and the performance ratio is

$$PR = \frac{1}{\frac{LTD}{T_{b,t} - T_{b,e}} + \frac{1}{n}} \tag{20.6.6}$$

where LTD is the lowest temperature difference between the flashed vapor and the heated feedwater, in each stage (Figure 20.6.1). Equation (20.6.6) shows that increasing the number of stages increases the PR. This implies that more heat is then recovered internally, which would thus require a larger condenser/brine-preheater heat transfer area. The required heat transfer area,  $A$ , per unit mass of distillate produced for the entire heat recovery section (composed of  $n_{rec}$  stages), and taking average values of the overall vapor-to-feedwater heat transfer coefficient  $U$  and LMTD, is thus

$$A = n_{rec} A_n = n_{rec} \frac{h_{b,fg}}{U(LMTD)} \tag{20.6.7}$$

LMTD, the log-mean temperature difference between the vapor condensing on the tubes and the heated brine flowing inside the tubes, for an average stage is

$$\text{LMTD} = \frac{\text{GTD} - \text{LTD}}{\ln \frac{\text{GTD}}{\text{LTD}}} = \frac{(T_{b,t} - T_{b,2}) - \text{LTD}}{\ln \left( \frac{T_{b,t} - T_{b,2}}{\text{LTD}} \right)} \quad (20.6.8)$$

where GTD is the greatest temperature difference between the flashing brine and the brine heated in the condenser. The size of the heat transfer area per unit mass of distillate is

$$A = \frac{h_{fg,b}}{U} \frac{n_{\text{rec}}}{(T_{b,t} - T_{b,e})} \ln \left( \frac{n_{\text{rec}}}{n_{\text{rec}} - PR} \right) \quad (20.6.9)$$

Examination of this equation will show that the required heat transfer area for the heat recovery section per unit mass of distillate produced,  $A$ , increases significantly when  $PR$  is increased, and decreases slightly as the number of heat recovery stages,  $n_{\text{rec}}$ , is increased.

The MSF plant shown in Figure 20.6.1 is of the *recirculation* type, where not all of the brine stream emerging from the last evaporation stage is discharged from the plant (as it would have been in a *once-through* type of plant). A fraction of the emerging brine is mixed with pretreated seawater and recirculated into the condenser of the heat recovery section of the plant. Since only a fraction of the entire stream in this configuration is new seawater, which needs to be pretreated (removal of air and  $\text{CO}_2$ , i.e., deaeration and decarbonation, and the addition of chemicals that reduce scale deposition, corrosion, and foaming), the overall process cost is reduced. The recirculation plant is also easier to control than the once-through type.

While most of the energy exchange in the plant is internal, steady-state operation requires that energy in an amount equal to all external energy input be also discharged from the plant. Consequently, the heat supplied in the brine heater (plus any pumping energy) is discharged in the heat rejection stages section of the plant (Figure 20.6.1). Assuming an equal temperature drop in each stage, and that the pumping energy can be neglected relative to the heat input in the brine heater, indicates that the ratio of the number of the heat-recovery to heat-rejection stages is approximately equal to the performance ratio  $PR$ .

Further detail about MSF desalination can be found in Steinbruchel and Rhinesmith, (1980) and Khan (1986). A detailed design of an MSF plant producing 2.5 million gals. of freshwater per day was published by the U.S. government (Burns and Roe, 1969).

### Multi-Effect Distillation (ME)

The principle of the ME distillation process is that the latent heat of condensation of the vapor generated in one effect is used to generate vapor in the next effect, thus obtaining internal heat recovery and good energy efficiency. Several ME plant configurations, most prominently the horizontal tube ME (HTME, shown in Figure 20.6.3) and the vertical tube evaporator (VTE, shown schematically in Figure 20.6.4) are in use. In the HTME, vapor is circulated through a horizontal tube bundle, which is subjected to an external spray of somewhat colder saline water. The vapor flowing in these spray-cooled tubes condenses, and the latent heat of condensation is transferred through the tube wall to the saline water spray striking the exterior of the tube, causing it to evaporate. The vapor generated thereby flows into the tubes in the next effect, and the process is repeated from effect to effect.

In the VTE the saline water typically flows downward inside vertical tubes and evaporates as a result of condensation of vapor coming from a higher temperature effect on the tube exterior. While internal heat recovery is a feature common to both MSF and ME processes, there are at least three important differences between them. One is that evaporation in the ME process occurs on the heat transfer surfaces (tubes), while in the MSF process it takes place in the free stream. This makes the ME process much more susceptible to scale formation. At the same time, the heat transfer coefficient between the vapor and the preheated brine is lower in the MSF process because the heated brine does not boil. In the ME

**FIGURE 20.6.3** Two HTME desalination units, each producing 5000 m<sup>3</sup>/day, in St. Croix, U.S. Virgin Islands. (Courtesy of I.D.E. Technologies Ltd.)

process it does boil, and it is well known that boiling heat transfer coefficients are significantly higher than those where the heating does not result in boiling. In using direct transfer of latent heat of condensation to latent heat of evaporation, instead of sensible heat reduction to latent heat of evaporation as in MSF, the ME process requires a much smaller brine flow than the MSF. Limiting brine concentration in the last effect to about three times that of the entering seawater, for example, requires a brine flow of only about 1.5 times that of the distillate produced. At the same time, a pump (although much smaller than the two pumps needed in MSF) is needed for each effect.

The PR of ME plants is just slightly lower than the number of effects, which is determined as an optimized compromise between energy efficiency and capital cost. Six effects are typical, although plants with as many as 18 effects have been built.

Further detail about ME desalination can be found in Steinbruchel and Rhinesmith (1980) and Standiford, (1986a).

### Vapor Compression Distillation (VC)

As stated earlier, the vapor pressure of saline water is lower than that of pure water at the same temperature, with the pressure difference proportional to the boiling point elevation of the saline water. Desalination is attained here by evaporating the saline water and condensing the vapor on the pure water. Therefore, the pressure of the saline water vapor must be raised by the magnitude of that pressure difference, plus some additional amount to compensate for various losses. This is the principle of the vapor compression desalination method. Furthermore, as shown in [Figure 20.6.5](#), the heat of condensation of the compressed vapor is recovered internally by using it to evaporate the saline water. Additional heat recovery is obtained by transferring heat from the concentrated brine effluent and the produced freshwater (which need to be cooled down to as close to ambient conditions as possible anyway) to the feed saline water which is thus preheated. The schematic flow diagram in [Figure 20.5.5](#) shows a design in which the preheated seawater is sprayed onto a bank of horizontal tubes carrying condensing compressed vapor at a temperature higher than that of the seawater. The spray thus evaporates on contact with the exterior of the tube and provides the cooling needed for the internal condensation. Considering the fact that the energy required for vapor compression over a typical overall temperature difference of 4°C and a vapor compressor efficiency of 0.8 is 34 kJ/kg (easily calculated from an enthalpy balance), and that the latent

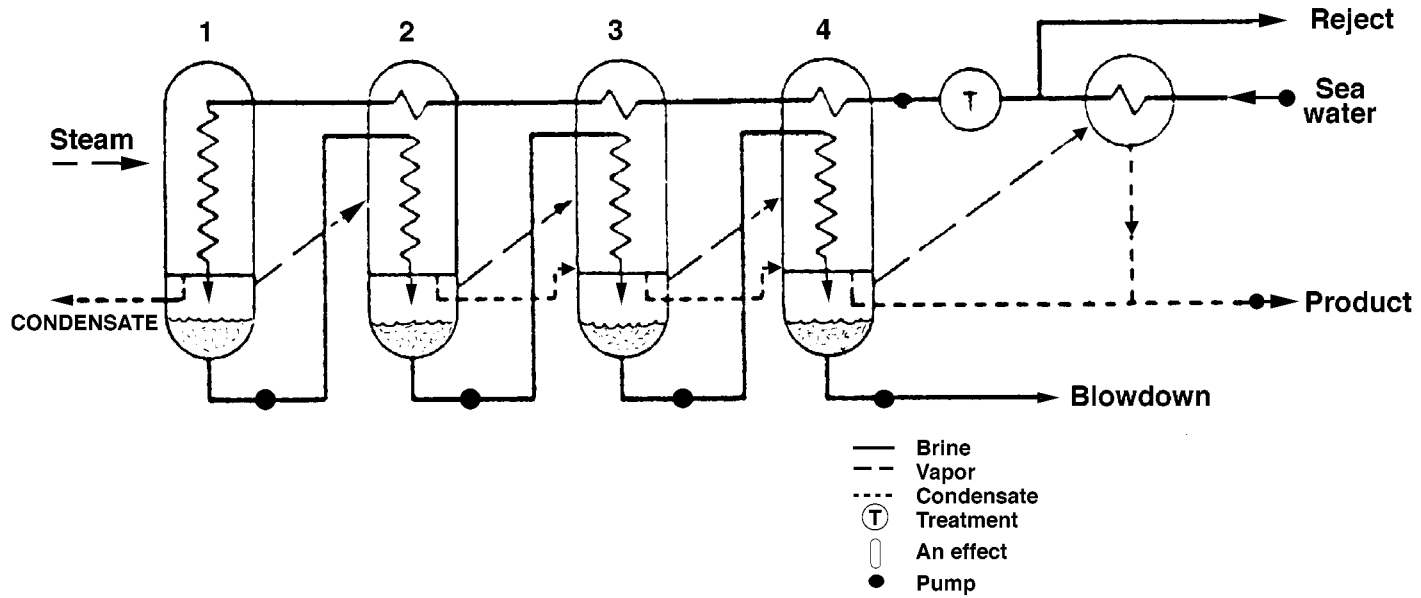

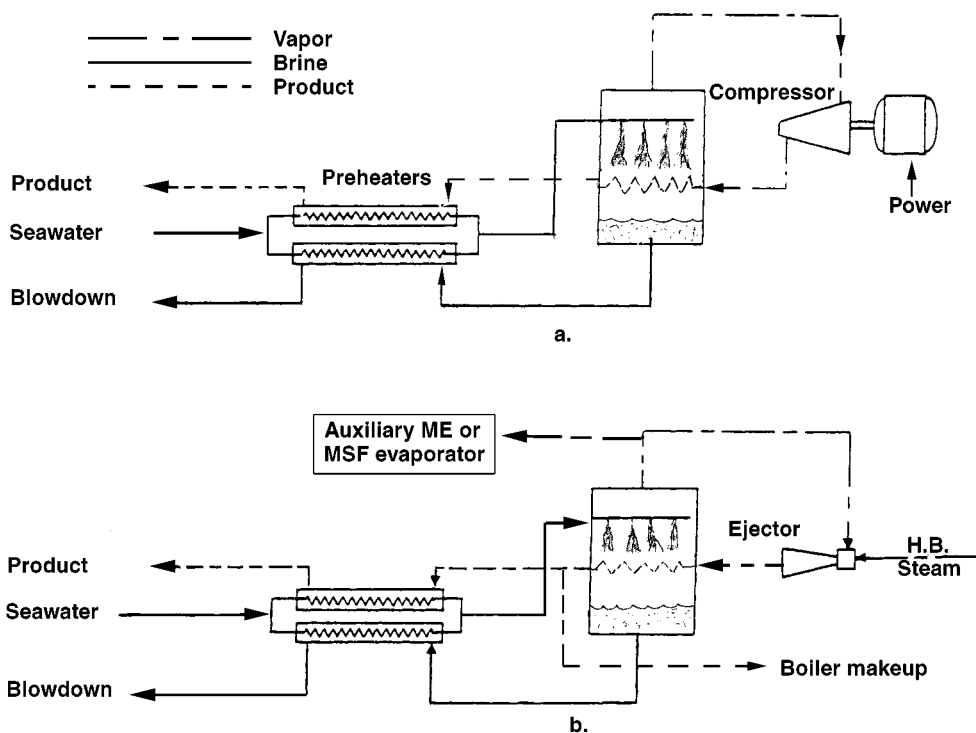

FIGURE 20.6.4 Simplified schematic flow diagram of a typical four-effect VTE desalination plant.

**FIGURE 20.6.5** Schematic flow diagram of a basic horizontal-tube VC desalination plant (a) with mechanical, motor-driven compressor; (b) with a thermo-compressor, using an ejector.

heat of condensation is about 2400 kJ/kg, one can see that a small amount of compression energy enables a large amount of heat to be used internally for desalination. One can thus envisage the VC plant as a large flywheel, wheeling a large amount of energy around at the expense of a small amount needed for sustaining its motion.

The compressor can be driven by electric motors, gas or steam turbines, or internal combustion (usually diesel) engines. The compressor can also be a steam-driven ejector (Figure 20.6.5b), which improves plant reliability because of its simplicity and absence of moving parts, but also reduces its efficiency because an ejector is less efficient than a mechanical compressor. In all of the mentioned thermally driven devices, turbines, engines, and the ejector, the exhaust heat can be used for process efficiency improvement, or for desalination by an additional distillation plant.

Figure 20.6.6 shows a multi-effect VC plant. Using more than a single effect reduces the vapor volume that needs to be compressed. Furthermore, the overall required heat transfer area is also decreased because much of the single-phase heat transfer process in the preheater of the single-effect plant is replaced by the high-heat-transfer condensation–evaporation processes in the effects. Although the ME feature also increases the required compression ratio, the cost of produced water is reduced overall.

Further detail about VC desalination can be found in Steinbruchel and Rhinesmith (1980), Khan (1986), and Standiford, (1986b).

### Solar Distillation

The benefits of using the nonpolluting and practically inexhaustible energy of the sun for water desalination are obvious. Furthermore, many water-poor regions also have a relatively high solar flux over a large fraction of the time. The major impediment in the use of solar energy is economical: the diffuse nature of solar energy dictates the need for constructing a large solar energy collection area. For example,

**FIGURE 20.6.6** Schematic flow diagram of a ME vapor compression submerged-tube desalination plant with three effects.

assuming a single-effect solar still efficiency of 50% (which is the upper practical limit for conventional designs), the still would produce at most about 3.5 to 4.8 kg fresh water per m<sup>2</sup> per day, or a 208 to 286 m<sup>2</sup> solar still would be required to produce 1 m<sup>3</sup> of fresh water per day. More realistic still efficiencies increase the area requirement about twofold.

Shown in [Figure 20.6.7](#), a typical solar still consists of a saline water container in which the water is exposed to the sun and heated by it. The temperature rise to above ambient causes net evaporation of the saline water, thus separating pure water vapor from the solution. The vapor condenses on the colder cover, and this distilled water flows to collection troughs.

**FIGURE 20.6.7** A typical basin-type solar still.

Solar stills of the type depicted in [Figure 20.6.7](#), in many sizes and constructional variants, have been built and used successfully in many countries in the world. They are simple, easy to construct, reliable, and require very little maintenance although in some regions the covers must be cleaned frequently from accumulated dust or sand.

Since the heat of condensation in single-effect stills of the type shown in [Figure 20.6.7](#) is lost to the ambient, more-energy-efficient operation can obviously be achieved in a multi-effect design, where the

heat of condensation is used to evaporate additional saline water. A number of such stills were built and tested successfully, but are not commercially competitive yet.

Solar stills integrate the desalination and solar energy collection processes. Another approach to solar desalination is to use separately a conventional desalination process and a suitable solar energy supply system for it. Any compatible desalination and solar energy collection processes could be used. Distillation, such as MSF or ME, can be used with heat input from solar collectors, concentrators, or solar ponds (Hoffman, 1992; Glueckstern, 1995). Net average solar energy conversion efficiencies of solar collectors (Rabl, 1985; Lior, 1991) are about 25% and of solar ponds (Lior, 1993) about 18%, similar to the efficiencies of solar stills, but the MSF or ME plants can operate at performance ratios of 10 or more, thus basically increasing the freshwater production rate by at least tenfold, or reducing the required solar collection area by at least tenfold for the same production rate.

Solar or wind energy can also be used for desalination processes that are driven by mechanical or electrical power, such as VC, RO, and ED. The solar energy can be used to generate the required power by a variety of means, or photovoltaic cells can be used to convert solar energy to electricity directly.

## Freeze Desalination

It is rather well known that freezing of saline water solutions is an effective separation process in that it generates ice crystals that are essentially salt-free water, surrounded by saline water of higher concentration. This process requires much less energy than distillation, and the problems of corrosion and scaling are markedly reduced due to the much lower operating temperatures. Several pilot plants were constructed and have proven concept viability. Nevertheless, the process has not yet reached commercial introduction for several reasons, such as the difficulty in developing efficient and economical compressors for vapor with the extremely high specific volume at the low process pressure, and difficulties in maintaining the vacuum system leak free and in effecting reliable washing of the ice crystals. A review of freeze desalination processes is given by Tleimat (1980).

## Membrane Separation Processes

### Reverse Osmosis (RO)

Separation of particulate matter from a liquid by applying pressure to the liquid and passing it through a porous membrane, whereby particles larger than the pore size remain on the upstream side of the membrane and the liquid flows to its downstream side, is well known as *filtration*. Semipermeable very dense membranes that actually separate salt molecules (ions) from the water, by similarly keeping the salt on the upstream side and allowing the pressurized pure water to flow through the membrane, were developed in the 1950s. The reverse of this process, **osmosis**, is well known: for example, if a membrane is placed to separate water from an aqueous salt solution, and the membrane is semipermeable (here meaning that it permits transfer of water only, not the salt components in the aqueous solution), the water will tend naturally to migrate through this membrane into the salt solution. Osmosis is, for example, the major mass transport phenomenon across living cells. The driving force for this water flux is proportional to the concentration difference between the two sides of the membrane, and is exhibited as the so-called **osmotic pressure**, which is higher by 2.51 MPa on the water side of the membrane for typical seawater at 25°C. If a pressure higher than the osmotic pressure is applied on the saline solution side of the membrane, the water flux can be reversed to move pure water across the membrane from the saline solution side to the pure water one. This process is called *reverse osmosis* (and sometimes *hyperfiltration*), and is the basic principle of RO desalination.

Unlike filtration of particulates, the selective “filtration” of the water in RO is not due to the relationship of the membrane pore size to the relative sizes of the salt and water molecules. Rather, one way to explain the process is that the very thin active surface layer of the membrane forms hydrogen bonds with water molecules and thus makes them unavailable for dissolving salt. Salt thus cannot penetrate through that layer. Water molecules approaching that layer are, however, transported through it by forming

such hydrogen bonds with it and in that process displacing water molecules that were previously hydrogen bonded at these sites. The displaced water molecules then move by capillary action through the pores of the remainder of the membrane, emerging at its other side.

The most prevalent membrane configurations used in RO plants are of the spiral-wound or hollow-fiber types. The basic spiral-wound-type module (Figure 20.6.8) is made of two sheets placed upon each other and rolled together in an increasing diameter spiral around a cylindrical perforated tube. One of the sheets is in the form of a sandwich typically composed of five layers bonded together along three edges. The two outer layers are the semipermeable membranes. Each of them is backed by a porous material layer for mechanical strength, and the very central layer is a thicker porous material layer that takes up the produced fresh water. The second sheet is a porous mesh through which the high-pressure saline water feed is passed in an axial direction. Product water separates from the saline solution and permeates through the two adjacent semipermeable membranes into the central product water-carrying layer, which conducts it spirally to the unbonded edge of the “sandwich” and to the inner perforated tube. The semipermeable membranes are typically made from cellulose acetate, and more recently from composites of several polymers.

FIGURE 20.6.8 A spiral-wound RO membrane element.

Hollow fiber modules have a configuration similar to a shell-and-tube heat exchanger, with the fibers taking the place of the tubes. A very large number of typically 25 to 250  $\mu\text{m}$  outside-diameter semipermeable hollow fibers (wall thickness typically 5 to 50  $\mu\text{m}$ ) are bundled together and placed in a saline water pressure vessel. The hollow core of each fiber is sealed on one end. The pressurized saline water is brought into the module (through a central porous feed tube, Figure 20.6.9) to circulate on the exterior surface of the fibers, and water permeates through the fiber wall into its hollow core, through which it flows to a permeate collection manifold at the open end of the fiber bundle. The increasingly concentrated saline water flows radially and is discharged at the exterior shell of the bundle. The hollow fibers are typically made of polyamide or cellulose triacetate, and offer about 20 fold more surface (separation) area per unit volume than the spiral-wound configuration.

The basic approximate equation for the separation process gives the water flux  $\mathcal{M}_w''$  ( $\text{kg}/\text{m}^2\text{sec}$ ) across an RO membrane, in the absence of fouling, as

$$\mathcal{M}_w'' = K_{pe} K_{cf} \left[ (P_f - P_p) - (\pi_f - \pi_p) \right] \quad (20.6.10)$$

FIGURE 20.6.9 A hollow-fiber RO membrane module. (Du Pont Permasep™.)

where

$K_{pe}$  water permeability constant of the membrane (in  $\text{kg}/\text{m}^2\text{sec Pa}$ ), typically increasing strongly as the temperature rises: a plant designed to operate at  $20^\circ\text{C}$  may produce up to 24% more water if the water temperature is  $28^\circ\text{C}$ ,

$K_{cf}$  compaction correction factor (dimensionless) which corrects for the fact that the flux is reduced due to densification of the barrier layer (a phenomenon similar to creep) of the membrane, and which increases with the operating pressure and temperature. It is often calculated by the relationship

$$K_{cf} = BC(T)C(P)C(t) \tag{20.6.11}$$

where  $B$  is a constant,

$C(T)$  represents the temperature dependence of the Compaction Correction Factor for the particular membrane of interest,

$C(P)$  represents its pressure dependence: while a higher pressure difference across the membrane is shown in Equation (20.6.10) to increase the water flux, higher feed pressure ( $P_f$ ) also tends to compact the membrane and thus reduce its water flux, typically according to

$$C(P) = P_f^n \tag{20.6.12}$$

where  $n$  is a negative number,

and where the time dependence  $C(t)$  is represented by

$$C(t) = t^m \tag{20.6.13}$$

where  $t$  is the operating time (say, in days) and  $m$  is a negative number depending on the membrane.

$P$  water or saline solution pressure (Pa),

$\pi$  osmotic pressure (Pa),

and the subscripts  $f$  and  $p$  pertain to the saline feed water and to the desalted product water, respectively.

The required membrane area  $A$  can be estimated by

$$A = \frac{M_p}{M_p' f} \tag{20.6.14}$$

where  $\mathcal{M}_p$  is the freshwater mass production rate of the plant (kg/sec), and  $f$  ( $0 < f \leq 1.0$ ) is the *area utilization factor* that corrects for the fact that the membrane surface is incompletely in contact with the saline water feed stream due to the porous mesh and other devices, such as turbulence promoters, placed in the feed stream path; in a good design  $f > 0.9$ .

Examination of Equation (20.6.10) shows that water separation rate increases with the water permeability constant  $K_{pe}$ . Unfortunately, so does the salt flux across the membrane, resulting in a saltier product. An approximation for this salt flow is

$$\mathcal{M}_s = KK_s(C_{fm} - C_p) \quad (20.6.15)$$

where

- $\mathcal{M}_s$  salt mass transfer rate across the membrane, kg/sec,
- $K$  a proportionality constant, dimensionless,
- $K_s$  salt permeation constant, kg/sec, which increases with pressure and temperature.

The salinity of the product water ( $C_p$ ) can be estimated by the formula

$$C_p = K_{cp}(1 - \eta)\bar{C} \quad (20.6.16)$$

where

- $K_{cp}$  concentration polarization coefficient,  $\equiv C_{fm}/\bar{C}$  is a measure of the increase of the feedwater salinity at the membrane wall beyond that of the bulk solution,
- $C_{fm}$  salt concentration at the membrane wall,
- $\bar{C}$  bulk salinity of the saline water feed,  $\approx (C_f + C_r)/2$ ,
- $C_r$  salt concentration of the reject brine,
- $\eta$  salt rejection factor,  $\equiv$  (amount of salts rejected by the membrane)/(amount of salts in the brine feed).

The pressure to be used for RO depends on the salinity of the feed water, the type of membrane, and the desired product purity. It ranges from about 1.5 MPa for low feed concentrations or high-flux membranes, through 2.5 to 4 MPa for brackish waters, and to 6 to 8.4 MPa for seawater desalination. In desalination of brackish water, typical product water fluxes through spiral-wound membranes are about 600 to 800 kg/(m<sup>2</sup>day) at a recovery ratio (RR) of 15% and an average salt rejection of 99.5%, where

$$RR = \frac{\mathcal{M}_p}{\mathcal{M}_f} \approx 1 - \frac{C_f}{C_r} \quad (20.6.17)$$

The fluxes in hollow-fiber membranes used in seawater desalination are 20- to 30-fold smaller, but the overall RO system size does not increase, because the hollow-fiber membranes have a much larger surface area per unit volume. The RR and salt rejection ratio are similar to those of spiral-wound membranes.

Since the concentrated reject brine is still at high pressure, it is possible to recover energy by passing this brine through hydraulic turbines, and thus reduce the overall energy consumption by up to 20%. The energy requirements of seawater RO desalination plants with energy recovery are about 5 to 9 kWh, or 18 to 33 MJ, of mechanical or electric power per m<sup>3</sup> fresh water produced. In comparison, the MSF desalination process requires about 120 to 280 MJ of heat and about 15 MJ of mechanical/electric power (for pumping and auxiliaries) per m<sup>3</sup>. The energy requirement of the RO process is thus smaller than that of the MSF process even if the RO energy requirement is multiplied by the thermal-to-mechanical

(or electrical) power conversion factor of 3 to 4. The specific *exergy* consumption of the MSF process using 120°C steam is about 2- to 3-fold higher than that of the RO process, but becomes comparable in magnitude if the steam temperature is lowered to 80°C.

The life of membranes is affected by gradual chemical decomposition or change. For example, cellulose acetate membranes **hydrolyze** with time. The rate of hydrolysis has a steep minimum at a solution pH of 4.5 to 5.0, and increases drastically with temperature.

Membranes are susceptible to plugging by dirt and to deterioration in their selectivity caused by various species present in the saline water. Careful pretreatment of the feed water is therefore necessary. It typically consists of clarification, filtration, chlorination for destroying organic matter and microorganisms, removal of excess chlorine to prevent membrane oxidation, and dosing with additives to prevent calcium sulfate scaling and foam formation. Periodical chemical or mechanical cleaning is also necessary. Pretreatment and cleaning are significant and increasing fractions of the RO plant capital and operating costs.

Further detail about RO desalination can be found in Sourirajan and Matsuura (1985) and Amjad (1993).

### Electrodialysis (ED)

In ED, the saline solution is placed between two membranes, one permeable to cations only and the other to anions only. A direct electrical current is passed across this system by means of two electrodes, cathode and anode, exposed to the solution (Figure 20.6.10). It causes the cations in the saline solution to move toward the cathode, and the anions to the anode. As shown in Figure 20.6.10, the anions can leave the compartment in their travel to the anode because the membrane separating them from the anode is permeable to them. Cations would similarly leave the compartment toward the cathode. The exit of these ions from the compartment reduces the salt concentration in it, and increases the salt concentration in the adjacent compartments. Tens to hundreds of such compartments are stacked together in practical ED plants, leading to the creation of alternating compartments of fresh and salt-concentrated water. ED is a continuous-flow process, where saline feed is continuously fed into all compartments and the product water and concentrated brine flow out of alternate compartments. The flow along the membranes also improves the mass transport there, and the separators between the membranes are constructed to provide good flow distribution and mixing on the membrane surfaces. Membrane sizes are roughly 0.5 × 1 m, spaced about 1 mm apart. Many types of polymers are used to manufacture these ion-exchange selective membranes, which are often reinforced by strong fabrics made from other polymers or glass fibers.

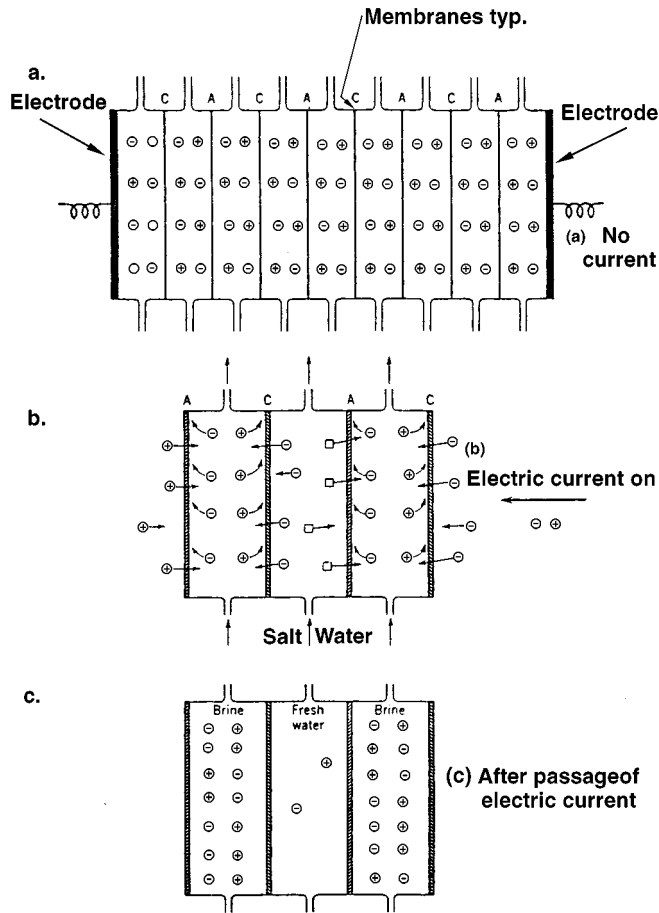

Careful and thorough feed water pretreatment similar to that described in the section on RO is required. Pretreatment needs and operational problems of scaling are diminished in the electro dialysis reversal (EDR) process, in which the electric current flow direction is periodically reversed (say, three to four times per hour), with simultaneous switching of the water flow connections. This also reverses the salt concentration buildup at the membrane and electrode surfaces, and prevents concentrations that cause the precipitation of salts and scale deposition.

The voltage used for ED is about 1 V per membrane pair, and the current flux is of the order of 100 A/m<sup>2</sup> of membrane surface. The total power requirement increases with the feed water salt concentration, amounting to about 10 MW/m<sup>3</sup> product water per 1000 ppm reduction in salinity. About half this power is required for separation and half for pumping. Many plant flow arrangements exist, and their description can be found, along with other details about the process, in Shaffer and Mintz (1980) and Heitman (1991).

### Defining Terms

**Boiling point elevation:** The number of degrees by which the boiling point temperature of a solution is higher than that of the pure solute at the same pressure.

**Flash evaporation:** An evaporation process that occurs when a liquid with a free surface is exposed to its vapor, where the vapor is below the saturation pressure corresponding to the temperature of the liquid.

**FIGURE 20.6.10** The ED process. C and A are cation- and anion-permeable membranes, respectively. Application of electric current causes ion transport in a way that salt is depleted in alternate compartments, and enriched in the remaining ones.

The process is typically vigorous, accompanied by rapid growth of bubbles and associated turbulence in the liquid.

**Hydrolysis:** Decomposition in which a compound is split into other compounds by taking up the elements of water.

**Osmosis:** The diffusion process of a component of a solution (or mixture) across a semipermeable membrane, driven by the concentration difference (or gradient) of that component across the membrane.

**Osmotic pressure:** The minimal pressure that has to be applied to the solution (mixture) on the lower concentration side of a membrane permeable to one solution component, for stopping the osmosis of that component through the membrane.

## Further Information

The major texts on water desalination written since the 1980s are Spiegler and Laird (1980), Khan, (1986) (contains many practical design aspects), Lior (1986) (on the measurements and control aspects), Heitman (1990) (on pretreatment and chemistry aspects), and Spiegler and El-Sayed (1994) (an overview primer). Extensive data sources are provided in George et al. (1975) and M. W. Kellog (1975).

The two major professional journals in this field are *Desalination*, *The International Journal on the Science and Technology of Desalting and Water Purification* and *Membrane Science*, which often addresses membrane-based desalination processes, both published by Elsevier, Amsterdam.

The major professional society in the field is the International Desalination Association (IDA) headquartered at P.O. Box 387, Topsfield, MA 01983. IDA regularly organizes international conferences, promotes water desalination and reuse technology, and is now publishing a trade magazine *The International Desalination & Water Reuse Quarterly*.

The *Desalination Directory* by M. Balaban Desalination Publications, Mario Negri Sud Research Institute, 66030 Santa Maria Imbaro (Ch), Italy, lists more than 5000 individuals and 2000 companies and institutions in the world of desalination and water reuse.

Two useful (though by now somewhat dated) books on desalination are by Howe, E. D. 1974. *Fundamentals of Water Desalination*, Marcel Dekker, New York, and by Porteous, A. 1975. *Saline Water Distillation Processes*, Longman, London.

Much information on oceans and seawater properties is available in the book by Riley, J. P. and Skinner, Eds. 1975. *Chemical Oceanography*, Academic Press, New York.

## 20.7 Noise Control

---

*Malcolm J. Crocker*

### Introduction

Noise is usually defined as unwanted sound. Noise in industry experienced over an extended period can cause hearing loss. Noise in other environments — in buildings, vehicles, and communities from a variety of sources causes speech interference, sleep disturbance, annoyance, and other effects (Crocker, 1997b,d). Noise propagates as sound waves in the atmosphere and as vibration in buildings, machinery, vehicles, and other structures. Noise can be controlled at the *source*, in the *path*, or at the *receiver*. The ear is more sensitive to noise in the mid- to high-frequency range, but fortunately high-frequency is easier to control than low-frequency noise. Several passive methods of noise and vibration control are described. An example of successful noise control is the considerable reduction in passenger jet aircraft noise in the last several years which has made them considerably quieter.

### Sound Propagation

Sound waves propagate rather like ripples on a lake when a stone is thrown in (Crocker, 1997c). The ripples spread out from the source of the disturbance as circular waves until they reach a solid body or boundary (such as the lake edge) where reflections occur. The water does not flow from the source, but the disturbance propagates in the form of momentum and energy which is eventually dissipated. Sound waves in air cannot be seen but behave in a similar manner. Sound waves propagating in three dimensions from a source of sound are spherical rather than circular like the two-dimensional water wave propagation. Sound waves propagate at the wave speed (or *sound speed*  $c$ ) which is dependent only on the absolute temperature  $T$ . It is 343 m/sec (1120 ft/sec) at a normal atmospheric temperature of 20°C. The *wavelength*  $\lambda$  of sound is inversely proportional to the *frequency*  $f$  in cycles/sec (known as hertz or Hz) and is given by  $\lambda = c/f$  Hz. The sound waves result in fluctuations in the air pressure as they propagate. The air pressure difference from the mean atmospheric pressure is defined as the *sound pressure*. A logarithmic measure, the sound pressure level SPL or  $L_p$ , is usually used with sound and noise and the units are *decibels* (dB). The sound pressure level is  $L_p = 10 \log_{10} (p^2 / p_{\text{ref}}^2)$ , where  $p$  is the rms sound pressure and  $p_{\text{ref}}$  is the reference sound pressure 20  $\mu\text{Pa}$  (or  $20 \times 10^{-6}$  N/m<sup>2</sup>). See [Figure 20.7.1](#) (Crocker, 1997c).

### Human Hearing

The human ear has a wide frequency response from about 15 or 20 Hz to about 16,000 Hz (Crocker, 1975; Greenberg, 1997). The ear also has a large dynamic range; the ratio of the loudest sound pressure we can tolerate to the quietest sound that we can hear is about ten million ( $10^7$ ). This is equivalent to 140 dB. The ear can be divided into three main parts: the outer, middle, and inner ear. The outer ear, consisting of the fleshy pinna and ear canal, conducts the sound waves onto the ear drum. The middle ear converts the sound pressure at the ear drum into the mechanical motion of three small bones (named auditory ossicles: malleus, incus, and stapes) which in turn convert the mechanical motion into waves in the inner ear. Hair cells in the inner ear respond to the excitation and send neural impulses along the auditory nerves to the brain ([Figure 20.7.2](#)).

The higher the sound pressure level of a sound, the louder it normally sounds, although the frequency content of the sound is important too. The ear is most sensitive to sound in the mid-frequency range and hears sound only poorly at lower frequencies (below 200 or 300 Hz). Most people have a maximum sensitivity to sound at about 4000 Hz (corresponding to a quarter wave resonance in the ear canal, with a pressure maximum at the eardrum). Electrical filters have been produced corresponding approximately to the frequency response of the ear. The A-weighting filter is the one most used and it filters off a considerable amount of the sound energy at low frequencies. The sound pressure level measured with an A-weighting filter is normally known as the A-weighted sound level (or the sound level for short).

FIGURE 20.7.1 Some typical sound pressure levels.

FIGURE 20.7.2 Cross section of the human ear showing the three main parts: outer, middle, and inner ear.

The anatomy and functioning of the ear are described more completely in several books (Crocker, 1997; Greenberg, 1997).

### Noise Measures

There are several rating measures and descriptors used to determine human response to noise. Only a few of the most important can be discussed here. The reader will find more such measures discussed in the literature. [1] Criteria derived from such measures can be used to produce regulations or legislation.

The speech interference level (SIL) is a measure used to evaluate the effect of background noise on speech communication. The SIL is the arithmetic average of the sound pressure levels of the interfering background noise in the four octave bands with center frequencies of 500, 1000, 2000 and 4000 Hz.<sup>1,6</sup>

The speech interference level of the background noise is calculated; then this may be used in conjunction with Figure 20.7.3 to determine if communication is possible at various distances for different voice levels. This figure is for male voices. Since the average female voice is normally quieter, for female voices the horizontal scale should be moved to the right by 5 dB. Use of the results obtained with Figure 20.7.3 and criteria for various spaces in buildings enable decisions to be made whether they are suitable for their desired uses.

**FIGURE 20.7.3** Recommended distances between speaker and listener for various voice levels for just reliable speech communication. (From C.M. Harris *Handbook of Noise Control*, McGraw-Hill, New York, 1979. With permission.)

The equivalent sound level  $L_{eq}$  is the A-weighted sound pressure level averaged over a suitable time period  $T$ . The averaging time  $T$  can be chosen to be a number of minutes, hours or days, as desired.

$$L_{eq} = 10 \log_{10} \left[ (1/T) \int p_A^2 dt / p_{ref}^2 \right] dB$$

where  $p_A$  is the instantaneous sound pressure measured using an A-weighting frequency filter. The  $L_{eq}$  is also sometimes known as the *average sound level*  $L_{AT}$ .

The *day-night equivalent sound level* (DNL) or  $L_{dn}$  is a measure that accounts for the different human response to sound at night. It is defined (Crocker, 1997d) as:

$$L_{dn} = 10 \log_{10} \left\{ (1/24) \left[ 15 \left( 10^{L_d/10} \right) + 9 \left( 10^{(L_n+10)/10} \right) \right] \right\} \text{ dB}$$

where  $L_d$  is the 15-hr daytime A-weighted equivalent sound level (from 0700 to 2200 hr) and  $L_n$  is the 9-hr nighttime equivalent sound level (from 2200 to 0700 hr). The nighttime level is subjected to a 10-dB penalty because noise at night is known to be more disturbing than noise during the day.

There is some evidence that noise that fluctuates markedly in level is more annoying than noise which is steady in level. Several noise measures have been proposed to try to account for the annoying effect of these fluctuations. The percentile levels are used in some measures. The *percentile level*  $L_n$  is defined to be the level exceeded  $n\%$  of the time (Crocker, 1997d). The A-weighted sound level is normally used in  $L_n$ .

## Response of People to Noise and Noise Criteria and Regulations

In industry, noise is often intense enough to interfere with speech and to create noise conditions that are hazardous to hearing. By using [Figure 20.7.3](#) it is seen that if the SIL is above 50 dB, then the noise will interfere with normal speech communication between male voices at 4 m. If it is above 60 dB, then speech communication even when shouting is barely possible at the same distance. For women the comparable values of SIL are 45 and 55 dB at the same distance. If the SIL is 90 dB, then communication between male voices is only possible at distances less than 0.25 m, even when shouting. A-weighted sound levels are sometimes used instead of SIL values but with somewhat less confidence. It is seen that if one has difficulty in communicating in an industrial situation, then the A-weighted sound level is likely to be above 90 dB. In the United States, OSHA regulations start at this level for an 8-hr period. There is a halving in the allowable exposure time for every 5-dB increase in sound level. See [Table 20.7.1](#). In almost all other countries the allowable exposure time is halved for every 3-dB increase in sound level (Ward, 1997).

**TABLE 20.7.1 Maximum A-Weighted Sound Levels Allowed by the U.S. Occupational Safety and Health Administration (OSHA) for Work Periods Shown during a Workday**

Duration per Day (hr)	Sound Level in dB(A)
8	90
6	92
4	95
3	97
2	100
1.5	102
1	105
0.5	110
0.25 or less	115

Noise in communities is caused by many different sources. In most countries, the maximum equivalent A-weighted sound level  $L_{eq}$  is recommended for evaluating different types of noise source (Gottlob, 1995). In some countries there are regulations which use  $L_{eq}$  for road traffic noise and railroad noise, although some countries use  $L_{10}$  (e.g., the U.K.) or  $L_{50}$  (e.g., Japan) for planning permission in which road traffic noise is of concern (Crocker, 1997d; Gottlob, 1995). In the United States the  $L_{dn}$  has been used for community noise situations involving aircraft noise at airports and road traffic noise. [Table 20.7.2](#) presents levels of noise given by the U.S. EPA and several other bodies to protect public health.

**TABLE 20.7.2 Guidelines from the U.S. Environmental Protection Agency (EPA), World Health Organization (WHO), Federal Interagency on Community Noise (FICON), and Various European Agencies for Acceptable Noise Levels**

Authority	Specified Sound Levels	Criterion
EPA Levels Document	$L_{dn} \leq 55$ dB (outdoors) $L_{dn} \leq 45$ dB (indoors)	Protection of public health and welfare with adequate margin of safety
WHO Document (1995)	$L_{eq} \leq 50/55$ dB (outdoors: day) $L_{eq} \leq 45$ dB (outdoors: night) $L_{eq} \leq 30$ dB (bedroom) $L_{max} \leq 45$ dB (bedroom)	Recommended guideline values (Task Force consensus)
U.S. Interagency Committee (FICON)	$L_{dn} \leq 65$ dB  $65 \leq L_{dn} \leq 70$ dB	Considered generally compatible with residential development Residential use discouraged
Various European road traffic regulations	$L_{eq} \geq 65$ or 70 dB (day)	Remedial measures required

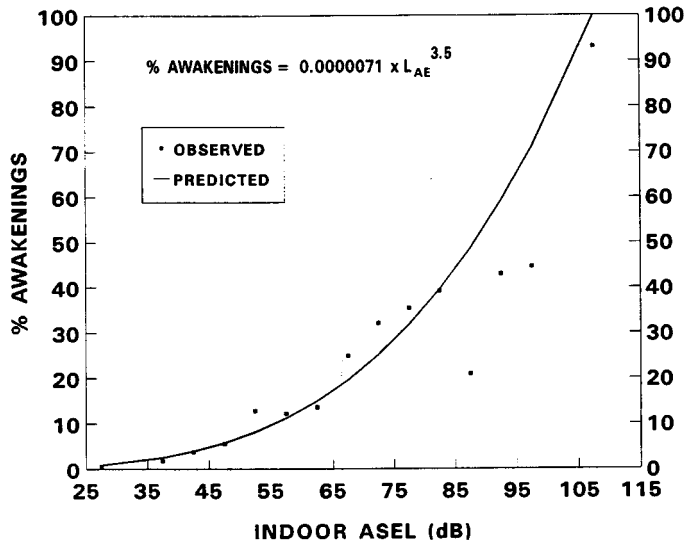

**FIGURE 20.7.4** Percentage of survey respondents highly annoyed vs. day-night equivalent sound level for aircraft, road traffic, and railway noise.

Social surveys in several countries have been used to relate the percentage of respondents highly annoyed by noise to the day-night equivalent sound level,  $L_{dn}$  (Crocker, 1997d; Gottlob, 1995). See Figure 20.7.4. (Finegold et al., 1994). It is seen that many studies have shown that aircraft noise appears to be more annoying than other sources, perhaps because of the larger fluctuation in levels with time compared with the other sources. However, some other studies suggest that railroad noise is less annoying than traffic noise and this is borne out by the lower levels used for railroad noise than traffic noise regulations in several European countries (Gottlob, 1995).

Various investigations have shown that noise disturbs sleep (Crocker, 1997d). It is well known that there are several stages of sleep and that people progress through these stages as they sleep. Noise can change the progress through these stages and if sufficiently intense can awaken the sleeper. Recently, sleep disturbance data from several analyses have been reanalyzed and the preliminary sleep disturbance curve given in Figure 20.7.5 has been proposed. A regression fit to these sleep disturbance data (Finegold et al., 1994) gave the following expression (which is also shown graphically in Figure 20.7.5) (Crocker, 1997d; Finegold et al., 1994):

$$\% \text{ Awakenings} = 7.1 \times 10^{-6} L_{AE}^{3.5}$$

where  $L_{AE}$  is the indoor A-weighted sound exposure level ASEL.

**FIGURE 20.7.5** Proposed sleep disturbance curve: percentage of subjects awakened as a function of indoor sound exposure level.

## Noise Control Approaches

The main noise control approaches include use of sound absorption, enclosures, barriers, and vibration isolation and damping (Crocker, 1997c). Most porous materials absorb sound and those materials specially made for this purpose include materials such as porous foams and fiberglass. However, ordinary materials such as carpets and drapes are also effective and can be used in building spaces to reduce reverberant sound buildup and noise. Although all these materials are rather ineffective at low frequency, at frequencies above 500 to 1000 Hz they can absorb almost all of the sound energy incident on them and in this case are said to have an absorption coefficient  $\alpha$  of one. In industry they are used inside machine enclosures or placed on the walls and inside ceilings of manufacturing buildings to reduce the reverberant noise buildup (Crocker, 1997c).

Enclosures can be used to partially or completely enclose machines (machine enclosures) or to enclose operators of machines (personnel enclosures). The first approach may be regarded as *path* control and the second as *receiver* control. The improvement in noise reduction that these enclosures can achieve is related not only to the so-called transmission loss TL of the enclosure material used,  $TL = 10 \log mf - 34$  dB, where  $m$  is the mass/unit area of the enclosure walls in  $\text{kg/m}^2$  and  $f$  is the frequency in Hz, but also to the absorption coefficient  $\alpha$  by  $10 \log(1/\alpha)$ . Thus, enclosures that have massive walls and absorbing material inside are the most effective at reducing noise both as machine enclosures or personnel enclosures. The enclosures should be well sealed to prevent sound being transmitted through leaks. If it is necessary to have a vent or hole in the enclosure for ventilation or for access, then the vent should be lined with sound-absorbing material and be bent or constructed like a labyrinth to try to reduce the direct transmission of noise through the vent or hole. As the relationship for TL indicates, enclosures are generally more effective at high frequency (Crocker, 1997c).

Barriers are used to shield personnel from sound sources. The effectiveness of a barrier depends not only on the effective height of the barrier in wavelengths, but also how far the receiver point is into the sound shadow. Barriers are thus most effective when they are taller (in wavelengths) and thus best for

high-frequency noise and also best when placed close to the source or close to the receiver, since such placement increases the shadowing effect. Barriers are used in industry where it is desired to shield personnel from machinery noise sources. It is important in such cases to put sound-absorbing material on the ceiling of the building just above the barrier or on walls just behind a barrier where these surfaces could allow the reflection of sound to bypass the barrier and thus severely reduce its effectiveness (Crocker, 1997c).

The vibration isolation of machine sources from their supports can be particularly useful in reducing the noise produced especially if the machine is small compared with a large flexible support or enclosure that can act as a sounding board and radiate the sound. Soft metal springs or elastomeric isolators are often used as isolators. They should be designed so that the natural frequency of the machine mass on its isolators is much less than the forcing frequency, if possible. Care should be taken that such a design condition does not produce excessive static deflection of the system that could interfere with the proper machine operation. Vibrating pipes and ducts can also be vibration-isolated from walls of buildings using pipe hangers or soft rubber isolators. Vibration breaks made of rubber or similar soft material can be built into elements such as walls in buildings or structural elements in vehicles or machine enclosures to prevent vibration being propagated throughout the building or other structure and being reradiated as noise (Crocker, 1997c).

Damping materials can also be effective at reducing noise when applied properly to structures if their vibration is resonant in nature. Damping materials that are viscous, applied with thicknesses two or three times that of the vibrating metal panel, are particularly effective. Constrained damping layers can be very effective even when the damping layer is relatively thin (Crocker, 1997c).

Figure 20.7.6 shows the reduction in the A-weighted sound level that can be expected using these passive noise control approaches discussed above. Often it is insufficient to use one approach, and greater, more-economic noise reduction can be achieved by using two or more approaches in conjunction.

## 20.8 Lighting Technology\*

*Barbara Atkinson, Andrea Denver, James E. McMahon, Leslie Shown, Robert Clear, and Craig B. Smith*

In this section, we describe the general categories of lamps, ballasts, and fixtures in use today. In addition, we briefly discuss several techniques for improving the energy-efficiency of lighting systems.

Because the purpose of a lamp is to produce light, and not just radiated power, there is no direct measure of lamp efficiency. Instead, a lamp is rated in terms of its **efficacy**, which is the ratio of the amount of light emitted (lumens) to the power (watts) drawn by the lamp. The unit used to express lamp efficacy is lumens per watt (LPW). The theoretical limit of efficacy is 683 LPW and would be produced by an ideal light source emitting monochromatic radiation with a wavelength of 555 nm. The lamps that are currently on the market produce from a few percent to almost 25% of the maximum possible efficacy.\*\* The efficacies of various light sources are depicted in [Figure 20.8.1](#). Lamps also differ in terms of their cost; size; color; lifetime; optical controllability; dimmability; **lumen maintenance**\*\*\*; reliability; simplicity and convenience in use, maintenance, and disposal; and environmental effects (e.g., emission of noise, radio interference, and ultraviolet (UV) light).

**FIGURE 20.8.1** Ranges of lamp efficacy. (Ballast losses are included for all discharge lamps.) (Compiled from U.S. DOE, 1993a; Morse, personal communication, 1994; and manufacturer's catalogs.)

\* The contents of this section have been abstracted from Chapters 10 (Electrical Energy Management in Buildings by Craig B. Smith) and 12B (Energy Efficient Lighting Technologies and Their Applications in the Commercial and Residential Sectors by Barbara Atkinson, Andrea Denver, James E. McMahon, Leslie Shown, and Robert Clear) published in the *CRC Handbook of Energy Efficiency*, Frank Kreith and Ronald E. West, Eds., 1997.

\*\* The efficacies of fluorescent lamp/ballast combinations reported in this section are based on data compiled by Oliver Morse from tests by the National Electrical Manufacturer's Association; all comparisons assume SP41 lamps. Efficacies of incandescent lamps are based on manufacturer catalogs. Efficacies of high-intensity discharge lamps are based on manufacturer catalogs and an assumed ballast factor of 0.95.

\*\*\* Over time, most lamps continue to draw the same amount of power but produce fewer lumens. The lumen maintenance of a lamp refers to the extent to which the lamp sustains its lumen output, and therefore efficacy, over time.

The color properties of a lamp are described by its color temperature and its color rendering index. **Color temperature**, expressed in degrees Kelvin (K), is a measure of the color appearance of the light of a lamp. The concept of color temperature is based on the fact that the emitted radiation spectrum of a blackbody radiator depends on temperature alone. The color temperature of a lamp is the temperature at which an ideal blackbody radiator would emit light that is closest in color to the light of the lamp. Lamps with low color temperatures (3000 K and below) emit “warm” white light that appears yellowish or reddish in color. Incandescent and warm-white fluorescent lamps have a low color temperature. Lamps with high color temperatures (3500 K and above) emit “cool” white light that appears bluish in color. Cool-white fluorescent lamps have a high color temperature.

The **color rendering index (CRI)** of a lamp is a measure of how surface colors appear when illuminated by the lamp compared to how they appear when illuminated by a reference source of the same color temperature. For color temperatures above 5000 K, the reference source is a standard daylight condition of the same color temperature; below 5000 K, the reference source is a blackbody radiator. The CRI of a lamp indicates the difference in the perceived color of objects viewed under the lamp and under the reference source. There are 14 differently colored test samples, 8 of which are used in the calculation of the general CRI index.

The CRI is measured on a scale that has a maximum value of 100 and is an average of the results for the 8 colors observed. A CRI of 100 indicates that there is no difference in perceived color for any of the test objects; a lower value indicates that there are differences. CRIs of 70 and above are generally considered to be good, while CRIs of 20 and below are considered to be quite poor. Most incandescent lamps have CRIs equal to or approaching 100. Low-pressure sodium lamps have the lowest CRI of any common lighting source (–44); their light is essentially monochromatic.

The optical controllability of a lamp describes the extent to which a user can direct the light of the lamp to the area where it is desired. Optical controllability depends on the size of the light-emitting area, which determines the beam spread of the light emitted. In addition, controllability depends on the fixture in which the lamp is used. Incandescent lamps emit light from a small filament area: they are almost point sources of light, and their optical controllability is excellent. In contrast, fluorescent lamps emit light from their entire phosphored area: their light is extremely diffuse, and their controllability is poor.

Because of the many different characteristics and the variety of applications by which a lamp can be judged, no one type of source dominates the lighting market. The types of lamps that are commonly available include incandescent, fluorescent, and high-intensity discharge (HID).

## Lamps

The *incandescent lamp* was invented independently by Thomas Edison in the United States and Joseph Swan in England in the late 1800s. An incandescent lamp produces light when electricity heats the lamp filament to the point of incandescence. In modern lamps the filament is made of tungsten. Because 90% or more of an incandescent's emissions are in the infrared (thermal) rather than the visible range of the electromagnetic spectrum, incandescent lamps are less efficacious than other types of lamps.

The two primary types of standard incandescent lamps are general service and reflector/PAR (parabolic aluminized reflector) lamps. General-service lamps (also known as A-lamps) are the pear-shaped, common household lamps. Reflector lamps, such as flood or spotlights, are generally used to illuminate outdoor areas or highlight indoor retail displays and artwork. They are also commonly used to improve the optical efficiency of downlights (discussed later). Downlights are used where controlling glare or hiding the light source is important.

In spite of the fact that they are the least efficacious lamps on the market today, standard incandescent lamps are used for almost all residential lighting in the U.S. and are also common in the commercial sector. They have excellent CRIs and a warm color; they are easily dimmed, inexpensive, small, lightweight, and can be used with inexpensive fixtures; and, in a properly designed fixture, they permit

excellent optical control. In addition, incandescent lamps make no annoying noises and contain essentially no toxic chemicals. They are simple to install, maintain, and dispose of.

Although they account for less than 3% of the incandescent market, *tungsten-halogen* and now *tungsten-halogen infrared-reflecting (HIR) lamps* are the incandescent lamps that offer the greatest opportunity for energy savings. Halogen lamps produce bright white light and have color temperatures and CRIs that are similar to, or slightly higher than, those of standard incandescent lamps. In addition, they have longer lives, can be much more compact, are slightly more efficacious, and have better lumen maintenance than standard incandescent lamps.

HIR lamps have been promoted to residential- and commercial-sector customers primarily as low-wattage reflector lamps. In general, HIR lamps have a small market share due to their high cost.

*Fluorescent lamps* came into general use in the 1950s. In a fluorescent lamp, gaseous mercury atoms within a phosphor-coated lamp tube are excited by an electric discharge. As the mercury atoms return to their ground state, ultraviolet radiation is emitted. This UV radiation excites the phosphor coating on the lamp tube and causes it to fluoresce, thus producing visible light. Fluorescent lamps are far more efficacious than incandescent lamps. The efficacy of a fluorescent lamp system depends upon the lamp length and diameter, the type of phosphor used to coat the lamp, the type of ballast used to drive the lamp, the number of lamps per ballast, the temperature of the lamp (which depends on the fixture and its environment), and a number of lesser factors.

Fluorescent lamps have long lives and fairly good lumen maintenance. While the standard-phosphor (cool-white (CW) and warm-white (WW)), lamps have CRIs of 50 to 60, the new rare earth phosphor lamps have CRIs of 70 to 80. The majority of lighting used in the commercial sector is fluorescent. Fluorescent lighting is also common in the industrial sector. The small amount of full-size fluorescent lighting in the residential sector is primarily found in kitchens, bathrooms, and garages. The most common fluorescent lamps are tubular and 4 ft (1.2 m) in length (see [Figure 20.8.2](#)).

**FIGURE 20.8.2** Typical full-size fluorescent lamp. (From Atkinson, B. et al., *Analysis of Federal Policy Options for Improving U.S. Lighting Energy Efficiency: Commercial and Residential Buildings*, Lawrence Berkeley National Laboratory, Berkeley, CA, 1992. With permission.)

Lamp tubes with a diameter of 1.5 in. (38 mm) are called T12s, and tubes that are 1 in. (26 mm) in diameter are called T8s. The 8 and 12 refer to the number of eighths of an inch in the diameter of the lamp tube. Lamp tubes are available in other diameters as well. Four-foot T12s are available in 32, 34, and 40 W. The specified wattage of a lamp refers to the power draw of the lamp alone even if lamp operation requires a ballast, as do all fluorescent and high-intensity discharge light sources. The ballast typically adds another 10 to 20% to the power draw, thus reducing system efficacy.

Even the smallest, least efficacious fluorescent lamps ( $\approx 30$  LPW for a 4-W lamp) are more efficacious than the most efficacious incandescent lamps ( $\approx 20$  LPW). Of the full-size fluorescent lamps available today, *rare earth phosphor lamps* are the most efficacious. In these lamps, rare earth phosphor compounds are used to coat the inside of the fluorescent lamp tube. Rare earth phosphor lamps are also called tri-phosphor lamps because they are made with a mixture of three rare earth phosphors that produce visible light of the wavelengths to which the red, green, and blue retinal sensors of the human eye are most sensitive. These lamps have improved color rendition as well as efficacy. Fluorescent lamps with

diameters of 1 in. (26 mm) and smaller use tri-phosphors almost exclusively. Rare earth coatings can also be used for lamps of larger diameter.

The most efficacious of the fluorescent lamps available today are T8 lamps operating with electronic ballasts. The efficacy of two 32-W T8 lamps operating with a single electronic ballast is about 90 LPW, approximately 30% more efficacious than the more standard lighting system consisting of two 40-W T12 lamps and a high-efficiency magnetic ballast. T12 lamps are also available with rare earth phosphors, and can attain over 80 LPW when used with a two-lamp electronic ballast. The characteristics and applications of 4-ft T8 lamps are summarized in [Table 20.8.1](#).

**TABLE 20.8.1 Characteristics and Applications of 4-ft Full-Size Fluorescent T8 Lamps**

Available wattages	32 W
Efficacy	For two T8s and a single electronic ballast, ≈90 LPW
Rated lifetime	Typically 12,000 to 20,000 hr
Color rendition	Typically 75–84
Color temperature	2800–7500 K
Lumen maintenance	Very good (light output typically declines by 10 to 12% over rated lamp life)
Optical controllability	Poor (very diffuse light but slightly better than a T12)
Typical uses	The majority of lighting used in the commercial sector is fluorescent. Fluorescent lighting is also used in the industrial sector. In the residential sector, full-size fluorescent lighting is used in some kitchens, bathrooms, and garages
Technologies for which these lamps are energy-efficient alternatives	These lamps are most often replacements for less-efficient fluorescents (T12s)
Notes	Some T8 lamps are now available with CRIs above 90, especially those with high color temperature; however, these lamps are less efficacious than lamps with lower CRIs

In spite of their much greater efficiency, fluorescent lamps have several disadvantages when compared to incandescent lamps. Fluorescent lamps can be dimmed, but only with special equipment that costs much more than the dimming controls used for incandescent lamps. Standard fluorescent lamps are much bigger than incandescent lamps of equivalent output and are much harder to control optically. In addition, fluorescent lamps contain trace amounts of mercury, a toxic metal, and emit more UV light than incandescent lamps. The ballast equipment that drives the lamps is sometimes noisy and may emit radio interference.

*Circular fluorescent lamps* in 20- to 40-W sizes have been available for many years, but have always had a fairly small market. Essentially, a circular lamp is a standard fluorescent lamp tube (as described earlier) that has been bent into a circle. Although they have a more compact geometry than a straight tube, circular lamps are still moderately large (16.5 to 41 cm in diameter).

*Compact fluorescent lamps* (CFLs), which are substantially smaller than standard fluorescent lamps, were introduced to the U.S. market in the early 1980s. In a CFL, the lamp tube is smaller in diameter and is bent into two to six sections (see [Figure 20.8.3](#)). CFLs have much higher power densities per phosphor area than standard fluorescents, and their design was therefore dependent on the development of rare earth phosphors, which could hold up much better than standard phosphors at high power loadings. CFLs are available as both screw-in replacements for incandescent lamps and as pin-base lamps for hard-wired fixtures. They may be operated with separate ballasts or purchased as integral lamp/ballast units.

*High-intensity discharge lamps* produce light by discharging an electrical arc through a mixture of gases. In contrast to fluorescent lamps, HID lamps use a compact “arc tube” in which both temperature and pressure are very high. Compared to a fluorescent lamp, the arc tube in an HID lamp is small enough to permit compact reflector designs with good light control. Consequently, HID lamps are both compact and powerful. There are currently three common types of HID lamps available: mercury vapor (MV), metal halide (MH), and high-pressure sodium (HPS).

**FIGURE 20.8.3** A variety of compact fluorescent and circular lamps: (a) twin-tube integral, (b and c) triple-tube integrals, (d) integral model with glare-reducing casing, (e) modular quad tube and ballast, and (f) modular circline and ballast. (Courtesy of Katherine Falk and *Home Energy* magazine, 1995.)

Because of their very high light levels, except in the smallest lamps, and their substantial cost (\$15 to 80 for lamps up to 400 W), HID lamps are most often used for exterior applications such as street lighting and commercial, industrial, and residential floodlighting (sports and security lighting). They are also used in large, high-ceilinged, interior spaces such as industrial facilities and warehouses, where good color is not typically a priority. Occasionally, HID lamps are used for indirect lighting in commercial offices. Interior residential applications are rare because of high cost, high light level, and the fact that HID lamps take several minutes to warm up to full light output. If there is a momentary power outage, the lamps must cool down before they will restrike. Some HID lamps are now available with dual arc tubes or parallel filaments. Dual arc tubes eliminate the restrike problem and a parallel filament gives instantaneous light output both initially and on restrike, but at a cost of a high initial power draw.

The *mercury vapor lamp* was the first HID lamp developed. Including ballast losses, the efficacies of MV lamps range from about 25 to 50 LPW. Uncoated lamps have a bluish tint and very poor color rendering (CRI  $\approx$  15). Phosphor-coated lamps emit more red, but are still bluish, and have a CRI of about 50. Because of their poor color rendition, these lamps are only used where good color is not a priority. Although MV lamps generally have rated lifetimes in excess of 24,000 hr, light output can diminish significantly after only 12,000 hr (Audin et al., 1994). Both metal halide and high-pressure sodium HIDD lamps have higher efficacies than mercury vapor lamps and have consequently replaced them in most markets.

Including ballast losses, *metal halide lamps* range in efficacy from 46 to 100 LPW. They produce a white to slightly bluish-white light and have CRIs ranging from 65 to 70. Lamp lifetimes range from only 3500 to 20,000 hr, depending on the type of MH lamp. Lower-wattage metal halides (particularly the 70-W and 100-W) are now available with CRIs of 65 to 75 and color temperatures of 3200 to 4200 K. Good lumen maintenance, longer life, reduced maintenance costs, and the fact that they blend more naturally with fluorescent sources have made MH lamps a very good replacement in the commercial sector for 300-W and 500-W PAR lamps. New fixtures utilizing these lamps, particularly 1-ft by 1-ft recessed lensed troffers (downlights), are becoming common in lobbies, shopping malls, and retail stores.

Including ballast losses, *high-pressure sodium lamps* have efficacies ranging from 50 LPW for the smallest lamps to 124 LPW for the largest lamps. Standard HPS lamps emit a yellow light and have very poor color rendition. Like MV lamps, HPS lamps are only used where good color is not a priority. The rated lifetimes of HPS lamps rival those of MV lamps and typically exceed 24,000 hr.

## Ballasts

Because both fluorescent and HID lamps (discharge lamps) have a low resistance to the flow of electric current once the discharge arc is struck, they require some type of device to limit current flow. A lamp ballast is an electrical device used to control the current provided to the lamp. In most discharge lamps, a ballast also provides the high voltage necessary to start the lamp. Older “preheat” fluorescent lamps require a separate starter, but these lamps are becoming increasingly uncommon. In many HID ballasts, the ignitor used for starting the lamp is a replaceable module.

The most common types of ballasts are magnetic core-coil and electronic high-frequency ballasts. A *magnetic core-coil ballast* uses a transformer with a magnetic core coiled in copper or aluminum wire to control the current provided to a lamp. Magnetic ballasts operate at an input frequency of 60 Hz and operate lamps at the same 60 Hz. An *electronic high-frequency ballast* uses electronic circuitry rather than magnetic components to control current. Electronic ballasts use standard 60 Hz power but operate lamps at a much higher frequency (20,000 to 60,000 Hz). Both magnetic and electronic ballasts are available for most fluorescent lamp types.

Of the ballasts that are currently available for fluorescent lamps, the most efficient options are the electronic ballast and the cathode cutout ballast. Because an electronic ballast is more efficient than a standard core-coil magnetic ballast in transforming the input power to lamp requirements, and because fluorescent lamps are more efficient when operated at frequencies of 20,000 Hz or more, a lamp/ballast system using an electronic rather than magnetic ballast is more efficacious. Where there are two lamps per ballast, electronic ballast systems are approximately 20% more efficacious than magnetic ballast systems; where there is only one lamp per ballast, electronic ballast systems are almost 40% more efficacious than magnetic ballast systems.

In addition, electronic ballasts eliminate flicker, weigh less than magnetic ballasts, and operate more quietly. Since electronic ballasts are packaged in “cans” that are the same size as magnetic ballasts, they can be placed in fixtures designed to be used with magnetic ballasts. Electronic ballasts are widely available, but their use is limited because of their high cost and some technological limitations for certain applications. Fluorescent electronic ballasts are available for standard commercial-sector applications.

The *cathode cut-out (hybrid) ballast* is a modified magnetic ballast. It uses an electronic circuit to remove the filament power after the discharge has been initiated for rapid-start lamps. Cathode cut-out ballasts use approximately 5 to 10% less energy than energy-efficient magnetic ballasts. Almost all ballasts used for HID lamps are magnetic, and a number of different types are available. The various types differ primarily in how well they tolerate voltage swings and, in the case of HPS lamps, the increased voltage required to operate the lamp as it ages.

## Lighting Fixtures

A lighting fixture is a housing for securing lamp(s) and ballast(s) and for controlling light distribution to a specific area. The function of the fixture is to distribute light to the desired area without causing glare or discomfort. The distribution of light is determined by the geometric design of the fixture as well as the material of which the reflector and/or lens is made. The more efficient a fixture is, the more light it emits from the lamp(s) within it. Although a lighting fixture is sometimes referred to as a luminaire, the term *luminaire* is most commonly used to refer to a complete lighting system including a lamp, ballast, and fixture.

Types of fluorescent lighting fixtures that are commonly used in the nonresidential sectors include recessed troffers, pendant-mounted indirect fixtures and indirect/direct fixtures, and surface-mounted commercial fixtures such as wraparound, strip, and industrial fixtures.

Most offices are equipped with *recessed troffers*, which are direct (downward) fixtures and emphasize horizontal surfaces. Many forms of optical control are possible with recessed luminaires. In the past, prismatic lenses were the preferred optical control because they offer high luminaire efficiency and uniform illuminance in the work space. Electronic offices have become increasingly common, however,

and the traditional direct lighting fixtures designed for typing and other horizontal tasks have become less useful because they tend to cause reflections on video display terminal (VDT) screens.

No lighting system reduces glare entirely, but some fixtures and/or components can reduce the amount of glare significantly. Because the glossy, vertical VDT screen can potentially reflect bright spots on the ceiling, and because VDT work is usually done with the head up, existing fixtures are sometimes replaced with indirect or direct/indirect fixtures, which produce light that is considered more visually comfortable. Most indirect lighting systems are suspended from the ceiling. They direct light toward the ceiling where the light is then reflected downward to provide a calm, diffuse light. Some people describe the indirect lighting as similar to the light on an overcast day, with no shadows or highlights. Generally, indirect lighting does not cause bright reflections on VDT screens. A *direct/indirect fixture* is suspended from the ceiling and provides direct light as well as indirect. These fixtures combine the high efficiency of direct lighting systems with the uniformity of light and lack of glare produced by indirect lighting systems.

A *wraparound fixture* has a prismatic lens that wraps around the bottom and sides of the lamp, and is always surface mounted rather than recessed. Wraparound fixtures are less expensive than other commercial fixtures and are typically used in areas where lighting control and distribution are not a priority. *Strip and industrial fixtures* are even less expensive and are typically used in places where light distribution is less important, such as large open areas (grocery stores, for example) and hallways. These are open fixtures in which the lamp is not hidden from view. The most common incandescent fixture in the nonresidential sector is the *downlight*, also known as a recessed can fixture. Fixtures designed for CFLs are available to replace downlight fixtures in areas where lighting control is less critical.

## Lighting Efficiency\*

There are seven techniques for improving the efficiency of lighting systems:

- Delamping
- Relamping
- Improved controls
- More efficient lamps and devices
- Task-oriented lighting
- Increased use of daylight
- Room color changes, lamp maintenance

The first two techniques and possibly the third are low in cost and may be considered operational changes. The last four items generally involve retrofit or new designs.

The first step in reviewing lighting electricity use is to perform a lighting survey. An inexpensive hand-held light meter can be used as a first approximation; however, distinction must be made between raw intensities (lux or footcandles) recorded in this way and *equivalent sphere illumination* (ESI) values.

Many variables can affect the “correct” lighting values for a particular task: task complexity, age of employee, glare, and so on. For reliable results, consult a lighting specialist or refer to the literature and publications of the Illuminating Engineering Society.

The lighting survey indicates those areas of the building where lighting is potentially inadequate or excessive. Deviations from adequate illumination levels can occur for several reasons: overdesign, building changes, change of occupancy, modified layout of equipment or personnel, more efficient lamps,

---

\* It should be noted that the “Lighting Efficiency” discussion was written by a different author than the earlier material in the chapter, and that there are some discrepancies between the lamp efficacy ranges reported in the two sections. These discrepancies are likely the result of the different data sources used to calculate efficacy ranges, the different time periods during which they were calculated, and different assumptions regarding which lamp types are most typical.

improper use of equipment, dirt buildup, and so on. Once the building manager has identified areas with potentially excessive illumination levels, he or she can apply one or more of the seven techniques listed earlier. Each of these will be described briefly.

Delamping refers to the removal of lamps to reduce illumination to acceptable levels. With incandescent lamps, bulbs are removed. With fluorescent or HID lamps, ballasts account for 10 to 20% of total energy use and should be disconnected after lamps are removed.

Fluorescent lamps often are installed in luminaires in groups of two or more lamps where it is impossible to remove only one lamp. In such cases an artificial load (called a “phantom tube”) can be installed in place of the lamp that has been removed.

Relamping refers to the replacement of existing lamps by lamps of lower wattage or increased efficiency. Low-wattage fluorescent tubes are available that require 15 to 20% less wattage (but produce

**TABLE 20.8.2 Typical Relamping Opportunities**

Change Office Lamps (2700 hr per year)		Energy Savings/Cost Savings		
		kWh	GJe	5¢ kWh
From	To	To save annually		
1 300-W incandescent	1 100-W mercury vapor	486	5.25	\$24.30
2 100-W incandescent	1 40-W fluorescent	400	4.32	20.00
7 150-W incandescent	1 150-W sodium vapor	2360	25.5	\$118.00
Change industrial lamps (3000 hr per year)				
1 300-W incandescent	2 40-W fluorescent	623	6.73	\$31.15
1 100-W incandescent	2 215-W fluorescent	1617	17.5	80.85
3 300-W incandescent	1 250-W sodium vapor	1806	19.5	90.30
Change store lamps (3300 hr per year)				
1 300-W incandescent	2 40-W fluorescent	685	7.40	\$34.25
1 200-W incandescent	1 100-W mercury vapor	264	2.85	13.20
2 200-W incandescent	1 175-W mercury vapor	670	7.24	33.50

10 to 15% less light). In some types of HID lamps, a more efficient lamp can be substituted directly. However, in most cases, ballasts must also be changed. Table 20.8.2 shows typical savings by relamping.

Improved controls permit lamps to be used only when and where needed. For example, certain office buildings have all lights for one floor on a single contactor. These lamps will be switched on at 6 A.M., before work begins, and are not turned off until 10 P.M., when maintenance personnel finish their cleanup duties. Energy usage can be cut by as much as 50% by installing individual switches for each office or work area, installing time clocks, installing occupancy sensors, using photocell controls, or instructing custodial crews to turn lights on as needed and turn them off when work is complete.

There is a great variation in the efficacy (a measure of light output per electricity input) of various lamps. Since incandescent lamps have the lowest efficacy, typically 8 to 20 LPW, wherever possible, fluorescent lamps should be substituted. This not only saves energy but also offers economic savings, since fluorescent lamps last 10 to 50 times longer. Fluorescent lamps have efficacies in the range of 30 to 90 LPW.

Compact fluorescent lamps are available as substitutes for a wide range of incandescent lamps. They range in wattage from 5 to 25 W with efficacies of 26 to 58 lm/W and will replace 25- to 100-W incandescent lamps. In addition to the energy savings, they have a 10,000-hr rated life and do not need to be replaced as often as incandescent lamps. Exit lights are good candidates for compact fluorescent lamps. Conversion kits are available to replace the incandescent lamps. Payback is rapid because of the lower energy use and lower maintenance cost, since these lamps are normally on 24 hr a day. There are also light-emitting diode exit lights that are very energy efficient.

Still greater improvements are possible with HID lamps such as mercury vapor, metal halide, and high-pressure sodium lamps. Although they are generally not suited to residential use (high light output and high capital cost) they are increasingly used in commercial buildings. They have efficacies in the range of 25 to 124 LPW.

Improved ballasts are another way of saving lighting energy. A comparison of the conventional magnetic ballast with improved ballasts shows the difference:

Type Lamp	2 Lamp 40 W	F40 T-12 CW	2 Lamp 32 W	F32 T-8
Ballast type	Standard magnetic	Energy-efficient magnetic	Electronic	Electronic
Input watts	96	88	73	64
Efficacy	60 lm/W	65 lm/W	78 lm/W	90 lm/W

The best performance comes from electronic ballasts, which operate at higher frequency. In addition to the lighting energy savings, there are additional savings from the reduced air-conditioning load due to less heat output from the ballasts. The environmental benefit for the electronic ballast described earlier, as estimated by the U.S. Environmental Protection Agency, is a reduction in CO<sub>2</sub> production of 150 lb/year, a reduction of 0.65 lb/year of SO<sub>2</sub>, and a reduction of 0.4 lb/year of NO<sub>x</sub>.

In certain types of buildings and operations, daylighting can be utilized to reduce (if not replace) electric lighting. Techniques include windows, an atrium, skylights, and so on. There are obvious limitations such as those imposed by the need for privacy, 24-hr operation, and building core locations with no access to natural light. Also, the use of light colors can substantially enhance illumination without modifying existing lamps.

An effective lamp maintenance program can also have important benefits. Light output gradually decreases over lamp lifetime. This should be considered in the initial design and when deciding on lamp replacement. Dirt can substantially reduce light output; simply cleaning lamps and luminaries more frequently can gain up to 5 to 10% greater illumination, permitting some lamps to be removed.

Reflectors are available to insert in fluorescent lamp fixtures. These direct and focus the light onto the work area, yielding a greater degree of illumination. Alternatively, in multiple lamp fixtures, one lamp can be removed and the reflector keeps the level of illumination at about 75% of the previous value.

## Defining Terms

**Ballast:** A lamp ballast is an electrical device used to control the current provided to the lamp. In most discharge lamps, a ballast also provides the high voltage necessary to start the lamp.

**Color Rendering Index (CRI):** A measure of how surface colors appear when illuminated by a lamp compared to how they appear when illuminated by a reference source of the same color temperature. For color temperature above 5000 K, the reference source is a standard daylight condition of the same color temperature; below 5000 K, the reference source is a blackbody radiator.

**Color temperature:** The color of a lamp's light is described by its color temperature, expressed in degrees Kelvin (K). The concept of color temperature is based on the fact that the emitted radiation spectrum of a blackbody radiator depends on temperature alone. The color temperature of a lamp is the temperature at which an ideal blackbody radiator would emit light that is the same color as the light of the lamp.

**Efficacy:** The ratio of the amount of light emitted (lumens) to the power (watts) drawn by a lamp. The unit used to express lamp efficacy is lumens per watt (LPW).

**Lumen maintenance:** Refers to the extent to which a lamp sustains its lumen output, and therefore efficacy, over time.

### Symbols and Units:

- $K$  = absolute temperature, degrees Kelvin
- deg  $C$  = temperature, degrees Celsius
- deg  $F$  = temperature, degrees Fahrenheit
- $\rho$  = density, kg/m<sup>3</sup>
- $c_p$  = specific heat capacity, kJ/kg·K
- $c_p/c_v$  = specific heat capacity ratio, dimensionless
- $\mu$  = viscosity, N·s/m<sup>2</sup> × 10<sup>6</sup> (For N·s/m<sup>2</sup> (= kg/m·s) multiply tabulated values by 10<sup>-6</sup>)
- $k$  = thermal conductivity, W/m·k × 10<sup>3</sup> (For W/m·K multiply tabulated values by 10<sup>-3</sup>)
- $Pr$  = Prandtl number, dimensionless
- $h$  = enthalpy, kJ/kg
- $V_s$  = sound velocity, m/s

**TABLE A.3 Psychrometric Table: Properties of Moist Air at 101 325 N/m<sup>2</sup>**

**Symbols and Units:**

- $P_s$  = pressure of water vapor at saturation, N/m<sup>2</sup>
- $W_s$  = humidity ratio at saturation, mass of water vapor associated with unit mass of dry air
- $V_a$  = specific volume of dry air, m<sup>3</sup>/kg
- $V_s$  = specific volume of saturated mixture, m<sup>3</sup>/kg dry air
- $h_a^a$  = specific enthalpy of dry air, kJ/kg
- $h_s$  = specific enthalpy of saturated mixture, kJ/kg dry air
- $s_s$  = specific entropy of saturated mixture, J/K·kg dry air

Note: The  $P_s$  column in this table gives the vapor pressure of pure water at temperature intervals of five degrees Celsius. For the latest data on vapor pressures at intervals of 0.1 deg C, from 0–100 deg C, see "Vapor Pressure Equation for Water", A. Wexler and L. Greenspan, *J. Res. Nat. Bur. Stand.*, 75A(3):213–229, May–June 1971.

\*For very low barometric pressures and high wet-bulb temperatures, the values of  $h_s$  in this table are somewhat low; for corrections see "ASHRAE Handbook of Fundamentals".

\*Computed from: Psychrometric Tables, in "ASHRAE Handbook of Fundamentals", American Society of Heating, Refrigerating and Air-Conditioning Engineers, 1972.

**TABLE A.4 Water Vapor at Low Pressures: Perfect Gas Behavior  $pv/T = R = 0.461\ 51\ \text{kJ/kg}\cdot\text{K}$**

**Symbols and Units:**

- $t$  = thermodynamic temperature, deg C
- $T$  = thermodynamic temperature, K
- $pv = RT$ , kJ/kg
- $u_o$  = specific internal energy at zero pressure, kJ/kg
- $h_o$  = specific enthalpy at zero pressure, kJ/kg
- $s_i$  = specific entropy of semiperfect vapor at 0.1 MN/m<sup>2</sup>, kJ/kg·K
- $\psi_i$  = specific Helmholtz free energy of semiperfect vapor at 0.1 MN/m<sup>2</sup>, kJ/kg
- $\psi_l$  = specific Helmholtz free energy of semiperfect vapor at 0.1 MN/m<sup>2</sup>, kJ/kg
- $\zeta_i$  = specific Gibbs free energy of semiperfect vapor at 0.1 MN/m<sup>2</sup>, kJ/kg
- $p_r$  = relative pressure, pressure of semiperfect vapor at zero entropy, TN/m<sup>2</sup>
- $v_r$  = relative specific volume, specific volume of semiperfect vapor at zero entropy, mm<sup>3</sup>/kg
- $c_{po}$  = specific heat capacity at constant pressure for zero pressure, kJ/kg·K
- $c_{vo}$  = specific heat capacity at constant volume for zero pressure, kJ/kg·K
- $k = c_{po}/c_{vo} = \text{isentropic exponent, } -(\partial \log p / \partial \log v)_s$

$t$	$T$	$pv$	$u_o$	$h_o$	$s_i$	$\psi_i$	$\zeta_i$	$p_r$	$v_r$	$c_{po}$	$c_{vo}$	$k$

TABLE A.6 Properties of Superheated Steam

**Symbols and Units:**

- $T$  = temperature, °C
- $T_{\text{sat}}$  = Saturation temperature, °C
- $v$  = Specific volume, m<sup>3</sup>/kg
- $u$  = internal energy, kJ/kg
- $h$  = enthalpy, kJ/kg
- $S$  = entropy, kJ/kg·K
- $p$  = pressure, bar and μPa

$T$ °C	$v$ m <sup>3</sup> /kg	$u$ kJ/kg	$h$ kJ/kg	$s$ kJ/kg · K	$v$ m <sup>3</sup> /kg	$u$ kJ/kg	$h$ kJ/kg	$s$ kJ/kg · K
<b><math>p = 0.06 \text{ bar} = 0.006 \text{ MPa}</math></b>				<b><math>p = 0.35 \text{ bar} = 0.035 \text{ MPa}</math></b>				
<b><math>(T_{\text{sat}} = 36.16^\circ\text{C})</math></b>				<b><math>(T_{\text{sat}} = 72.69^\circ\text{C})</math></b>

TABLE A.6 (continued) Properties of Superheated Steam

**Symbols and Units:**

- $T$  = temperature, °C
- $T_{\text{sat}}$  = Saturation temperature, °C
- $v$  = Specific volume, m<sup>3</sup>/kg
- $u$  = internal energy, kJ/kg
- $h$  = enthalpy, kJ/kg
- $S$  = entropy, kJ/kg·K
- $p$  = pressure, bar and μPa

$T$ °C	$v$ m <sup>3</sup> /kg	$u$ kJ/kg	$h$ kJ/kg	$s$ kJ/kg · K	$v$ m <sup>3</sup> /kg	$u$ kJ/kg	$h$ kJ/kg	$s$ kJ/kg · k

Long, "Thermochemistry for the Petrochemical Industry, Part II — Paraffinic Hydrocarbons, C<sub>1</sub>–C<sub>16</sub>" *Petroleum Refiner*, Vol. 28, No. 2, 1949, pp. 113–116.

## Appendix B. Properties of Liquids

**TABLE B.1 Properties of Liquid Water\***

### Symbols and Units:

$\rho$  = density, lbm/ft<sup>3</sup>. For g/cm<sup>3</sup> multiply by 0.016018. For kg/m<sup>3</sup> multiply by 16.018.

$c_p$  = specific heat, Btu/lbm-deg R = cal/g·K. For J/kg·K multiply by 4186.8

$\mu$  = viscosity. For lbf·sec/ft<sup>2</sup> = slugs/sec·ft, multiply by 10<sup>-7</sup>. For lbm·sec·ft multiply by 10<sup>-7</sup> and by 32.174. For g/sec·cm (poises) multiply by 10<sup>-7</sup> and by 478.80. For N·sec/m<sup>2</sup> multiply by 10<sup>-7</sup> and by 478.880.

$k$  = thermal conductivity, Btu/hr·ft·deg R. For W/m·K multiply by 1.7307.

Temp. °F	At 1 atm or 14.7 psia				At 1,000 psia				At 10,000 psia

† At 7,500 psia.

\* From: "1967 ASME Steam Tables", American Society of Mechanical Engineers, Tables 9, 10, and 11 and Figures 6, 7, 8, and 9.

The ASME compilation is a 330-page book of tables and charts, including a 2½ × 3½-ft Mollier chart. All values have been computed in accordance with the 1967 specifications of the International Formulation Committee (IFC) and are in conformity with the 1963 International Skeleton Tables. This standardization of tables began in 1921 and was extended through the International Conferences in London (1929), Berlin (1930), Washington (1934), Philadelphia (1954), London (1956), New York (1963) and Glasgow (1966). Based on these world-wide standard data, the 1967 ASME volume represents detailed computer output in both tabular and graphic form. Included are density and volume, enthalpy, entropy, specific heat, viscosity, thermal conductivity, Prandtl number, isentropic exponent, choking velocity, p-v product, etc., over the entire range (to 1500 psia 1500°F). English units are used, but all conversion factors are given.

TABLE B.2 Physical and Thermal Properties of Common Liquids

## Part a. SI Units

(At 1.0 Atm Pressure (0.101 325 MN/m<sup>2</sup>), 300 K, except as noted.)

Common name	Density, kg/m <sup>3</sup>	Specific heat, kJ/kg·K	Viscosity, N·s/m <sup>2</sup>	Thermal conductivity, W/m·K	Freezing point, K	Latent heat of fusion, kJ/kg	Boiling point, K	Latent heat of evapora- tion, kJ/kg	Coefficient of cubical expansion per K

Gelatin	1.27	79						

†Some values reported as low as 1.6

\*Based largely on: "Smithsonian Physical Tables", 9th rev. ed., W. E. Forsythe, Ed., The Smithsonian Institution, 1956, p. 292.

*Note:* In the case of substances with voids, such as paper or leather, the bulk density is indicated rather than the density of the solid portion. For density in kg/m<sup>3</sup>, multiply values in g/cm<sup>3</sup> by 1,000.

TABLE C.3 Specific Stiffness of Metals, Alloys, and Certain Non-Metallics\*

Specific stiffness is usually expressed as the modulus of elasticity (in tension) per unit weight-density, i.e.,  $E/\rho$ , in units of pounds and inches. While the stiffness of similar alloys varies considerably, there are definite ranges and groups to be recognized. Since the specific stiffness of steel is about 100 million, the values in the following table are also approximately the percentage stiffness, referred to steel.

<i>Material</i>	<i>Specific stiffness, millions</i>
Beryllium	650
Silicon carbide	600
Alumina ceramics	400
Mica	350
Titanium carbide cermet	250
Alumina cermet	200
Molybdenum and alloys; silica glass	130
Titanium and alloys; cobalt superalloys; soda-lime glass	110
Carbon and low-alloy steel; wrought iron	105
Stainless steel; nodular cast iron; magnesium and alloys; aluminum and alloys	100
Nickel and alloys; malleable iron	95
Iron silicon alloys (cast); iridium; vanadium	90
Monel alloys; tungsten	80
Gray cast iron; columbium alloys	70
Aluminum bronze; beryllium copper	65
Nickel silver; cupronickel; zirconium	55
Yellow brass; nickel cast iron; bronze; Muntz metal; antimony	50
Copper; red brass; tantalum	45
Silver and alloys; pewter; platinum and alloys; white gold	30
Tin; thorium	25
Gold	20
Tin-lead alloy	10
Lead	5

\*Compiled from several sources.

**TABLE C.4 Thermal Properties of Pure Metals—Metric Units**

TABLE C.5 Mechanical Properties of Metals and Alloys:\* Typical Composition, Properties, and Uses of Common Materials

For MN/m<sup>2</sup> multiply strength in thousands of psi by 6.895.

No.	Material	Nominal composition	Form and condition	Typical mechanical properties				Comments
				Yield strength (0.2% offset), 1000 lb/sq in.	Tensile strength, 1000 lb/sq in.	Elongation, in 2 in., %	Hardness, Brinell	
<b>FERROUS ALLOYS</b>								
Ferrous alloys comprise the largest volume of metal alloys used in engineering. The actual range of mechanical properties in any particular grade of alloy steel depends on the particular history and heat treatment. The steels listed in this table are intended to give some idea of the range of properties readily obtainable. Many hundreds of steels are available. Cost is frequently an important criterion in the choice of material; in general the greater the percentage of alloying elements present in the alloy, the greater will be the cost.								
1	<i>IRON</i> Ingot iron (Included for comparison)	Fe 99.9	Hot-rolled Annealed	29 19	45 38	26 45	90 67	
2	<i>PLAIN CARBON STEELS</i> AISI-SAE 1020	C 0.20 Mn 0.45 Si 0.25 Fe bal.	Hot-rolled Hardened (water-quenched, 1000°F-tempered)	30 62	55 90	25 25	111 179	Bolts, crankshafts, gears, connecting rods; easily weldable
3	AISI 1025	C 0.25 Fe bal. Mn 0.45	Bar stock Hot-rolled Cold-drawn	32 54	58 64	25 15	116 126

<b>CAST IRONS AND CAST STEELS</b>									
These alloys are used where large and/or intricate-shaped articles are required or where over-all dimensional tolerances are not critical. Thus the article can be produced with the fabrication and machining costs held to a minimum. Except for a few heat-treatable cast steels, this class of alloys does not demonstrate high-strength qualities.

**SUPER ALLOYS**

The advent of engineering applications requiring high temperature and high strength, as in jet engines and rocket motors, has led to the development of a range of alloys collectively called super alloys. These alloys require excellent resistance to oxidation together with strength at high temperatures, typically 1800°F in existing engines. These alloys are continually being modified to develop better specific properties, and therefore entries in this group of alloys should be considered "fluid". Both wrought and casting-type alloys are represented. As the high temperature properties of cast materials improve, these alloys become more attractive, since great dimensional precision is now attainable in investment castings.

**ALUMINUM ALLOYS**

Although the strength of aluminum alloys is in general less than that attainable in ferrous alloys or copper-base alloys, their major advantage lies in their high strength-to-weight ratio due to the low density of aluminum. Aluminum alloys have good corrosion resistance for most applications except in alkaline solutions.

43	3003 ASTM B221	Cu 0.12	Al bal.	Annealed-O	6	16	40	28	Good formability, weldable, medium strength; chemical equipment

## COPPER ALLOYS

Because of their corrosion resistance and the fact that copper alloys have been used for many thousands of years, the number of copper alloys available is second only to the ferrous alloys. In general copper alloys do not have the high-strength qualities of the ferrous alloys, while their density is comparable. The cost per strength-weight ratio is high; however, they have the advantage of ease of joining by soldering, which is not shared by other metals that have reasonable corrosion resistance.

## TIN AND LEAD-BASE ALLOYS

Major uses for these alloys are as "white"-metal bearing alloys, extruded cable sheathing, and solders. Tin forms the basis of pewter used for culinary applications.

72	Lead-base Babbitt ASTM B23, alloy 19	Pb 85.0 Sb 10.0 Cu 0.5	Sn 5.0 As 0.6	Chill cast	—	10	5	19	Bearings, light loads and low speeds
73	Arsenical-lead Babbitt ASTM B23, alloy 15	Pb 83.0 Sb 16.0 Cu 0.6	Sn 1.0 As 1.1	Chill cast	—	10.3	2	20	Bearings, high loads and speeds, diesel engines, steel mills
74	Chemical lead	Pb 99.9 Bi 0.005 max	Cu 0.06	Rolled 95%	1.9	2.5	50	5	
75	Antimonial lead (hard lead)	Pb 94.0	Sb 6.0	Chill cast Rolled 95%	— —	6.8 4.1	22 47	(500 kg) 9	Good corrosion resistance and strength
76	Calcium lead	Pb 99.9 Cu 0.10	Ca 0.025	Extruded and aged	—	4.5	25	—	Cable sheathing, creep-resistant pipe
77	Tin Babbitt alloy ASTM B23-61, grade 1	Sb 4.5 Cu 4.5	Sn bal.	Chill cast	—	9.3	2	17	General bearings and die casting
78	Tin die-casting alloy ASTM B102-52	Sb 13.0 Cu 5.0	Sn bal.	Die-cast	—	10	1	29	Die-casting alloy

**TABLE C.5 (continued) Mechanical Properties of Metals and Alloys:\* Typical Composition, Properties, and Uses of Common Materials**

No.	Material	Nominal composition		Form and condition	Typical mechanical properties				Comments
					Yield strength (0.2% offset), 1000 lb/sq in.	Tensile strength, 1000 lb/sq in.	Elongation, in 2 in., %	Hardness, Brinell	
79	Pewter	Sn 91.0 Cu 2.0	Sb 7.0	Rolled sheet, annealed	—	8.6	40	9.5	Ornamental and household items
80	Solder 50-50	Sn 50.0	Pb 50.0	Cast	4.8	6.1	60	14	General-purpose solder
81	Solder	Sn 20.0	Pb 80.0	Cast	3.6	5.8	16	11	Coating and joining, filling seams on automobile bodies

**MAGNESIUM ALLOYS**

Because of their low density these alloys are attractive for use where weight is at a premium. The major drawback to the use of these alloys is their ability to ignite in air (this can be a problem in machining); they are also costly. Magnesium alloys are used in both the wrought and die-cast forms, the latter being the most frequently used form.

82	Magnesium alloy AZ31B	Zn 1.0	Mn 0.20	Rolled-plate (strain-hardened, then partially annealed)	24	37	18	—	Structural applications of medium strength
		Al 3.0	min Mg bal.		Rolled-sheet (strain-hardened, then partially annealed)	32	42	15	
				Annealed	22	37	21	56	
				Extruded	28	38	14	—	
83	Magnesium alloy AZ80A	Zn 0.5	Mn 0.15	Extruded	36	49	11	60	General extruded and forged products
		Al 8.5	min Mg bal.	Extruded (age-hardened)	39	53	6	82	
				Forged (age-hardened)	34	50	6	72	
84	Magnesium alloy AZ92A	Zn 2.0	Mn 0.10	Sand-cast (as cast)	14	24	6	50	Pressure-tight sand and permanent mold castings; high UTS and good yield strength
		Al 9.0	min Mg bal.	Sand-cast (solution heat-treated)	14	40	12	55	
				Sand-cast (solution heat-treated and aged)	19	40	5	83	
				Sand-cast (age-hardened)	16	30	18	—

					38	51			
					40	60	10-40		
					60	90			

**NICKEL ALLOYS**

Nickel and its alloys are expensive and used mainly either for their high-corrosion resistance in many environments or for high-temperature and strength applications. (See Super Alloys, above.)

88	Nickel (cast)	Ni 95.6	Cu 0.5	As cast	25	57	22	110	Good corrosion-resistance applications
		Fe 0.5	Mn 0.8						
		Si 1.5	C 0.8

		Mn 0.25	Si 0.55	Spring	—	175	5	320	
		S 0.005	Al 4.50	Spring, age-hardened	—	205	10	370	
		Cu 0.05							
		Ti 0.45							

**TABLE C.5 (continued) Mechanical Properties of Metals and Alloys:\* Typical Composition, Properties, and Uses of Common Materials**

No.	Material	Nominal composition		Form and condition	Typical mechanical properties				Comments
					Yield strength (0.2% offset), 1000 lb/sq in.	Tensile strength, 1000 lb/sq in.	Elongation, in 2 in., %	Hardness, Brinell	
92	Cupronickel 55-45 (Constantan)	Cu 55.0	Ni 45.0	Annealed Cold-drawn Cold-rolled	30 50 65	60 65 85	45 30 20	— — —	Electrical-resistance wire; low temperature coefficient, high resistivity
93	Nichrome	Ni 80.0	Cr 20.0						Heating elements for furnaces
94	"S" Monel	Ni 60.0 Fe 2.50 max Si 4.0	Cu 29.0 Mn 1.5 max Al 0.5 max	Sand-casting	80-115	110-145	2	270-350	High-strength casting alloy; good bearing properties for valve seats

**TITANIUM ALLOYS**

The main application for these alloys is in the aerospace industry. Because of the low density and high strength of titanium alloys, they present excellent strength-to-weight ratios.

95	Commercial titanium ASTM B265-58T	Ti 99.4		Annealed at 1100 to 1350°F (593 to 732°C)	70	80	20	—	Moderate strength, excellent fabricability; chemical industry pipes
96	Titanium alloy ASTM B265-58T-5 Ti-6 Al-4V			Water-quenched from 1750°F (954°C); aged at 1000°F (538°C) for 2 hr	160	170	13	—	High-temperature strength needed in gas-turbine compressor blades
97	Titanium alloy Ti-4 Al-4Mn			Water-quenched from 1450°F (788°C); aged at 900°F (482°C) for 8 hr	170	185	13	—	Aircraft forgings and compressor parts
98	Ti-Mn alloy ASTM B265-58T-7	Fe 0.5 Mn 7.0-8.0	Ti bal.	Sheet	140	150	18	—	Good formability, moderate high-temperature strength; aircraft skin

**ZINC ALLOYS**

A major use for these alloys is for low-cost die-cast products, such as household fixtures, automotive parts, and trim.

99	Zinc ASTM B69	Cd 0.35 Pb 0.08	Zn bal.	Hot-rolled	—	19.5	65	38	Battery cans, grommets, lithographer's sheet
----	------------------	--------------------	---------	------------	---	------	----	----	---

TABLE C.5 (continued) Mechanical Properties of Metals and Alloys:\* Typical Composition, Properties, and Uses of Common Materials

No.	Material	Nominal composition	Form and condition	Typical mechanical properties				Comments

100	Zilloy-15	Cu 1.00 Mg 0.010	Zn bal. Hot-rolled Cold-rolled	— —	29 36	20 25	61 80	Corrugated roofs, articles with maximum stiffness
101	Zilloy-40	Cu 1.00	Zn bal. Hot-rolled Cold-rolled	— —	24 31	50 40	52 60	Weatherstrip, spun articles
102	Zamac-5 ASTM 25	Zn (99.99% pure re- mainder) Mg 0.03- 0.08	Al 3.5- 4.3 Cu 0.75- 1.25 Die-cast	—	47.6	7	91	Die casting for automobile parts, padlocks; used also for die material

## ZIRCONIUM ALLOYS

These alloys have good corrosion resistance but are easily oxidized at elevated temperatures in air. The major application is for use in nuclear reactors.

103	Zirconium, commercial	O <sub>2</sub> 0.07 Hf 1.90	C 0.15 Zr bal.	Annealed	40	65	27	B80 (Rockwell)	Nuclear power-reactor cores at elevated temperatures

**TABLE C.7 Composition and Melting Points of Binary Eutectic Alloys:\* Binary Alloys and Solid Solutions of Metallic Components**

This table represents most of the common binary combinations of metals. For many pairs no eutectic exists; for many others the information is uncertain or unavailable. In a fair number of cases, there is complete mutual solubility in all proportions; hence, there is a smooth temperature vs. composition curve, with no point of inflection from the melting point of one constituent to that of the other. For purposes of comparison, all values must be considered approximate in view of the experimental difficulties and the many sources of data.

Those pairs for which the liquidus curve exhibits more than one cusp are designated by a superscript *a*. In a few cases the cusp selected for this table does not represent the lowest possible melting point for the binary mixture.

\*The data in this table are compiled from various sources—hence the variations in the melting point of the metals as shown in this column.

\*\*Based largely on: "Smithsonian Physical Tables", 9th rev. ed., W.E. Forsythe, Ed., The Smithsonian Institution, 1956.

TABLE C.9 Trade Names, Composition, and Manufacturers of Various Plastics

Trade name	Composition	Manufacturer	Trade name	Composition	Manufacturer
Abson	Acrylonitrile-butadiene, ABS polymers	B. F. Goodrich Chemical Co.	Forticel	Cellulose propionate sheet films, molding powders	Celanese Plastics Co.
Alathon	Polyethylene resins	E. I. du Pont de Nemours & Co., Inc.	Fortiflex	Polyethylene resins	Celanese Plastics Co.
Alkor	Furan resin cement	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.	Fosta-Tuf-Flex	Polystyrene, high-impact	Foster-Grant, Inc.
Amres	Phenolics, urea, and melamine resins	American Marietta Co., Pacific Resins & Chemicals, Inc.	Furnane	Furanes	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Araldite	Epoxy resins	CIBA Products Co., Div. CIBA Corp.	GenEpoxy	Epoxy resins for adhesives, coatings, etc.	General Mills, Inc., Chemical Div.
Atlac	Polyester resins	Atlas Chemical Industries, Inc.	Genetron	Fluorinated hydrocarbons, monomers, and polymers	Allied Chemical Corp., General Chemical Div.
Bakelite	Acrylics, epoxies, phenolics, polyethylenes, copolymers	Union Carbide Corp., Chemicals and Plastics Div.	Geon	Polyvinyl chloride materials	B. F. Goodrich Chemical Co.
Bavick-11	Methylmethacrylate and methylstyrene copolymer	J. T. Baker Chemical Co.	Grex	High-density polyethylenes	Allied Chemical Corp., Plastics Div.
Boltaflex	Supported and unsupported flexible vinyl sheeting	The General Tire & Rubber Co.	Halon	Fluorohalocarbon resins	Allied Chemical Corp.
Boltaron	Rigid polyvinyl chloride sheet	The General Tire & Rubber Co., Chemical & Plastics Div.	Hetron	Fire-retardant polyester resin	Hooker Chemical Corp., Durez Plastics Div.
Butacite	Polyvinyl butyral resins	E. I. du Pont de Nemours & Co., Inc.	Isothane	Polyurethane foam, ester, and ether	Bernel Foam Products Co., Inc.
Conolite	Polyester resins and laminates	Shellmar-Betner, Div. Continental Can Co. Woodall Industries, Inc., Conolite Div.	Kel-F	Chlorotrifluoroethylene, molding resins, and dispersions	3M Company
Corvel	Epoxies, vinyls Fusion-bond finishes	The Polymer Corp., Export-Polypenco Div.	Kralac	High-styrene resins, styrene-butadiene copolymers	Uniroyal Chemical, Div. of Uniroyal Inc.
Cumar	Paracoumarone-indene resins	Allied Chemical Corp., Plastics Div.	Kralastic	ABS polymers, copolymers	Uniroyal Chemical, Div. of Uniroyal Inc.
Cycolac	ABS polymers, acrylonitrile-butadiene-styrene copolymers	Marbon Chemical Div., Borg-Warner Corporation	Kynar	Polyvinylidene fluoride	Pennsalt Chemical Corp.
Dacovin	Polyvinyl chlorides	Diamond Shamrock Corp.	Lexan	Polycarbonate resin, film, and sheet	General Electric Company, Plastics Dept.
Dapon	Diallyl phthalate resins	FMC Corp., Organic Div.	Lucite	Acrylic resin and syrup	E. I. du Pont de Nemours & Co., Inc.
Delrin	Acetal resin and pipe	E. I. du Pont de Nemours & Co., Inc.	Lustran	ABS polymers	Monsanto Co.
Dylan	Polyethylene	Sinclair-Koppers Co.	Lustrex	Styrene molding and extrusion resins	Monsanto Co.
Dylene	Polystyrene	Sinclair-Koppers Co.	Lytron	Styrene molding and extrusion resins	Monsanto Co.
Dylite	Expandable polystyrene	Sinclair-Koppers Co.	Madurit	Melamine resins and compounds	Cassella Farbwerke Mainkur, A.G.
Epi-Rez	Epoxy resins	Celanese Resin Div., Celanese Coatings Co.	Maraglas	Epoxy-casting resin	The Marblette Corporation, Div. of Allied Products
Epolene	Low molecular-weight polyethylene resins	Eastman Chemical Products, Inc., Sub. Eastman Kodak Company	Marlex	Polyethylenes, polypropylenes, copolymers	Phillips Petroleum Co.
Epoxical	Epoxy resins	United States Gypsum Co.	Marvinol	Vinyl chloride resins and compounds	Uniroyal Chemical, Div. of Uniroyal Inc.
Epon	Epoxy resins and curing agents	The Shell Chemical Company, Plastics and Resins Div.	Merlon	Polycarbonate resins	Mobay Chemical Co.
Escon	Polypropylene resins	Enjay Chemical Co., Div. Humble Oil & Refining Company	Micarta	Melamines, phenolics, polyesters	Westinghouse Electric Co., Industrial Micarta Div.
Estane	Polyurethane materials	B. F. Goodrich Chemical Company	Microthene	Polyethylenes, polyolefins	U.S. Industrial Chemicals Co.
Fluorogreen	Teflon with glass and ceramic fibers, fluorocarbons	John L. Dore Co.	Multrathane Nopcofoam	Urethane elastomers Polyurethane plastics	Mobay Chemical Company Nopco Chemical Co., Plastics Div.
Fluororay	Ceramic-filled fluorocarbons	Raybestos-Manhattan, Inc., Plastic Products Div.	Novodur	Polyacrylonitrile-butadiene-styrene	Farbenfabriken Bayer, A. G.
Formica	Melamines	Formica Corp. of American Cyanamid	Opalon	Vinyl chloride resins and compounds	Monsanto Co.
			Paraplex	Polyester resins, acrylic-modified polyester resins	Rohm & Haas Company

**TABLE C.9 (continued) Trade Names, Composition, and Manufacturers of Various Plastics**

<i>Trade name</i>	<i>Composition</i>	<i>Manufacturer</i>	<i>Trade name</i>	<i>Composition</i>	<i>Manufacturer</i>
Permelite	Melamines	Melamine Plastics, Inc., Div. of Fiberlite Corp.	Super Dylan	Polyethylene	Sinclair-Koppers Co.
Petrothene	Polyethylene resins, polypropylene resins	U.S. Industrial Chemicals Co.	Supreme	Polyethylenes	Johns-Manville Company
Piccoflex	Styrene-copolymer resins	Pennsylvania Industrial Chemical Corp.	Sylplast	Urea-formaldehyde compounds	FMC Corp., Organic Chemicals Div.
Piccolastic	Styrene-polymer resins	Pennsylvania Industrial Chemical Corp.	Teflon	Fluorocarbon resins	E. I. du Pont de Nemours & Co., Inc.
Plaskon	Nylons, melamines, phenolics, polyesters	Allied Chemical Corp.	Tenite	Cellulose acetate, cellulose-acetate- polyethylene, poly- propylenes, urethane elastomers, copolymers	Eastman Chemical Products, Inc., Sub. Eastman Kodak Co.
Pleogen	Alkyds, polyesters, copolymers	Mol-Rez Div., American Petrochemical Corp.	Tetran	Fluorocarbons	Pennsalt Chemicals Corp.
Plexiglas	Acrylics	Rohm & Haas Company	Texin	Urethane elastomers	Mobay Chemical Company
Pliovic	Polyvinyl chlorides	The Goodyear Tire & Rubber Co., Chemical Div.	Thiomont	Polyisoprenes	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Plyophen	Phenolic resins	Reichhold Chemicals, Inc.	Ultrapas	Melamine resins	Dynamit Nobel, A. G.
Poly-Eth	Polyethylene resins	Gulf Oil Corp., U.S. Div. of Gulf Oil Corp.	Ultrathene	Ethylene-vinyl acetates	U.S. Industrial Chemicals Co.
Polylite	Polyester resins	Reichhold Chemicals, Inc.	Ultron	Polyvinyl chlorides	Monsanto Co.
Polypenco	Acrylics, chlorinated polyethers, fluoro- carbons, nylons, polycarbonates	Polymer Corp.	Vibrathane	Urethane elastomers	Uniroyal Chemical, Div. of Uniroyal Inc.
Resimene	Urea and melamine resins	Monsanto Co.	Vibrin	Polyester resins	Uniroyal Chemical, Div. of Uniroyal Inc.
Resinox	Phenolic resins and compounds	Monsanto Co.	Vitel	Polyesters	The Goodyear Tire & Rubber Co., Chemical Div.
Rhonite	Urea resins	Rohm & Haas Company	Viton	Synthetic rubbers	E. I. du Pont de Nemours & Co., Inc.
Roylar	Polyurethanes	Uniroyal Chemical, Div. of Uniroyal Inc.	Vitroplast	Polyester cements	Atlas Minerals & Chemicals Div., The Electric Storage Battery Co.
Ryertex	Laminated phenolics and rigid polyvinyl chloride extrusions	Joseph T. Ryerson & Son, Inc., Industrial Plastics and Bearings Sales Div.	Vyron	Polyvinyl chlorides	Industrial Vinyls, Inc.

TABLE C.10 Properties of Commercial Nylon Resins\*

Property	Type 6/6	Type 6	Type 6/10	Type 11	Glass-reinforced Type 6/6, 40%	MoS <sub>2</sub> -filled, 2%	Direct polymerized, castable
<b>Mechanical</b>

**Notes:**

Most nylon resins listed in this table are used for injection molding, and test values are determined from standard injection-molded specimens. In these cases a single typical value is listed. Exceptions are MoS<sub>2</sub>-filled nylon and direct-polymerized (castable) nylon, which are sold principally in semifinished stock shapes. Ranges of values listed are based on tests on various forms and sizes produced under varying processing conditions.

Because single values apply only to standard molded specimens, and properties vary in finished parts of different sizes and forms produced by various processes, these values should be used for comparison and preliminary design considerations only. For final design purposes the manufacturer should be consulted for test experience with the form being considered. Listed values should not be used for specification purposes.

For Conversion factors see Table C.10.

**TABLE C.11 Properties of Silicate Glasses\***

Most of the commercially produced glass is for windows, bottles, and inexpensive containers; it is a soda-lime-silica glass of fairly uniform composition, similar to glass No. 0080 in the table below and in Table 1-93. The following tables on glasses (Tables 1-92 through 1-103) deal largely with that one-tenth of the glass output for which special properties are required. All data are subject to normal manufacturing variations.

Silica glass is inherently high in viscosity and melting point. These are reduced by fluxes such as Na<sub>2</sub>O, K<sub>2</sub>O, and B<sub>2</sub>O<sub>3</sub>. Soda and potash glasses have a high expansion coefficient (column 7), while that of fused silica is very low. Because the borosilicate glasses are intermediate, and their thermal shock resistance is high (e.g., Corning Code 7740 glass), they are widely used for laboratory and kitchen glassware. Aluminosilicate glasses are hard, heat-resisting, and of high chemical durability. Glass hardness (indentation) correlates closely with the elastic modulus (column 14). Lead oxide is also used as flux, with a result of reduced softening point and high refractive index: hence its uses for optical glass and art glass.

Sealing of glass with metal calls for close control of the coefficient of expansion (column 7 and Figure 1-99).

**EXPLANATION OF COLUMNS:**

**Column 5:**

- |              |                   |                  |
|--------------|-------------------|------------------|
| B—blown ware | P—pressed ware    | S—plate glass    |
| M—multiform  | R—rolled sheet    | T—tubing and rod |
| U—panels     | LC—large castings |                  |

**Column 6:**

<sup>2</sup>Since weathering is determined primarily by clouding, which changes transmission, a rating for the opal glasses is omitted.

<sup>3</sup>These borosilicate glasses may rate differently if subjected to excessive heat treatment.

**Column 8:**

Normal service: No breakage from excessive thermal shock is assumed.

Extreme limits: Glass will be very vulnerable to thermal shock. Recommendations in this range are based on mechanical stability considerations only. Tests should be made before adopting final designs. These data are approximate only.

**Column 9:**

Based on plunging sample into cold water after oven heating. Resistance of 100°C means no breakage if heated to 110°C and plunged into water at 10°C. Tempered samples have over twice the resistance of annealed glass. These data are approximate only.

**Column 10:**

<sup>4</sup>These data are estimated.

Resistance in °C is the temperature differential between the two surfaces of a tube or a constrained plate that will cause a tensile stress of 1000 psi on the cooler surface.

**Column 11:**

Viscosity is given in poises. At the strain point the stresses are significantly reduced in a matter of hours, while at the annealing point there is adequate stress reduction in minutes.

**Column 12:**

Data show relative resistance to sandblasting.

**Column 15:**

Data at 25°C are extrapolated from high temperature readings and are approximate only.

†Viscosities at these four temperatures are approximately as follows: 10<sup>14.5</sup> poises at the strain point, 10<sup>13</sup> poises at the annealing point, 10<sup>7.8</sup> poises at the softening point, at 10<sup>4</sup> poises at the working point.

TABLE C.12 Properties of Window Glass\*: Transmittance of Sheet and Plate Glass

Type or tint	Nominal thickness, in.	Weight, lb/ft <sup>2</sup>	Transmittance	
			Total visible daylight, %	Direct 90° solar energy, %
Sheet	$\frac{1}{16}$	0.81	91	89
Sheet	$\frac{5}{64}$	1.00	91	88
Sheet	$\frac{3}{32}$	1.22	90	87
Sheet	$\frac{1}{8}$	1.64	90	86
Sheet	$\frac{3}{16}$	2.47	89	84
Sheet	$\frac{7}{32}$	2.85	89	82
Plate or float	$\frac{1}{8}$	1.64	90	86
Plate or float	$\frac{1}{4}$	3.28	88	79
Plate or float	$\frac{5}{16}$	4.09	88	77
Plate or float	$\frac{3}{8}$	4.91	87	74
Plate or float	$\frac{1}{2}$	6.55	86	70
Plate or float	$\frac{5}{8}$	8.18	85	65
Plate or float	$\frac{3}{4}$	9.83	83	60
Plate or float	$\frac{7}{8}$	11.45	81	55
Plate or float	1	13.13	79	49
Gray <sup>a</sup>	$\frac{1}{4}$	3.28	43	46
Bronze <sup>a</sup>	$\frac{1}{4}$	3.28	49	45
Green <sup>a</sup>	$\frac{1}{4}$	3.28	75	46
Double <sup>b</sup>	$\frac{1}{4}$ each	6.56	78	—

Note: Many types of glass are available, including tempered heat-strengthened glass, laminated shatter-proof glass, conductive-coated glass, reflective-coated glass. Several double-pane combinations are offered.

Direct 90° transmittance of solar ultraviolet radiation through non-tinted window glass is about 85 percent as high as the values for total solar energy transmittance. Ultraviolet transmittance of gray or bronze glass is lower.

Infrared transmittance is considerably lower than visual transmittance. This is significant in view of the large percentage of infrared radiation from most sources.

Visible reflectance of untinted glass is about 8 percent.

Approximate shading coefficients, ASHRAE,  $\frac{1}{4}$ -in. glass only: clear, 0.93; gray, 0.67; bronze, 0.65; green, 0.67.

Overall heat transfer coefficient of window area (air to air) is usually assumed to be 1.0 Btu/ft<sup>2</sup> hr, but it is lower if there is no wind.

For other data on shading coefficients, spectral transmittance, coated glass, special glasses, etc., see Tables 1-91, 2-19, and 7-19.

<sup>a</sup>Transmittance of tinted glass depends on depth of tint.

<sup>b</sup>Two  $\frac{1}{4}$ -in. panes with  $\frac{1}{2}$ -in. air space, sealed.

\*Tables compiled from several sources.

	Green	Dry			lb/cu ft, green	lb/cu ft, air-dry 12%	lb/1000 board ft, air-dry 12%
Alder, red	0.37	0.41	Low shrinkage; moderate in strength, shock resistance, hardness, and weight†	Furniture; sash; doors; millwork	46	28	2330
Ash, black	0.45	0.49	Light in weight†	Cabinets; veneer; cooper- age, containers	52	34	2830
Ash, Oregon	0.50	0.55	Similar to but lighter than white ash†	Similar to white ash	46	38	3160
Ash, white	0.54	0.58	Heavy; hard; stiff; strong; high shock resistance†	Handles; ladder rungs; baseball bats; farm im- plements; car parts	48	41	3420
Bald cypress (Southern cypress)			Moderate in strength, weight, hardness, and shrinkage**	Building construction; beams; posts; ties; tanks; ships; paneling	51	32	2670
Beech, American	0.56	0.64	Heavy; high strength, shock resistance, and shrinkage; uniform texture†	Flooring; furniture; handles; kitchenwear; ties (treated)	54	45	3750
Birch	0.57	0.63	Heavy; high strength, shock resistance, and shrinkage; uniform texture†	Interior finish; dowels; ties (treated); veneer; musical instruments	57	44	3670
Cottonwood	0.37	0.40	Uniform texture; does not split readily; moderate in weight, strength, hard- ness, and shrinkage	Crates; trunks; car parts; farm implements	49	28	2330
Douglas fir	0.41	0.44	Moderate in strength, weight, shock resistance, and shrinkage†	Building and construction; poles; veneer; plywood; ships; furniture; boxes	38	34	2830
Elm	0.57	0.63	Moderate in strength, weight, and hardness; high in shock resistance and shrinkage; good in bending†	Cooperage; baskets; crates; veneer; vehicle parts	54	34	2920
Hemlock, Eastern	0.38	0.40	Moderate in weight, strength, and hardness†	Building and construction; boxes	50	28	2330
Hemlock, Western	0.38	0.42	Moderate in weight, strength, and hardness†	Sash; doors; posts; piles; building and construction	41	29	2420
Hickory, true	0.65	0.73	High toughness, hardness, shock resistance, strength, and shrinkage†	Dowels; spokes; poles; shafts; gymnasium equip- ment	63	51	4250
Incense cedar	0.35		Uniform texture; easy to season; low shrinkage; shock resistance, weight, and stiffness**	Lumber; fence posts; ties; poles; shingles	45		
Larch, Western	0.48	0.52	Moderate in strength, weight, shock resistance, hardness, and shrinkage†	Doors; sash; posts; pilings; building and construction	48	36	3000

TABLE C.13 (continued) Properties and Uses of American Woods\*

Species	Specific gravity		Characteristics	Uses	Weight		
	Green	Dry			lb/cu ft, green	lb/cu ft, air-dry 12%	lb/1000 board ft, air-dry 12%
Locust, black	0.66	0.69	High in shock resistance, weight, and hardness; very high strength; moderate shrinkage**	Mine timbers; posts; poles; ties	58	48	4000
Maple	0.44	0.48	High in hardness, weight, strength, shock resistance, and shrinkage; uniform texture†	Flooring; furniture; trim; spools; farm implements	54	40	3330
Oak, red and white	0.57	0.63	High in hardness, weight, strength, shock resistance, and shrinkage; red†, white‡	Trim; ships; flooring; ties; furniture; cooperage; piles	64	44	3670
Pine, jack			Coarse texture; low strength, stiffness, shock resistance, and shrinkage	Box lumber; fuel; mine timber; ties; poles; posts			
Pine, lodgepole	0.38	0.41	Moderate in weight, hardness, strength, shock resistance, and shrinkage; easy to work‡	Poles; mine timber; ties; construction	39	29	2420
Pine			High shrinkage; moderate strength, stiffness, hardness, and shock resistance	General construction; ties; poles; posts			
Pine, Ponderosa	0.38	0.40	Moderate in weight, shock resistance, shrinkage, and hardness; easy to work †	Building; paneling; sash; frames	45	28	2330
Pine, S. yellow	0.47	0.51	Moderate in shock resistance, shrinkage, and hardness; high in strength‡	Building and construction; poles; pilings; boxes	55	41	3420
Pine, sugar	0.35	0.36	Low shock resistance; easy to work; moderate strength†	Sash; counters; blinds; patterns	52	25	2080
Pine, Western white	0.36	0.38	Moderate in strength, shock resistance, shrinkage, and hardness; easy to work‡	Building and construction; patterns; boxes	35	27	2250
Red cedar, Eastern and Western	0.44	0.47	High shock resistance; low stiffness and shrinkage; moderate in strength and hardness**	Fence posts; closet liners; chests; flooring	37	37	2750
Redwood	0.38	0.40	Low shrinkage; medium in weight, strength, hardness, and shock resistance**	Posts; doors; interiors; cooling towers	50	28	2330
Spruce, Eastern	0.38	0.40	Moderate in hardness, shock resistance, weight, shrinkage, and strength†	Building; millwork; boxes; ladders	34	28	2330

**TABLE C.13 (continued) Properties and Uses of American Woods\***

Species	Specific gravity		Characteristics	Uses	Weight		
	Green	Dry			lb/cu ft, green	lb/cu ft, air-dry 12%	lb/1000 board ft, air-dry 12%
Spruce, Engelmann	0.31	0.33	Generally straight grained; light in weight; low strength as a beam or post; low shock resistance; moderate shrinkage	Mine timber; ties; poles; flooring; studding; paper	39	23	1920
Spruce, Sitka	0.37	0.40	Moderate in weight, hardness, strength, shock resistance, and shrinkage†	Important in boat and plane construction; sash; doors; boxes; siding	33	28	2330
Sycamore	0.46	0.49	High shrinkage; moderate in weight, strength, hardness, and shock resistance†	Boxes; ties; posts; veneer; flooring; butcher blocks	52	34	2830
Tamarack	0.49	0.53	Coarse texture; moderate in strength, hardness, shrinkage, and shock resistance	Ties; mine timber; posts; poles; tanks; scaffolding	47	37	3080
Tupelo			Uniform texture; moderate in strength, hardness, shock resistance; high shrinkage; interlocked grain makes splitting difficult†	Flooring; planking; crates; furniture			
Walnut, black	0.51	0.55	Moderate shrinkage; high weight, strength, hardness, and shock resistance; easily worked and glued**	Gun stocks; cabinets; plywood; furniture; veneer	58	38	3170
White cedar	0.31	0.32	Low shrinkage, weight, shock resistance, and strength; soft; easily worked**	Poles; posts; ties; tanks; ships	24	23	1920
Willow, black			High strength and shock resistance; low beam strength and weight; interlocked grain	Lumber; veneer; charcoal; furniture; sub-flooring; studding			

†Decay resistance low.

‡Decay resistance medium.

\*\*Decay resistance high.

\*From: "Materials Data Book", E.R. Parker, McGraw-Hill Book Company, 1967, pp. 252-255.

Note: For weight-density in kg/m<sup>3</sup>, multiply value in lb/ft<sup>3</sup> by 16.02.

TABLE C.14 Properties of Natural Fibers\*

Because there are great variations within a given fiber class, average properties may be misleading. The following typical values are only a rough comparative guide.

Name	Specific gravity	Tenacity, g/denier	Tensile strength, 10 <sup>3</sup> psi	Elongation at break (dry), %	Standard regain, % of dry <sup>b</sup>	Fiber diameter, microns	Fiber length, in.	Fiber shape and kind	Resistant to
<b>ANIMAL ORIGIN</b>									
Wool	1.32	1.0–1.7	17–29	23–35	15–18	17–40	1.5–5	Oval, crimped, scales	Age, weak acids, solvents
Silk	1.25	3.5–5	90	20–25	10	10–13		Flexible, soft, smooth	Heat, solvents, weak acids, wear
Cashmere						15–16	1–4	Round, scales, soft	
Mohair	1.32	1.2–1.5		30	13	24–50	6–12	Round, silky	Wear, age, solvents, weak acids
Camel hair	1.32	1.8		40	13	10–40	1–6	Oval, striated	Age, solvents
<b>VEGETABLE ORIGIN</b>									
Cotton	1.54	2–5	30–120	5–11	7.5–8.5	10–20	0.5–2	Flat, convoluted, ribbon	Age, heat, washing, wear, solvents, alkalies, insects
Jute (bast)	1.5		50	1–1.5	14	15–20		Woody, rough, polygon	
Sisal (leaf)	1.49	2.2	75	2–2.5	13	10–30	Strand 30–40	Stiff, straight	
Flax (bast)	1.52	4–7		2–3	12	15–18	Strand 40–50	Soft, fine	Age, solvents, washing, insects, weak acids, and alkalies
Kenaf (bast)			45			15–30		Polygon or oval	
Hemp (bast)	1.48			2		18–25	Strand 30–70	Polygon or oval, irregular	
Henequen (leaf)			60				Strand 30–60	Finer than sisal	
Abaca (leaf) (Manila)	1.48	2.3–2.9	100	2–3	13		Strand 30–120		
<b>MINERAL ORIGIN</b>									
Asbestos	2.5		40–200			Various	0.5–10	Smooth, straight	Heat to 400 deg C, acids, chemicals, organisms
Glass <sup>a</sup>	2.5	7–12	200–500	3–4.5	0	Various		Circular, smooth	Chemicals, insects
Silicate <sup>a</sup> (Ca, Al, Mg)	2.85				0				Heat to 900 deg C, most chemicals, insects, rot

*Note:* Wide variations may be expected, especially for different grades of cotton. Wet strength is lower (for rayon, very much lower), but it depends on the duration of soaking. The strength of yarn is only a fraction of the cumulative strength of all individual fibers.

Most fibers exhibit relaxation of stress at constant strain and also increase in elongation at constant load (creep). The stress-strain curve is greatly affected by the rate of extension. When the stress is removed, there is a quick elastic recovery, a delayed recovery, and a permanent set. Hence the elastic behavior of any fiber depends on its stress-strain history. The elastic recoveries of nylon and wool are high; those of cotton, flax, and rayon are much lower.

The heat capacity (specific heat) of most fibers is about one-third that of water.

*Other fibers:* Fur hair is slightly coarser than silk fibers. Camel and llama hairs are almost as coarse as wool but only about one-third the size of human hair. Horse hair is over 100 microns; hog bristles, over 200 microns. Jute, sisal, and hemp are intermediate between cotton and wool. These are rough average sizes, and many natural fibers range 50% above or below such averages.

<sup>a</sup>Here classified as natural fibers for convenience, although they are man-made by processing.

<sup>b</sup>Expected equilibrium moisture regain of dry fiber, in percent of dry weight, when exposed in air at 70 deg F, 65% relative humidity.

TABLE C.16 Properties of Rubbers and Elastomers\*

Elastomers cannot be classified in any brief and simple manner, nor are they well characterized by the usual mechanical tests. The terms *rubber* and *synthetic rubber* are loosely applied to a great variety of elastic materials, from pure gum natural rubber and pure synthetics to cured, compounded, filled, and even reinforced products.

ASTM designations (D1418) by chemical polymer description are used in the following table; yet within each class the properties can vary widely, depending on the exact composition, heat treatment service temperature, and application. Typical uses, such as rubber springs and cushioning, permit an almost unlimited number of combinations of design variables.

Mechanically, rubbers may be expected to lose strength rapidly with increase in temperature, to show a large hysteresis in stress-strain behavior, to exhibit marked creep and set, and to be greatly affected by rates of load application or frequency of repeated stress. "Heat build-up", i.e., increase in temperature in service, as well as deterioration from environment (sunlight, oils, ozone, etc.) will reduce the valuable properties of many rubbers, both natural and synthetic.

The following data apply to typical samples of commercial elastomers for common uses.

## KEY:

A—Acetone	J—Alkalies	S—Salts
B—Benzene	K—Ketones	T—Heat or high temperature
C—Carbon tetrachloride	L—Alcohols	U—Ultraviolet
D—Carbon disulfide	M—Ammonia	V—Vegetable oils
E—Phenol	N—Turpentine	W—Weathering
F—Sulfur compounds	O—Coal derivatives; bitumens	X—Oxidation
G—Glycerol or glycol	P—Petroleum products	Y—Aging
H—Hexane	R—Aromatics	Z—Ozone
I—Acids

## Appendix E. Miscellaneous

**TABLE E.1 Sizes and Allowable Unit Stresses for Softwood Lumber**

**American Softwood Lumber Standard.** A voluntary standard for softwood lumber has been developing since 1922. Five editions of Simplified Practice Recommendation R16 were issued from 1924–53 by the Department of Commerce; the present NBS voluntary Product Standard PS 20-70, “American Softwood Lumber Standard”, was issued in 1970. It was supported by the American Lumber Standards Committee, which functions through a widely representative National Grading Rule Committee.

### Part a. Nominal and Minimum-Dressed Sizes of Lumber\*

Item	Thicknesses			Face widths						
	Nominal	Minimum-dressed		Nominal	Minimum-dressed

				Timbers	5 and thicker		½ off	5 and wider		½ off

<sup>a</sup>Maximum moisture content of 19% or less.

<sup>b</sup>Boards less than the minimum thickness for 1 in. nominal but ¾ in. or greater thickness dry (⅞ in. green) may be regarded as American Standard Lumber, but such boards shall be marked to show the size and condition of seasoning at the time of dressing. They shall also be distinguished from 1-in. boards on invoices and certificates.

\*Reprinted from: “American Softwood Lumber Standard”, NBS PS 20-70, National Bureau of Standards, 1970; available from Superintendent of Documents.

*Note:* This table applies to boards, dimensional lumber, and timbers. The thicknesses apply to all widths and all widths to all thicknesses.

**TABLE E.1 (continued) Sizes and Allowable Unit Stresses for Softwood Lumber**

The “American Softwood Lumber Standard”, PS 20-70, gives the size and grade provisions for American Standard lumber and describes the organization and procedures for compliance enforcement and review. It lists commercial name classifications and complete definitions of terms and abbreviations.

Eleven softwood species are listed in PS 20-70, viz., cedar, cypress, fir, hemlock, juniper, larch, pine, redwood, spruce, tamarack, and yew. Five dimensional tables show the standard dressed (surface planed) sizes for almost all types of lumber, including matched tongue-and-grooved and shiplapped flooring, decking, siding, etc. Dry or seasoned lumber must have 19% or less moisture content, with an allowance for shrinkage of 0.7–1.0% for each four points of moisture content below the maximum. Green lumber has more than 19% moisture. Table A illustrates the relation between nominal size and dressed or green sizes.

**National Design Specification.** Part b is condensed from the 1971 edition of “National Design Specification for Stress-Grade Lumber and Its Fastenings,” as recommended and published by the National Forest Products Association, Washington, D.C. This specification was first issued by the National Lumber Manufacturers Association in 1944; subsequent editions have been issued as recommended by the Technical Advisory Committee. The 1971 edition is a 65-page bulletin with a 20-page supplement giving “Allowable Unit Stresses, Structural Lumber,” from which Part b has been condensed. The data on working stresses in this Supplement have been determined in accordance with the corresponding ASTM Standards, D245-70 and D2555-70.

### Part b. Species, Sizes, Allowable Stresses, and Modulus of Elasticity of Lumber

Normal loading conditions: Moisture content not over 19%, No. 1 grade, visual grading. To convert psi to N/m<sup>2</sup>, multiply by 6 895.

Species <sup>a</sup>	Sizes, nominal	Typical grading agency, 1971 <sup>b</sup>	Allowable unit stresses, psi <sup>d</sup>				Modulus of elasticity, psi
			Extreme fiber in bending <sup>c</sup>	Tension parallel to grain	Compres- sion per- pendicular	Compres- sion parallel

	2 or 4 × 6 +	WC	1 300	775	280	925	1 500 000

Note: Allowable unit stresses in horizontal shear are in the range of 60–100 psi for No. 1 grade.

<sup>a</sup>Grade designations are not entirely uniform. Values in the table apply approximately to “No. 1.” There is seldom more than one better grade than No. 1, and this may be designated as select, select structural, dense, or heavy. In addition to lower grades 2 and 3, there may be other lower grades, designated as construction, standard, stud, and utility. In bending and tension the allowable unit stresses in the lowest recognized grade (utility) are of the order of  $\frac{1}{3}$  to  $\frac{1}{2}$  of the allowable stresses for grade No. 1. The tabular values for allowable bending stress are for the extreme fiber in “repetitive member uses,” and edgewise use. The original tables give correction factors, which are less than unity for moist locations and for short-time loading; they are greater than unity if the moisture content of the wood in service is 15% or less. In general, all data apply to uses within covered structures. From the extensive tables, only the No. 1 grade in nominal 2 × 4 size and 2-in. or 4-in. planks, 6 in., and wider have been selected for illustration.

In a few cases the allowable stresses specified for the Canadian products will vary slightly from those given here for the same species by the U.S. agencies.

<sup>b</sup>Grading agencies represented by letters in this column are as follows:

- NC = National Lumber Grades Authority (a Canadian agency)
- NH = Northern Hardwood and Pine Manufacturers Association
- NL = Northern Lumber Manufacturers Association
- RI = Redwood Inspection Service
- SP = Southern Pine Inspection Bureau
- WC = West Coast Lumber Inspection Bureau
- WW = Western Wood Products Association

<sup>c</sup>It is assumed that all members are so framed, anchored, tied, and braced that they have the necessary rigidity.

<sup>d</sup>For short term loads, these values may be increased: add 15% for 2-month snow load; add 33% for wind or earthquake; add 100% for impact load.

TABLE E.4 Commercial Copper Tubing\*

The following table gives dimensional data and weights of copper tubing used for automotive, plumbing, refrigeration, and heat exchanger services. For additional data see the standards handbooks of the Copper Development Association, Inc., the ASTM standards, and the "SAE Handbook."

Dimensions in this table are actual specified measurements, subject to accepted tolerances. Trade size designations are usually by actual OD, except for water and drainage tube (plumbing), which measures 1/8-in. larger OD. A 1/2-in. plumbing tube, for example, measures 5/8-in. OD, and 2-in. plumbing tube measures 2 1/8-in. OD.

## KEY TO GAGE SIZES

Standard-gage wall thicknesses are listed by numerical designation (14 to 21), BWG or Stubs gage. These gage sizes are standard for tubular heat exchangers. The letter *A* designates SAE tubing sizes for automotive service. Letter designations *K* and *L* are the common sizes for plumbing services, soft or hard temper.

## OTHER MATERIALS

These same dimensional sizes are also common for much of the commercial tubing available in aluminum, mild steel, brass, bronze, and other alloys. Tube weights in this table are based on copper at 0.323 lb/in<sup>3</sup>. For other materials the weights should be multiplied by the following approximate factors:

aluminum	0.30	monel	0.96
mild steel	0.87	stainless steel	0.89
brass	0.95		

Size, OD		Wall Thickness			Flow Area		Metal	Surface Area		Weight, lb/ft

Note: The present trend, especially for sheet and strip, is to quote thickness as decimal or fraction of an inch rather than gage number. ANSI Standard preferred thicknesses have been adopted. These preferred sizes for thickness of uncoated sheet, strip, and plate under 0.25 in. are as follows: .224, .220, .180, .160, .140, .125, .112, .100, .090, .080, .071, .063, .056, .050, .045, .040, .036, .032, .028, .025, .022, .020, .018, .016, .014, .012, .011, .010, .009, .008, .007, .006, .005, .004.

- KEY: (1) Manufacturer's standard for hot- and cold-rolled uncoated carbon steel sheet and most alloy steel sheet.  
 (2) U.S. Standard for cold-rolled steel strip and stainless and nickel alloy sheet.  
 (3) Birmingham or Stub for hot-rolled carbon and alloy steel strip and tubing.  
 (4) Washburn and Moen, Roebling, or U.S. Steel for steel wire.  
 (5) American wire gage or Brown and Sharpe for non-ferrous wire, sheet, and strip.

Dimensions in approximate decimals of an inch.

TABLE E.6 Properties of Typical Gaseous and Liquid Commercial Fuels\*

Gaseous fuels	Composition, percent by volume								Mol wt of fuel	Theor. air/fuel ratio by wt	Higher heating value, Btu/lb <sub>m</sub>	Density, lb <sub>m</sub> /ft <sup>3</sup>
